The Starling Medical College, Columbus, Ohio, held its annual commencement April 14 with a large graduating class. —The sixteenth annual commencement of the College of Physicians and Surgeons, Chicago, its first commencement as a department of the University of Illinois, was held April 19, with 110 graduates. —At the twenty-sixth annual commencement of the College of Physicians and Surgeons, Baltimore, held April 14, thirty-six degrees were conferred. —The Medical College of Virginia, Richmond, held its annual commencement April 16 and the Albany (N. Y.) Medical College, April 20.

Societies.

The following recent meetings are noted:

Connecticut.—The 106th annual of the Hartford County Medical Association, Hartford, April 20.

Georgia.—Georgia Medical Association, Cumberland Island, April 20-23.

Illinois.—County Medical Society, Ottawa, April 26; Fulton County Medical Society, Cuba, April 12; Fiftieth anniversary of the Peoria Medical Society, April 19.

Indiana.—Clark County Medical Society, Jeffersonville, April 12; Knox County Medical Society, Vincennes, April 12.

Kentucky.—Kentucky Midland Medical Association, Georgetown, April 14.

Michigan.—Berrien County Medical Society, Benton Harbor, April 14.

Missouri.—Marion County Medical Society, Hannibal, April 28; Medical Society of City Hospital Alumni, St. Louis, April 21; St. Louis Medical Society of Missouri, April 16 and 23.

New Jersey.—Cape May Medical Association, April 14.

New York.—Binghamton Academy of Medicine, April 19; Oneida County Medical Society, Utica, April 12.

Pennsylvania.—Lackawanna County Medical Society, Scranton, April 12; Lebanon County Medical Society, Lebanon, April 12.

South Carolina.—State Medical Association, Harris Lithia Springs, April 13.

Boston.

ACUTE INFECTIOUS DISEASES IN BOSTON.—During the two weeks ending at noon April 20, there were reported to the Board of Health of Boston the following cases of acute infectious disease: Diphtheria 68, scarlet fever 35, measles 70, typhoid fever 11.

ATTEMPT TO BURN A NURSES' HOME.—Within the past three weeks three attempts have been made to burn the Nurses' Home in connection with the Somerville Hospital. Recently fire was discovered in the attic and before it could be extinguished the building was damaged to the amount of \$500. On the morning of April 1 a fire was discovered in one of the rooms and the occupants barely escaped with their lives. Later another fire was discovered beneath a sink in the second story.

THE MASSACHUSETTS EMERGENCY AND HYGIENE ASSOCIATION held its annual meeting last week. Reports on the work of organization were submitted and the following officers elected: President, James Minot, M.D.; secretary, Miss Rosa L. Dexter; treasurer, Charles Fry; executive committee, Mrs. Kate Gannett Wells (chairman), Miss Ellen Tower, Mrs. F. H. Williams, Miss Ida Mason, R. W. Greenleaf, M.D., A. K. Stone, M.D., James Minot, M.D., Francis C. Gray, Horatio Davis.

THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.—The regular meeting of this society was held Monday, January 10, with Dr. A. L. Mason in the chair. Several interesting cases were reported and Dr. J. W. Farlow read a paper on "Some Forms of Adenoid Disease which are Often Overlooked and Conditions which Simulate Adenoid Disease." He made the statement that with the exception of traumatism no child under 6 years of age ever has carache without adenoids. He also called attention to the importance of enforcing deep nasal respiration after an adenoid operation.

APPOINTMENTS AT THE BOSTON DISPENSARY.—Dr. Alfred A. Wheeler, James L. Stone, William P. Cones and George A. Harlow have been appointed assistant surgeons; William Coggeswell, assistant surgeon to the department for diseases of the genito-urinary system; Sidney A. Lord, assistant physician to the department for diseases of the nervous system, and Drs. William H. Grant, Charles N. Barney, Frederick J. Cotton, Elliott P. Joslin, Frederick W. Pearl, Franklin S. Newell and Joshua C. Hubbard, district physicians.

THE BOYLSTON MEDICAL PRIZE.—The Boylston Medical Prize of \$150 has been awarded this year to Dr. Guy Hinsdale of Philadelphia for an essay on "Acromegaly."

Detroit.

THE DETROIT MEDICAL AND LIBRARY ASSOCIATION.—At the meeting April 18, Dr. George W. Moran read a paper on "Cervical Adenitis in Childhood," classifying the disease as follows: Acute, simple chronic, tuberculous and syphilitic. The acute variety he stated is almost always caused by infection from some disease of contagious structure such as catarrh of nose and throat, decayed teeth, middle ear trouble, unhealthy tonsils and stomatitis, but may also be caused in a mild form by any of the eruptive fevers. The diagnosis is easy except when the sub-mandibular or sub-lingual gland is involved; then mumps, spinal caries and edema must be differentiated. The treatment consists in looking well to the condition of the teeth, gums, tonsils and nasopharynx, as in seventy-eight cases of the author's forty-six were caused by carious teeth and suppurating gums, and fifteen by enlarged tonsils and disease of the nose and throat, and in the use of hot applications, liniment or ointment of belladonna combined with opium. When pus forms evacuate as soon as possible. Simple chronic adenitis is also caused by infection as in the acute variety, though of a milder character. Certain skin affections may also cause it. This variety may be confounded with the tuberculous, but age,

history and family history ought to aid in arriving at a definite conclusion. In the latter form, too, there is suppuration, caseation and adhesion, which never occurs in this simple variety. The treatment is tonic after removal of cause and application of pot. iod. ointment. In tuberculous adenitis the upper deep cervical glands are generally the first to be affected, and at first may thus be mistaken for the simple variety. The treatment consists in removing the patient to the most favorable environments, tonic medication, change to more equable climate when possible, and in case of suppuration or caseation, incision and drainage. Excision should be practiced only when the glands are superficial and movable. The author tried nuclein injection in three cases, in one of which there was improvement, in the others none. The syphilitic variety is comparatively a rare affection, and is usually accompanied by glandular enlargement throughout the system. It is almost always met with only as a complication of some other syphilitic manifestation. The diagnosis is easy, antisyphilitic treatment is to be practiced.

THE MICHIGAN STATE MEDICAL SOCIETY will meet in Detroit on the 5th and 6th of May. Every arrangement is being made to have this session of the Society surpass any of its previous meetings.

HEALTH REPORT for the week ending April 23: Number of cases of diphtheria remaining, 5; scarlet fever, 23; total deaths, 112; births, 77.

Philadelphia.

PHILADELPHIA MILK SUPPLY.—Philadelphia's milk is better than its water according to the report of recent chemic analyses made by chemists F. A. Geuth and C. B. Cochran. The subject was recently agitated and was brought to the notice of the State Secretary of Agriculture, Thomas J. Edge. Great care was exercised to have samples of milk from several sources, therefore one-fourth the total number (200) were obtained from the milk depots when first reaching the city, one-fourth from the cows of the dealers, one-fourth from milk jugs in private houses and one-fourth found in the various restaurants of the city. Instead of being artificially prepared and well watered, in many instances there really was an excess of fats, indicating a large amount of cream. In other samples the fats were below the normal average. This variety was more prevalent in the restaurants of the city.

THE UNIVERSITY OF PENNSYLVANIA AND ITS DENTAL DEPARTMENT.—To conform with the high standard of requirements in its other departments, the faculty have decided to require more preliminary education before matriculating anyone in the dental department, and the following have been agreed upon: For the session of 1898-99 a certificate of high school entrance; for the session of 1899-1900 a certificate of two years high school attendance; for the session of 1900-01 a diploma of an approved high school having a three years' course, or a certificate showing three years attendance at a high school having a four years' course, or certificate from other schools showing equivalent education. Or in lieu of such diploma or certificate the candidate will be required to pass a preliminary examination.

DIPHTHERIA DURING WAR TIMES.—While detailed on duty on board the monitor *Nahant*, at the League Island navy yard, Philadelphia, a member of the New York naval reserves became stricken with a well marked case of diphtheria. Thorough disinfection on board, however, has prevented the disease from gaining a foothold among the crew.

STATUS OF SMALLPOX IN PHILADELPHIA. No further cases of this disease have been reported to the board of health other than the two recently noted. Both cases are being cared for at the Municipal Hospital. As was stated in a previous issue of the JOURNAL, the Municipal Hospital is badly overcrowded, and it is thought an ordinance will soon be brought before the City Council to provide for a separate building for the treatment of this disease.

NEW PROFESSOR OF GENITO-URINARY DISEASES.—Dr. Edward R. Kirby, who for the past twelve years has been assisting in the surgical department of the hospital of the University of Pennsylvania, has lately been elected clinical professor of Genito-urinary diseases at the Medico-Chirurgical College.

TYPHOID STATISTICS OF PHILADELPHIA FOR THE PAST FIVE YEARS.—For the purpose of comparison the report regarding typhoid fever in the above-named city is herewith appended:

1894.			
	Cases.	Deaths.	
January	137	43	
February	125	18	
March	157	20	
1895.			
	Cases.	Deaths.	
January	238	36	
February	294	64	
March	184	48	
1896.			
	Cases.	Deaths.	
January	174	34	
February	160	23	
March	177	21	
1897.			
	Cases.	Deaths.	
January	173	36	
February	114	18	
March	179	27	
1898.			
	Cases.	Deaths.	
January	790	65	
February	681	75	
March	332	54	

The report for infectious and contagious diseases for the past two weeks is as follows:

	This week.		Last week.	
	Cases.	Deaths.	Cases.	Deaths.
Diphtheria	81	22	78	13
Typhoid Fever	31	8	55	15
Scarlet fever	68	1	46	4
Total	190	31	179	32

The death rate in Philadelphia per 100,000 population in typhoid fever is 40.

Cincinnati.

THE SOCIETY FOR MEDICAL RESEARCH held its regular monthly meeting Thursday evening April 14 at the Ohio Medical College. The program of the evening was as follows: "Scabies Norwegica" remarks and demonstration, by Dr. A. Ravogli; "Newer Histology of the Brain," by Dr. D. I. Wolfstein. Discussion.

THE forty-second annual commencement of the Cincinnati College of Medicine and Surgery took place at the Scottish Rite Cathedral April 13. There were in all twenty-six graduates, of which four were women. Dr. S. C. Ayres, the dean, made the address. The valedictory was by Dr. J. A. Johnston. A banquet followed.

THE next annual meeting of the Ohio State Pediatric Society will be held at Columbus on May 3 and 4.

ACADEMY OF MEDICINE.—The regular meeting of the Academy of Medicine was opened April 18 by the report of Dr. J. C. Oliver, the committee on transportation to the coming meeting of the AMERICAN MEDICAL ASSOCIATION in Denver. The rate reported was one round trip ticket at the cost of fare one way plus two dollars; trip by way of Chicago or St. Louis, or via one city one way and the other on return without extra charges; one dollar additional for every stop over outside these large cities; same rates for wives and families; fifteen making the same trip will be allowed a private car; seventy-five, a special train. Dr. Oliver was followed by the guest of the evening, Dr. Maurice Carnes, the representative of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, who urged coming by way of Chicago stating the pleasure it would give Chicago physicians to entertain the members of the Academy of Medicine.

Report of cases: Dr. Max Thorner, "Complete bony occlu-

sion of the external auditory canal, left ear." The man had noticed gradual diminution of hearing for some years, but had not given it attention until several months ago; it was not an exostosis, for a probe could not be entered at any point either at the circumference or at the center. The operation to be performed on this case will be an incision behind the auricle as in beginning the regular mastoid operation, loosening the attachment with a periosteotome, chiseling away the bony mass, and skin grafting the denuded surface in the hope that the bone will not reform. Dr. Thorner also reported a case of radical mastoid in a child two and a half years old, who had been suffering from a foul-smelling discharge for many months with no improvement under treatment. The operation disclosed caries, and all rotten bone was removed; the peculiar feature was the brain concussion which lasted nearly a week; the child was much emaciated and approaching dissolution when the operation was performed, but when presented at the Academy was apparently healthy in every way. Dr. Merrill Rickets showed a case of tubercular glands of the neck removed by a posterior incision. Dr. Robert Hill three months ago reported a case of ligation of the common carotid and subclavian on the right side for aneurysm of the ascending aorta; in a week the man was up, and the external tumor had greatly diminished in size. A week ago the man died suddenly, and postmortem examination revealed a rupture of the right auricle. The specimen was presented. A cause for this rupture could not be determined. The speaker mentioned cases of heart rupture in which the heart was entirely normal, and stated that had he known there was so much fusiform dilatation to the aorta he would not have operated, but with the saccululation as evidenced by the external tumor, he thought he was justified in the operation and would do the same under similar circumstances. The clot present in the sacculated portion he thought proved that some benefit had been derived from the operation. Dr. Heady reported a case of perforating round ulcer of the duodenum and showed specimen; the ulcer was perfectly round, looking as though it had been punched out with some sharp instrument; was situated just one-half inch outside the pyloric orifice; about two inches away was another ulcer partially healed; the patient had died thirty hours after the onset of the acute symptoms; he did know the cause of the ulceration; there was no history of superficial burns; the literature of the subject presented in over 8000 autopsies, but twelve cases, seven of which were in males. Dr. Rickets then read a paper on "Deaths (ten), Surgical and Causes." The cases were as follows: meningitis in child, gangrene of leg in a man aged 59 years, brain abscess in a child aged 4 and following middle ear disease, peritonitis from ovarian disease, intestinal obstruction from a band, followed by strangulation, fibrosarcoma of the uterus, stone in the bladder complicated with chronic morphinism, empyema of the gall-bladder with rupture, cerebellar abscess following middle ear disease, fracture of the base of the skull in a man 69 years of age who had been kicked by a horse, and where superior maxilla had been driven into the throat and interfered so much with respiration that the pieces were removed, but the patient died two hours after operation. Dr. John Landis read a paper entitled "Paralysis of Sphincter in Clamp and Caution Operation; Muscles of the Pelvic floor." Discussion.

"Luz," or the Sacrum.—A rabbinic name for the os sacrum was "luz," or the "resurrection bone," it being a bone especially difficult of destruction, and therefore the supposed germ of the survival of the body, and in this connection Dr. Cormer unearths the following from Butler's Hudibras:

The learned Rabbins of the Jews
Write there's a bone, which they call Luz,
I' the rump of man, of such virtue
No force in nature can do hurt to.
From whence the learned sons of Art
Os sacrum justly call the part.

THE PUBLIC SERVICE.

Army Changes. Official List of Changes in the Stations and duties of officers serving in the Medical Department, U. S. Army, from April 16 to 22, 1898.

Lieut.-Col. Albert Hartsuff, Deputy Surgeon-General, will proceed from Hdqrs. Dept. of the Lakes, Chicago, Ill., to Chickamauga Park, Ga., for temporary duty.
Major Egon A. Koerper, Surgeon, is relieved from duty at Ft. Crook, Neb., and will report by letter to the commanding officer, Dept. of the Missouri, for assignment to duty as chief surgeon of that Department.
Capt. Rudolph G. Ebert, Asst. Surgeon, is relieved from duty at Ft. Missoula, Mont., and will proceed to Tampa, Fla., and report to the commanding officer, Seventeenth Infantry, for duty.
Col. Charles R. Greenleaf, Asst. Surgeon General, will transfer his duties pertaining to the medical supply depot at San Francisco, Cal., to Lieut.-Col. Johnson V. D. Middleton, Deputy Surgeon-General, chief surgeon, Dept. of California, who will perform them in addition to his present duties, and will also perform the duties of chief surgeon, Dept. of the Columbia, during the remainder of the absence on leave of Lieut.-Col. William D. Wolverton, Deputy Surgeon-General.
Major John Van R. Hoff, Surgeon, is relieved from duty at Vancouver Bks., Washington, and from the temporary charge of the office of the chief surgeon, Dept. of the Columbia. Col. Greenleaf and Major Hoff will repair to Washington, D. C., and report in person to the Surgeon-General of the Army for duty.

ORIGINAL ARTICLES.

THE CLIMATE OF COLORADO FOR RESPIRATORY DISEASES.

BY CHARLES DENISON, A.M., M.D.

Emeritus Professor of Diseases of the Chest and of Climatology,
University of Denver; Ex-President of the American
Climatological Association, etc.
DENVER, COLO.

PART I. THE ATTRIBUTES OF CLIMATE AND AIR-RAREFACTION.

The request of our Chamber of Commerce Committee, to give the facts concerning the kind of climate we have in the vicinity of Denver, is complied with reluctantly, only because the author fears his inability to do the subject justice in the space allotted. The evidence depended upon is too voluminous to mention it all, and the author will have to refer the reader to his other writings¹ for the details, and to state some positive conclusions, which might otherwise be challenged if they were not based upon a twenty-four years residence in Colorado, in which time some thirty-five hundred pulmonary cases have been recorded. Experience is what tells, and the experience of the medical profession in Colorado unquestionably sustains the conclusions here presented. We may differ as to the advisability of inviting the weaker, the invalid class to come out here and live. The fact remains, however, that our recovered invalids have ceased to be a detriment to the communities in which they have mingled and that they constitute, in a large degree, the life and success of our new civilization. It is therefore with hope and confidence that we refer to the proofs which substantiate our experience in this elevated section.

Before proceeding with the summary of the evidence on hand, let it be admitted that some medical minds are not wholly in accord on the question of climatic effects in the causation and cure of disease, probably because of local bias or that their estimation of the attributes of climate is measured by a limited experience. This is unfortunate, but has to be admitted if any credence is to be given to such medical gatherings as the late "Congress of Medico-Climatology, Auxiliary of the World's Fair." At that meeting reports were presented from widely separated districts, high, low, inland, sea bounded and both within and without the United States. These reports were so exaggerated in praise of each special locality represented, that the listener, without a settled basis of

judgment as to preferable climatic attributes, would be deceived into acquiescence to absurd propositions in turn alike contradictory. This going into the minutiae of local weather statistics (as the daily range of temperature, or the extremes reached in a given month or year) as many have done, is of questionable use.

Such a mass of unessential particulars, however laboriously tabulated, only consumes time in its study and detracts from the consensus of knowledge needed.^{2 3}

Climate has to do with many special diseases, and its effects upon kidney diseases, the nervous system, age, sex and occupation would be instructive if time permitted to consider them; but we are now to study chiefly the class of diseases with which climate has both the greatest causative as well as curative effect, namely:

Chronic pulmonary diseases.—This study⁴ of the air with regard to the causation and cure of respiratory diseases ushers us immediately into a controversy which has more than any other occupied the attention of climatologists for the past thirty years. It is the question of air pressure and the susceptibility or adaptability of the human organism to it under varying states of health and disease. Without seeming to controvert the great general argument, that of purity of atmosphere, always used by those who do not admit the importance of this air pressure consideration (for the pure air argument is an admitted issue and needs no proof), the question of altitude or sea level pressure can not, we believe, be ignored in the climatic prescription we are required to inscribe.

The purpose in the following presentation is to ignore any given locality and consider the chief attributes, those variously considered as most effective in the production of what is called climate. These are; 1, elevation above the sea (rarefaction); 2, dryness of the air, both absolute and relative; 3, temperature of the air, whether cold, cool or warm; 4, sunshine, its preponderance or average daily duration at a given place, which introduces the important questions of cloudiness and the diathermancy (clearness) of the air; 5, the winds which introduce many correlated causes, such as the seasonal changes, the configuration of the earth's surface at a given place, the ocean tide, storm winds, daily or periodical currents of mountain or sea air, etc; 6, the character of the soil, which is of great importance with reference to the proportion of forests to dry land, the contiguity of the sea or large bodies of water, and the general configuration of the earth's surface; 7, the variability or equability of the

¹ "The Rocky Mountain Health Resorts." Cloth and Paper covers. Houghton, Mifflin and Co., Boston, Publishers. Descriptive of the interior health resorts of the United States. "The Climate of the United States in Colors." The W. T. Keener Co., 95 Washington St., Chicago, Publishers. A graphic description, in twelve colored charts and eleven tabulations, of over 8,000,000 separate observations of the United States Signal Service Bureau, given in Annual and Seasonal representations of cloudiness, temperature, rainfall, winds and combined humidity statistics, for the professional and lay reference. "The Preferable Climate for Consumption." Congresses of 1876 and 1887. Somewhat elaborate arguments founded upon the analysis of climatic attributes independent of locality.

² To be commended: A recent historical and geographical study of the climates of that part of the world inhabited by the English-speaking people, issued by MacMillan and Co., London and New York, on "The Treatment of Lung Diseases by Climate," by Dr. C. Theodore Williams.

³ "A Handbook of Medical Climatology" by S. Edwin Solly, M.D., M.R.C.S., Lea Bros. and Co., Publishers, Philadelphia and New York 1897.

⁴ Largely drawn from the Author's article on "Climatic Treatment," in Foster's Practical Therapeutics.

air-temperatures, which are largely relative, the former to altitude and the latter to the sea; 8, the electric condition of the atmosphere, which mysterious agent is also decidedly relative to mountain and sea currents, but which is none the less important as affording desirable stimulation.

In choosing from such attributes the most desirable combination for the arrest of lung disease, the writer feels called upon to explain why he does not place altitude the most important of all, at the head of the following list. It is; 1, because altitude shows its effect upon each important attribute, and thus in a fair analysis gets a reasonable allowance of praise; 2, because the special consideration of altitude is needed in presenting air-rarefaction as a potent force in treating respiratory diseases, hardly second, by itself, to any other attribute, yet at least entitled, in the minds of the majority of physicians, to hold the third place in such a classification.

Dryness is preferable to moisture.—We should have a line of demarcation between these two opposing qualities of the atmosphere, so that there could be no confusion in the use of the terms dryness and moisture. It seems that the average of the combined hygrometric conditions of the atmosphere, for the whole inhabited portion of the country, is a fair criterion between these two opposite conditions, and we will accept this as the line of definition between dryness and moisture. Temperature must be accounted for, as the capacity of the air to hold moisture varies so greatly, according to this record, the variation being from about one-half grain of vapor to the cubic foot, at zero, to nearly twenty grains at 100 degrees F., when the air is saturated. This was the foundation of the writer's rule for the determination of moisture and dryness.⁵

This rule was based upon a calculation of a table representing the average of the combined humidities of the air (cloudiness, absolute and relative humidity) for the whole United States, and for every degree of temperature. The average of these three evidences of humidity were found to be 44.5 per cent. for the time (average proportion of each day) the sky was clouded, 67 per cent. of saturation, for relative humidity, and, consequently, 67 per cent. of the weight of vapor the air could hold, for absolute humidity.

The graphic illustration of this rule on colored maps, compared with mortality statistics, shows that the arrest of consumption is far more surely to be accomplished as you go toward the extreme of dryness, from the mean, than toward the extreme of moisture. Indeed, it is the very moist climates which furnish most of the cases to be arrested in the dry sections.

The chief argument in favor of atmospheric dryness is based upon the increased transpiration of aqueous vapor from the lungs, in a degree according to the dryness of the air breathed. The germs of disease need warmth and moisture in which to live and flourish, a climate tempered and constituted according to the requirements of their peculiar existence. It is reasonable to infer that the preference shown by tubercle bacilli for a *locus habitandi* in pulmonary tissue is in no small degree governed by the catarrhal or other products of inflammatory change which clog or close the air cells and connecting tubes. If these secretions or morbid products could be removed at the

same time the bacilli which inhabit them were thrown off, the result would certainly be salutary. These could be so expelled if they could be reached by the inhaled air, and this in turn had the requisite absorbent power. This absorbent power is just what the inhaled air possesses through its quality of dryness, and in proportion thereto. Absorption takes place through the difference in percentage of saturation (relative humidity) between the inspired and the expired air, and also much more through the difference in quantity (absolute humidity) between the moisture inhaled and that expelled. This especially takes place if cold air is inhaled, which is raised to the temperature of the body and then has greater power for holding moisture. Valentine, Sanctorius, Lavoisier, Seguin, Dalton and others have investigated the subject of transpiration, but not to differentiate between persons at different altitudes and temperatures. In this analysis of humidity statistics, ("Moisture and Dryness") the writer made an attempt to compute the difference in transpiration. He took Draper's statement as the basis of his calculations, namely, that the dew-point (the temperature at which the vapor present would make saturation) of the expired breath is 94 degrees, F. Three kinds of estimates were made by way of comparison.

1. Difference in vapor transpiration between a warm moist (Jacksonville, Fla.) and a warm dry climate (Yuma, Ariz.), of about the same elevation and temperature. This calculation, for an ordinary sized man, gave for Yuma, 3987 grains vapor exhaled, and 3073 for Jacksonville, or an excess for Yuma over Jacksonville of 864 grains a day, when no exercise was taken. When one makes allowance for the increased respiratory activity due to exercise, he can realize the still greater difference in transpiration as shown by Dr. Edward Smith's statement that, "one at sea level, walking at the rate of three miles an hour, consumes three times as much air as when at rest." The ordinary exercise of a man would make this difference in transpiration under the given conditions equal to about a gill in twenty-four hours.

2. When we make this calculation for places of different temperatures and elevations, the evidence becomes still more conclusive, for cold is probably the most important factor in the production of dryness, and elevation is not far inferior, because it, in turn, produces cold as well as expansion in the volume of the air. It is right to allow for the elevation an equivalent to the proportionate rarefaction of the air, that is, if the pressure is one-fifth less (twelve pounds to the square inch) at Denver than at Jacksonville, then one-fifth more air will be breathed at the former station. In this calculation we will assume a good sized man, 30 years old, as breathing both in Denver and Jacksonville twenty breaths a minute and thirty cubic inches to a breath (Dr. Grehant), ordinary exercise included, and for the same season at each place. This gives by the same method of reckoning, vapor exhaled above that inhaled in twenty-four hours, 8900 grains for Denver and 4939 for Jacksonville. This is an excess of transpiration of moisture in favor of Denver of 3961 grains, or over 8 ounces, in twenty-four hours. Two important considerations would further add to this effect in favor of the high altitude station: *a*, the expansion of the air, in being raised in the respiratory tract from the lower temperature of the atmosphere to the higher temperature of the body; *b*, the increased amount of

⁵ "Moisture and Dryness." Report made to the American Climatological Association, 1884, Rand, McNally and Co., Chicago.

exercise naturally indulged in at the higher station, due to the stimulation of the cold, and the possible electric influence, quickening and deepening respirations.

3. For the purpose of still further comparison, it is instructive to take a cold, dry place in winter (Cheyenne, Wyo.) and a warm, moist one in summer (Charleston, S. C.) on the same basis (though Cheyenne is a little more elevated than Denver). The calculation results in vapor exhaled above that inhaled in twenty-four hours, 9881 grains in Cheyenne and 3615 in Charleston; excess of respiratory evaporation in favor of Cheyenne in winter, over Charleston in summer, is 6266 grains. If the two modifying effects previously mentioned were to be taken into consideration, together with the usually increased activity of the respiratory organs in such cold, as compared with such warm weather, the result would show for Cheyenne in winter a daily passing of vapor from the lungs of at least a pint more, than for Charleston in summer.

Coolness or cold is preferable to warmth or heat. The importance of cold in the composition of the curative atmosphere we seek is hardly less than that of dryness. In fact the two are so interdependent and necessarily associated that they can not be easily separated. If the thermal units coming from the combustion of effete material which should be thrown off through the lungs may be considered as indices of the natural cleansing of the system, then the tremendously augmented expenditure of heat units required in cold climates to maintain an equilibrium of bodily temperature must be credited for this great purifying influence. This potent effect is still further increased by the greater transpiration of vapor from the lungs in dry, cold climates, above proved to take place, because such transpiration is represented by the latent heat of vaporization, also necessarily thrown off. This temperature problem naturally introduces the following considerations:

1. How much atmospheric humidity is influenced by the element of temperature is shown by the sensory effect of cold. It is through conduction chiefly, that the body parts with its heat. Evaporation and radiation together do not equal this power of conduction, which the atmosphere, in common with everything that touches the body, possesses. Now, the conductivity of the air depends greatly upon its moisture. It is with the air as it is with solid substances. A bar of iron feels very much colder than the same shaped piece of dry pine, though they both may be of the same temperature. The iron is by far the better conductor, just as moist cold is, compared with dry cold air. To those who have never previously experienced a dry, cold and sunny morning on the eastern slope of the Rocky Mountains, there is a deception in the sensation of cold, which is equivalent to from 15 to 20 degrees. One seems to be in a much warmer atmosphere than that in which he really is. Temperature then is a relative attribute, and can not be considered as independent of humidity. Besides, the drying effect of cold upon the atmosphere, low temperature will be found to have other useful effects in the arrest of consumption.

2. Heat expands the air, so that the contrast between the temperature of the atmosphere and that of the body indicates the swelling effect cold air produces when full breaths are taken. Any doubt about this may be settled by trying the simple experiment

of breathing one's utmost into a spirometer in a heated room when the air is frozen outdoors. Then step to the door, take a full breath and try again; the difference should in part indicate the expanding force heat imparts to the inhaled air. This lung-stretching capacity of inhaled cold air is especially appreciated by those who hold that it is most often the lack of use which paves the way to infiltrations or tubercular deposits in the tops of the lungs. It is to such secluded places in the lungs that the expanding air carries the evaporating influence of dryness.

3. Cold stimulates and heat depresses. This is a generally accepted proposition, which needs no extended elaboration. The sensations themselves are a good guide, and the colder the air the more stimulating it is. "A bright sun and blue sky overhead, a clear and quiet atmosphere, distant sounds transmitted to the ear through the still air, combine with the charms of the scenery to produce such buoyancy of spirits that a man is braced and invigorated for almost any exertion." (Dr. A. Tucker Wise in "Alpine Resorts.") It is in harmony with this stimulating effect of cold, that the respiratory function is diminished in activity in hot climates, and an increased amount of blood is found in the lungs of residents in cold countries, as shown by Parkes, Rattray and others. Dr. Francis, of the Bengal army, found, from a large number of observations, that the lungs were lighter in Europeans in India than the European standard. The increased quantity of blood circulating through the lungs means increased oxidation of the blood and renewal of tissue. The pulmonary lymphatics join in the increased activity, the nervous system is exhilarated, and the whole nutrition is improved.

Cold not only stimulates and encourages needed exercise, but under certain conditions it may result in a desirable sedative effect. The sleep which comes at night after a day's exhilaration and excitement induced by cold is the most refreshing of all rest.

The influence of cold in destroying or impeding germ life, especially the life of the bacillus of tuberculosis, is a most important consideration. This is diametrically opposed to the fostering of nearly all germ life by moist and mild heat. If one has ever "camped out" on the top of a Rocky Mountain pass, he will never forget the stillness of that insectless and germless locality. The nightly freezing of the air, together with its dilution through lessened air pressure, is enough to render germ life impossible. But the best evidence is that which has reference to the climate and natural life conditions of the bacillus, limited as they are to a narrow range of temperature.

"The air we inhale does not perhaps so often contain the fully developed bacillus as is supposed by many people, for this microbe does not thrive in the air at the usual temperature, but requires, according to Koch, a temperature approaching that of the human body. Its growth entirely ceases below about 82 and above 107 degrees F., and it thrives best at about 98 to 100 degrees, while other pathogenic microbes have a much wider field—for instance, the anthrax bacillus, which grows luxuriantly between 67 and 74 and up to 110 degrees."⁶

The study of seasonal effects in phthisis shows the salutary influence of cold. This may appear strange to those people of the North Atlantic, Middle and Lake States who flee south in terror of the winter

⁶ Dr. Weber, in the "Croonian Lectures on Chronic Pulmonary Phthisis."

weather. True, yet do not thousands yearly leave moist England for a winter stay in the frozen uplands of Switzerland? The force of this consideration is not appreciated except through a recognition of the importance of dryness. Notice on the winter seasonal map, previously referred to, the prevailing northwest, west and southwest winds, some one of them everywhere moving toward the great interior lake region of the United States. The cooling of these air currents, causing condensation of vapor, with the addition of moisture already existing, is enough to produce cloudiness in this interior lake section for from six to eight-tenths of the winter season. The effect of the cold moisture renders this a climate to be avoided by enfeebled lungs. However, where the other attributes—dryness, elevation and sunshine—are favorable, the winter is the best time of the year for most consumptives. In cases suitable for positive treatment, these favorable climatic conditions, by means of this cooler temperature, can be increased to a climax of success not otherwise obtainable. The experience of invalids in Colorado bears out this conclusion. It is to secure the cooler temperature in summer time that some of the consumptive patients from the plains are sent higher up to the parks and divides of the Rocky Mountains. The effect of the change is very generally good, and a tubercular fire, which had rekindled in Denver on the advent of warm weather, has been arrested, as appearances indicated, by a sojourn in a cool park 8000 feet above the sea.

Rarefaction is better than sea-level pressure.—The consideration of elevation is divided into: 1, the effect upon other climatic attributes. Then aside from this there is the mechanical effect of rarefaction; 2, the physical influence upon man in health; 3, the influence in disease and the experience of invalids; 4, the evidence of a certain immunity from consumption.

We have already referred to the influence of rarefaction in producing dryness and coolness. Its effect upon sunshine, diathermancy, variability of temperature, wind movements, radiation, evaporation, etc., will appear as we proceed. The expansion of the air is equivalent, in degree, to any given elevation. The additional space occupied carries with it its due proportion of atmospheric moisture. In localities favorable for health resorts, this deprivation more than counterbalances the condensation of vapor by cold. The result is a total decrease of moisture, which is shown by a small percentage of cloudiness, a low relative and a very small absolute humidity. Then through its expansive effect as well as by its influence upon other producers of dryness, elevation is a powerful agent in controlling atmospheric humidity. As to temperature, elevation has a constant effect in the production of cold. It is differently estimated by authors, but does not vary greatly from about 3 degrees decrease in heat for each 1000 feet rise in elevation. In some favorable localities, such as the eastern slope or base of the Rocky Mountains, this lowering temperature is neutralized by local conditions, such as the excess of sunshine, the character of the soil—being dry and sandy—and the protection of mountain ranges, which drain the western, humid air currents of their moisture, so that the isotherms, as a given elevation is reached, continue directly in a western course until the very high mountains turn them southward.

The physical effect of rarefaction upon human beings.—Dr. Jourdanet, of Paris, gave us a most com-

plete and elaborate exposition of the physiologic effects of the diminished air pressure, and not content with this analytical investigation, he induced Paul Bert to work out by experiment, chiefly on the life of birds, the effects of the equivalents of various elevations, even up to starvation limits, as to the supply of oxygen. These and many other studies might be elaborated if space permitted. Ignoring their trivial differences, we will state only settled conclusions. Lessened atmospheric pressure leads to an equivalent loss of oxygen, which deficiency, Parkes, in his "Practical Hygiene," says is not felt by animals till a rarefaction equal to 14 per cent. is reached. This loss is about equivalent to an elevation of 10,000 feet, and many animals do begin to live an abbreviated existence at this height. But there are previous effects which man can appreciate all the way from 3000 to 6000 feet, at which latter limit the air is one-fifth rarefied. This appreciation, in a state of rest, is from nothing to considerable, according to the sensitiveness of the heart or lungs, or both of them. There is an adaptability of these organs in perfect health which more than compensates for a rarefaction of one-fifth, so that only a pleasant exhilaration is felt, even with moderate exercise. Much exertion strains this adaptability, and a degree of breathlessness may be reached, which indicates a decided deficiency of oxygen compared with the immediate requirements. However, it is not the point of injury or danger that is here referred to, but the altitudes which produce healthful and well-borne respiratory activity when at rest and even during moderate exercise. The effects of altitude vary according to the pulmonary or cardiac susceptibility of an individual, and are divided into, 1, first effects; 2, permanent effects or acclimatization.

On the arrival of a healthy individual in a high altitude, say a mile above sea level, there is first an increase, both in frequency and depth of respiration. When adjustment to the new conditions has taken place, which requires a variable period, according to the altitude and the individual, the respirations are not nearly so much increased in frequency during rest, but the depth of breathing is habitually greater. This is shown by the large spirometric records of those who reside at great elevations, and the increased size of their chests both in adults and children. This is farther shown by the necessity of the climatic change to supply the usual, if not augmented, demand for oxygen, which is to meet an increased combustion or change of tissues. The increased exhalation of carbonic acid and the lower air temperature, as well as the increased chest measurements in those invalids who are not so far advanced in disease but that the affected lung tissue can be returned to use (an effect noted in the writer's cases, as well as those of C. T. Williams, Weber and others), are in perfect accord with the habitual use of more air for all the purposes of living in high altitudes. The heart and lungs having a reciprocal relation to each other, are both proportionately more active. In imperfect respiratory states, such as incipient consumption, the impeded circulation feels the stimulation, especially in those portions of the body which were the least active before—in the lung periphery and the capillary system generally. The result is a more perfect circulation of the blood and oxygenation of tissues, also of carbonaceous and effete materials. The supply and waste are more completely attended to, and the "sewer work" of the respiratory system is more complete. There

is a change in the relative density of the air in the lungs, due to this increased activity and to the fact that the air breathed is rarefied. There exists an alternate greater pressure or density of the air with expiration, and diminished pressure or rarefaction during inspiration, with each respiratory act, compared with the air pressure outside the body, and also compared with the usual change of density of air in the lungs during respiration at sea level. Here is found the best form of "pneumatic differentiation" because it is natural. This increased outward pressure within the lungs is especially salutary in the chronic thickenings, etc., of the lining membranes of the air cells and bronchial tubes, and it has a tendency to open up passages closed by disease and non-use to the entrance of pure, dry air. Some of the worst cases of consumption are those where the air can not reach the microbes or morbid products.

The augmented respiratory activity.—This with the rush of blood into and through the pulmonary capillaries, which seem to disturb the judgment of a few physicians with reference to the liability to the occurrence of pneumonia or pulmonary hemorrhage in high altitudes, requires some further explanation.

There is no cause for fear of hemorrhage if proper precautions are taken as to extreme elevations and the character and stage of the disease existing in the lungs. There should be no spots of softened lung tissue, especially near the root of the lung which have not had time to be protected by nature's great conservative process—the deposition of fibrous or hardening tissue. Only those patients should be sent to very high places who can bear the rapid expansion and augmented circulation without rupture of blood vessels. In portions of the lungs where there is no softening this increased pressure acts helpfully on the distended vessels, just as a properly adjusted bandage does on a swollen limb. The alternate crowding of the dry air against hypertrophied or diseased alveolar walls, and the suction directly applied through the push given to the circulation, tend to clean out the products of morbid processes and relieve congestion. There is, as mentioned by Dr. C. T. Williams, 1. hypertrophy, or more complete development of certain portions of healthy lung tissue; 2. emphysema (dilation) of other portions, especially of those in the neighborhood of the consolidations and cavities. This increased action and the stretching help to isolate caseous or tubercular portions, prevent the spread of infection, and promote cicatrization or fibrination of the affected parts.

As to pneumonic and hemorrhagic cases, the writer's later experience tallies well with that tabulated in his report to the International Medical Congress of 1876, in which were presented his first records of 202 consumptives who had spent a total of 350 years in Colorado. The pneumonic cases and the hemorrhagic, without cavity, were by far the best influenced of all varieties. Very acute cases, during the time inflammation or hemorrhage is active, need to be treated upon the rest principle, and such should be excepted from the foregoing.

Altitude of immunity from phthisis.—There is presumptive proof that those climatic conditions which prevail where phthisis seldom or never originates are best suited to arrest the disease when it has commenced elsewhere. Reference must be briefly made to the considerable evidence of medical writers in favor of an altitude of approximate immunity from consump-

tion which, with us in America, ranges not far from 8000 feet in the southwestern part of the United States; to nearly 5000 on our northern boundary.

As to the quality of the climate which affords this partial immunity, Jaccoud of Paris, says, "altitude is the most important element; climates with a high altitude, having tonic and stimulating effects, can alone confer on the inhabitants absolute or relative immunity from pulmonary phthisis." While altitude is the governing element, all the associated favorable conditions of the atmosphere, somewhat in the order in which we have named them, seem to go hand in hand until they reach a climax of success in conferring a more or less complete immunity from consumption upon the residents at the given altitude. In illustration of this influence, the records of mortality from phthisis in the city of Denver and in Colorado generally, might be cited. Up to the year 1896, out of twenty deaths from this disease, eighteen or nineteen were from the imported cases, a fact which should always be taken into account as explaining the mortality from consumption in this State. Since the date given, the consumptive mortality in the city of Denver has shown an increase undoubtedly due to local conditions in which a greater liability to infection has to be admitted. Even thus the proportion of indigenous cases of tuberculosis to all deaths is now and for some time will continue to be far below that of any American city of like size.

Sunshine is superior to cloudiness.—There is little necessity of advocating the utility of sunshine. Proof is sufficient, but is necessarily combined with that of other climatic attributes. Every one acknowledges the benefit of sunshine, though in summer time he may have a personal preference for shade. Undoubtedly the effect of light upon man's physical and moral well-being is analogous to the fructifying influence of the sun's rays upon the vegetable kingdom. All life depends upon sunshine, and for successful existence must have it. The proportion of sunshine to cloudiness depends on the length of the day, on the exposure of a place, as on whether or not it is concealed in a valley, and on the cloudiness of the sky. The distribution of clouds in the United States is computed by the Signal Service Bureau in tenths of obscuration of the sky, and from these observations the percentage of cloudiness, and conversely of approximate sunshine, may be noted for the whole country. Reference is made to the first of the charts in the "Climates of the United States, in Colors" already referred to, for an eleven year average of the distribution of cloudiness. The variations of cloudiness range from above 60 per cent. of the time over the interior lake region down to less than 30 per cent. in the southwestern portion (New Mexico and Arizona). Taking so broad a field into calculation, a striking harmony is noted between cloudlessness or sunshine, and other favorable attributes. They all go together. A preponderance of sunshine should be mentioned as favoring the possibility of the desirable outdoor life, and also of camping out in summer time.

(To be continued.)

Hooks for Mastoid Operations. P. J. Zaalberg has devised a couple of rake-like hooks to hold the soft parts spread in these operations. The hooks are slipped into knots at the ends of a piece of rubber tubing that passes around the head. The teeth of one are so arranged as to form an angle of 30 degrees with the pulling line, thus holding the parts without drawing them up.—*Cbl. f. Chir.*, April 2.

MEDICAL OR TISSUE ASEPSIS.

Read at the Thirteenth Annual Meeting of the Fifth District Branch of the New York State Medical Association, held in Brooklyn, N. Y., May 25, 1897.

BY T. J. MCGILLICUDDY, A.M., M.D.

NEW YORK, N. Y.

MOTTO:—CLEANSE AND STRENGTHEN.

Medical asepsis is but the inward application of the principle contained in the ordinary surgical asepsis, supplemented by the enhancement of the bactericidal properties of the blood serum. The words cleanse and strengthen include all the essentials of tissue or medical asepsis. Wherever water will flow, no matter how small the stream, it will cleanse, and the cleansing power will be proportionate to the size and number of the streams. Water has been used for ages for its curative action in disease, but not, to my knowledge, with the idea of establishing an aseptic condition of the tissues by effecting and maintaining tissue cleanliness. While to many, the presentation may seem a novelty, it is founded on years of careful study and practical application. The absence of any authorities on tissue asepsis as such, and its proven value in practice, will be sufficient apology for this paper.

Tissue asepsis has become, in my practice, a firmly fixed principle of treatment, both capable of absolute clinical and practical demonstration and gratifying in its results. The skepticism with which the theory of internal or tissue asepsis may possibly be received will no doubt be based on a wrong conception of the conditions which require its use and an imperfect knowledge of its practical application. In the uncleanness of the tissues we have the products of fermentation or decomposition absorbed either through the lymphatics or blood supply, or it may be inflammatory exudates or other products, which have not been eliminated by the fluids of the body. But if there is an increased ingestion of water of carefully regulated temperatures and in stated quantities, along with systematized exercise of the muscular tissues, then the fluids becoming more abundant and less dense will cause the waste of the body and the pabulum for the development of micro-organisms to be removed, with the result that finally a sterilized surface of tissue is obtained in many cases. In internal or tissue asepsis we can do no more in one particular than in external or surgical asepsis. By the latter, we can ordinarily only remove the detritus or debris, leaving a clean surface so that no micro-organisms can have food or habitation resulting in development. While in tissue asepsis we can not only cleanse, but in many cases, so strengthen and invigorate the tissues as to increase its resistance to the spread of infection. The cause of the grave results in internal disease is presence of decomposing exudates or retained nitrogenous waste products. These exudates or effusions undergo decomposition or putrefaction as the result of the advent of micro-organisms. Micro-organisms primarily and waste products and weakened tissue secondarily, are the two factors in the production of the decomposition or disease. Hence micro-organisms are not the sole factor in the cause of disease. The devitalized or deteriorated structure, effusion, or exudate must be present before putrefaction can take place, and where there is no putrefaction or decomposition there is no constitutional disturbance which in the body could imply the presence of non-vital tis-

suess or exudates and micro-organisms. Devitalized structure, or those of lowered vitality often readily degenerate into pus, as the result of irritation, suppuration being the degeneration of imperfect or devitalized tissue caused by the inflammation, the result of the effects of the micro-organisms. As in an external wound we remove from the surface the materials which undergo septic changes in order to establish resolution, so in internal inflammation the need of tissue lavage is imperative and possible, and is immediately beneficial within the circulatory field. The filtration of water through the body is the result of definite physical and chemic laws, the nature and workings of which are becoming more clearly defined and understood, and it would be childish to presume that we have reached the limit of knowledge on this question, while in all other fields the searching torch is held aloft, seeking to enlarge the vision of the truth-seeker. The physical theory of medical asepsis is based upon anatomic and physiologic investigation, study and practice. One has but to thoroughly familiarize himself with the conditions which regulate the endosmosis of fluids through animal tissues in order to clearly understand the peculiar phenomena connected with medical asepsis.

If, in ordinary surgical asepsis, the value of the solvent properties of water is admitted, is it difficult to comprehend that the same properties and offices are not lessened by ingestion? It has been truthfully said that, with the exception of air, water is the most transient of all the elements received into the body. It is a general eliminator—nature's own cleanser. Its increased use augments the elimination of the waste of the body, increasing the metabolism of tissue, and in the words of Ringer "increasing vigor alike of body and mind." Our body corresponds exactly in many ways with artificial mechanism. The organs of secretion and excretion are similar in their action to an ordinary filtering apparatus. As the activity of filtration depends not only on the size of the pores in the filter, so the diffusion also varies according to the nature of the material of the porous body. The different membranes of the body can change their operations by the activity of the contracting tissues. This change is automatic; it completes and perfects other bodily functions. The amount of liquid increment equals the amount of liquid decrement in the urinary secretion, perspiration and watery vapor from the lungs. In speaking of the physiologic action of water taken inwardly, if we were to start at the very beginning and describe all the bearings that water has in the physiology of the body, while it might make one's conception of the elucidation of the method much easier, such a description is apparently unnecessary, as the important part played by water in the economy is well known to all. Still, a résumé of a portion of the subject is not out of place here.

Valentin says, "a filtrum is any porous material. The molecules of the body might be said to filter water in the same way that it passes through sand in the earth, taking up all sorts of minerals and earthy salts. When some kinds of freestone, powdered charcoal, flannel, or unsized paper are used, the fluid is passed through for the purpose of separating it from the material suspended in it."

Water, in passing through the body, gives up its salts in a similar way, and also absorbs the waste while in transit, which it carries out through the emunctories. Impure water brings disease to the tis-

sues: pure water carries it away from them. In studying the physical properties of the human body, the limitation of our senses, even with microscopic aid of the highest magnifying power, makes them insufficient to show us many of the minute but important constituents of the various tissues. The ultimate molecule is so small that the human eye can not see it. In the arrangement of every organism it moves in limited spheres. It is, as Valentin says, the smallest possible but independent, and by this arrangement there are many important advantages. Subdivision into the smallest masses is of advantage in the enlargement of the free surfaces, for thus more molecules of the solid and liquid substances are brought into mutual contact. The minute subdivision of the circulating fluid enables it to give off nutriment to the various tissues, and, making an exchange of gases with the atmosphere in the skin and lungs, its basis being water, it takes up the waste of the tissues by its solvent power. The endosmosis of fluids through the bodily tissues, following mechanical and chemical laws with an anatomic basis, allows the water to filter out through the tissues as urinary secretion or perspiration. Minute anatomy, physics and chemistry explain clearly the mechanics of medical asepsis. The cleansing function is increased when larger surfaces of the circulating fluid come in contact with the walls of the vessels; the enlargement of surface for bathing purposes, which is obtained by means of the capillary system and the minute lymphatics, is enormous. When we consider the chemical and physical properties of the tissues, the advantage resulting from their extremely minute division is readily shown. The suppleness and pliability of the organs depend in a great measure on the amount of water they contain, as when thoroughly dried by heat they are extremely brittle. Five-sixths of the body can be volatilized under moderately high temperatures.

In a consideration of the velocity of water filtering through the body, the form of the aperture of exit, the shape of the stream, the nature, diameter, and course of the tubes through which the fluid mass is driven, and the resistance of the bodies with which it meets on the way, the adhesions to the walls of the tubes and friction against them, are the important circumstances which control the degree of rapidity of the filtration. The fine canals which are found in our body are much more minute than any capillary tubes with which hydraulic experiments have been made. The fluid which is driven through them generally passes through the same medium. At other times, liquid masses are expelled into the air. The velocity with which a liquid flows through a capillary tube to pass into another uniform liquid, varies with the nature of the moving fluid. Warmth hastens the passage of fluid through minute tubes in a great degree. This explains why the higher temperature in warm-blooded animals is of great advantage in this respect, and why warm water is more readily diffusible and more readily absorbed. It also shows the reason the flow of blood in the cutaneous capillaries is retarded, or even checked, when the temperature of the skin is much lowered by the application of cold.

Every part of an organ is a mass which is traversed by interstices in all possible directions. The peculiarity of structure gives the tissues when dry the power of absorbing fluids, and the amount of the absorption or imbibition depends upon the nature of the organ-

ized body and of the fluid together with its temperature, the pressure and the duration of the operation. Watery solutions are inferior to pure water, since a certain amount of attractive force is expended in the powers of solution. Besides this, many fluids such as pure water and all incompletely saturated solutions not only penetrate the interstices of the organized mass, but can chemically take up some of its constituents and very essentially change others. The filter through which the fluid passes is a porous partition which first absorbs the liquid constituents of the fluid submitted to it. The pressure received by the numerous strata of the mixture then drives the fluid through the pores as through a system of fine tubes.

Very considerable amounts of pressure do not only increase the rapidity of transudation, but also extends the skin itself and by thus enlarging the interstices allows thicker fluids to pass through. The albumin of the serum of the blood is unable to pass with the pressure of a column of small height, but with increase of pressure it soon transudes. The evaporation which takes place through porous partitions, as in the lungs, constitutes a kind of inverted filtration. It is quite unnecessary that the liquid mass should be in immediate contact with an organized partition. If it can evaporate with the existing temperature and pressure, it saturates with its vapor the space of air above it, if an apparatus is used, and this vapor transuding the organized partition becomes free as soon as the exterior atmosphere has also become saturated though in a less degree. If the interstices of a porous body imbibe a fluid of any kind, it will, to a certain extent, be condensed when it is in immediate contact with solid walls. And if there are solid matters in solution these may to a great extent be kept back during the filtration.

The fundamental condition for endosmosis is the presence of fluids between which there exists an affinity, and which are separated by a porous partition. It is, therefore, only miscible fluids that are susceptible of diffusion. When fluids are driven through by mechanical pressure the resistance is greatly increased by a diminution of the diameter of the conducting tubes. If these tubes are of small caliber the influences which differences of hydrostatic pressure will exert on the two fluids may be disregarded as unappreciable. Under these circumstances diffusion is independent of hydrostatic influences. But where one fluid exerts a much stronger pressure than the other, the organized membrane will yield, acquiring larger pores, thus offering fewer obstacles to transudation so that there will be not only diffusion but also filtration. The behavior of the partition in respect to the form, size and subdivision of its interstices, and the attraction which its walls exert on the liquid which they contain is capable of great variation. They vary, not only in different animal membranes, but also in different portions of them. These circumstances influence the strength and rapidity of diffusion. The manifold character of the partitions through which are transmitted the liquids in our bodies, allow of an infinite variety of diffusive results, and as porosity is often affected by the influence of the nerves and other circumstances, the same membrane may at different times produce very different results.

When two different solutions are separated by a porous partition, a chemical attraction is added as another cause of diffusion. If thicker membranes are made use of in diffusion, such as the coats of the small

intestine, the aorta or vena cava. The simplest endosmotic fluid transudes in a very short time. In the living tissues diffusion is almost instantaneous when the necessary conditions are present. Abdominal pressure by manual treatment has an important influence on the absorption and diffusion of water taken into the stomach and intestines.

In the normal tissue, owing to its porous structure, there are numerous and mutual actions between the juices of the body and the fluids which come in contact with its organs. Special means of favoring these actions allow foreign solutions to be taken up and absorbed in large quantity. That solution of solid bodies, which is necessary to diffusion, may be affected by the organic mixtures themselves. The solutions first gain the nutritive fluid which soaks the tissues, and then pass immediately into the blood. It is often necessary that they should first enter the lymph and flow with this liquid through the absorbents or lymphatics and then become mixed with the blood: therefore, we distinguish between immediate and mediate entrance into the blood, or between entrance directly and entrance into the blood through the lymph. The porosity of animal membranes is capable of being altered by numerous circumstances. The relaxation of the liminary walls leads to the enlargement of their interstices. These may also be dilated under the influence of very powerful pressure. If, as an example of the absorption of the alimentary substances, we introduce into the stomach a large quantity of spring water containing .05 per cent. of solid residue, it will dissolve many organic matters which it meets with, and which the neighboring juices of the body retain in a less diluted form. The first current of diffusion is, therefore, concerned with a nutrient and secretive fluid which moistens the coat of the stomach. The blood which contains the most solid matter will act with greater energy than the lymph, which is more watery. The process of diffusion therefore, must continue until the densities of the two fluids become equal to each other. The blood and lymph of the wall of the stomach would thus become much diluted and the remainder of the contained water will be correspondingly concentrated. This is what would occur if the solutions remained at rest, but since the blood and lymph are in active movement, new portions of these dense mixtures are continually exposed to the operation of diffusion. This arrangement, therefore, which holds good for absorption generally assists in the interchange of fluids in a most important manner. The lymph flows more slowly than the blood, and this explains why the greatest part of the water we drink enters the blood and decreases the percentage of solid residue therein. That the purely physiologic method is sufficient to explain satisfactorily the phenomena of blood washing in the living body, a study of the processes through which water goes when taken into the system in absorption, and following it through to its final excretion is all that is necessary. The fluid secretions of the glands of the mouth and stomach contain about 99 per cent. of water, and yet after having extracted nutritive material from the food, they still contain more water than the blood or lymph. This explains why the more dilute solutions disappear so readily in the stomach itself. That the process of absorption goes on in the intestines is due to its large supply of blood vessels and lymphatics. The chief object of the lymph and chyle seems to be that of ensuring a normal mixture of the blood. When the

blood passes through the capillary vessels of the various parts of the body, it allows the exudation of a fluid which is more diluted than its own serum. This fluid permeates the tissues, giving up to them the necessary nutritive substance while taking up or washing out the waste matter. In this way we get a more watery residuum, containing less of nutritive matter and more of the waste of the body. The absorptive canals are probably intended to withdraw this fluid, and their contents are improved by a process of diffusion with the blood, the lymph glands having a very essential function in this respect.

To recapitulate the subject of absorption:

During the passage of blood through the capillary system a very important series of changes take place in its ingredients. These ingredients, whether in the blood or lymph, are transformed to tissue, while at the same time they are replaced by other ingredients which are taken by absorption through the adjoining parts. Water is the basis of all the fluids of the body, and the phenomena of absorption, with endosmosis and exosmosis, depend upon it. Endosmosis is most active when the temperature is moderately raised: pressure also exerted upon fluids in the body favors their endosmosis: in fact, the imbibition of the waters by the tissues is an endosmosis, while its secretion and excretion is an exosmosis, or in other words, the whole process is simply a filtration through the body.

The process of endosmosis is essentially one of imbibition or absorption of the liquid by an animal membrane composed of organic ingredients. Over twenty-five pounds of the animal fluids transude through the internal membrane and are restored to the blood by reabsorption in the course of a single day. It is by this process that the natural constitution of the parts, though constantly changing, is still maintained in its normal condition by the movements of the circulating fluids, and the incessant renovation of their nutritious materials.

In medical asepsis our agents are the eliminatives: these are remedies which increase gland secretion, and the most important is water.

It is much more important, by working toward medical asepsis, to insure proper excretion and elimination in fever, than to rely on other means for reducing temperatures, as for many reasons it is not always wise to attempt to reduce temperature by drugs. We supply the system with alkalin salts in an abundance of water, in order to ensure proper excretion and to maintain the action of the kidneys, the bowels, and skin. Chlorid of sodium and the alkalin potash salts also tend to the increased elimination of urea. Laxatives are of value in medical asepsis, as, by ensuring proper excretion, there is an exosmosis toward the intestines, and the abnormal products present in fever are thus removed from the blood, in a great measure, in many cases. The temperature frequently falls, and great relief is experienced as the result of their use. The natural watery excretions of the skin and lungs are considerable, and nature increases these after imbibition of a large quantity of water. In the lungs, water diffuses through the mucous membrane and is evaporated. In bronchitis (and this is especially to be noted in children), the use of an abundant supply of water is extremely beneficial.

Böcker demonstrated that the blood contained more water in a quarter of an hour after swallowing large quantities of the fluid but that within half an hour there

was return to the usual amount. Lichtenstein asserts that, "even in the case of a larger quantity of water being absorbed in a short time and the intensity of the discharge of water from the body falling far short of the intensity with which it is taken in, the current of the blood protects itself from being overloaded with water, which does not distribute itself to the blood current alone, but to the fluids of the parenchyma all over the body. Water saturates and fills all tissues and tissue spaces." He italicizes the following assertion: "We have at hand in copious water drinking a means of subjecting the whole system to a powerful washing out. A consequence of this is the temporary increased excretion of certain products of change of tissue." The increase of salts in the urine after copious water drinking has been proved by the experiments of Beaqueral, Chossat, Lehmann, Genth, Mosler and Falk.

Does the increased current, which permeates the tissues after large amounts of water have been taken, favor the conditions for the decomposition of albumin? Does it increase this and thus augment the excretion of urea? Bischoff, Böcker, Voit, Hermann and others answer this in the affirmative. Winternitz says, "simultaneously with the increased discharge of water by the kidneys, however, the solid constituents of urine will be eliminated in greater quantities, particularly the urea. Metabolism in the nitrogenous formations of the body is therefore materially promoted thereby. The conclusion that oxidation increases and becomes more complete under the same influence, may be drawn from the diminution in the amount of and complete disappearance of oxalic acid, which before the increased supply of water was very abundant. Moreover the increased oxidation following increased water drinking may be proved, directly, by the increased carbonic acid excretion and assumption of large amounts of oxygen. Salts likewise and inorganic materials, such as the potassium salts, which chiefly spring from the metabolism of the muscles, the fire-proof salts of the bones, and the phosphates and sulphates of the brain and glandular functions are eliminated in great quantities. The universal stimulation of retrograde change and acceleration of tissue metabolism caused by increased methodical drinking of common water is still too little utilized in therapeutics."

Wm. H. Thomson in his recent lectures says: "One of the most important functions of the liver is the separation of effete nitrogenous matter from the blood; and the imperfect discharge of this function is always indicated sooner or later by the accumulation of urates and oxalates in the blood, and by an excess of uric and oxalic acids in the urine—a condition which, if continued, induces a gouty diathesis, biliousness, constipation, piles, slow digestion, loss of elasticity of mind, etc. Not infrequently patients with these symptoms, failing to obtain relief from medicine, go to a mineral spring or some hydropathic establishment, where they are markedly benefited: for water itself, if taken in sufficient quantity by increasing the fluidity and consequently the solvent power of the blood, is often an effective remedy in these cases."

George Henry Fox says, "it is quite certain that few people drink too much water, and I feel sure that many unpleasant feelings and symptoms of actual disease would quickly disappear if the sufferers only appreciated the value of this best and cheapest of all remedies. The interior of the body needs cleansing

as much as the exterior, and a liberal supply of pure water in the treatment of our patients will often bring about the desirable results which drugs have failed to accomplish."

Lichtenstein says, "we make the most extended use of this washing-out power of water in therapeutics. When it is the object to bring exudations to absorption, to wash out accumulated particles from the blood and from the tissues, and to remove certain poisons from the system, and to wash out blocked-up urinary tubuli, copious water drinking may be used efficaciously in many cases. As water in large quantities is better borne by the stomach taken warm than cold, the use of the former is preferable and is more rapidly diffused."

Other excretions besides that of urine are influenced. The sensible and insensible transpiration of the skin is increased in many diseases. The cleansing action of cold water is familiar as exciting the peristaltic action and as an aperient.

The *New York Medical Journal* of October, 1894, contains the following: "Elimination of the diseased products is of extreme importance in all acute and chronic diseases. If the diseased materials are allowed to remain the growth of bacilli will be correspondingly great. When the vitiated matter is removed by elimination the disease can not be so severe, as then there is an internal asepsis which prevents bacillary development. The eliminating organ should be stimulated, and hot water is the blandest and most efficacious means of accomplishing it." In the *Medical Record* of Nov. 9, 1895, I also wrote: "If the constitution is improved and the pabulum upon which the bacteria thrive removed or its formation prevented, their development is hindered or entirely checked and thus the severer forms of inflammation are obviated. A plant can not grow upon a rock or thrive upon barren soil, and so it is with all forms of life even the minute organisms. The substances upon the surfaces of wounds which cause the development of micro-organisms and thus produce infection are readily removed by the most important and chief means for all sterilization, that is the mechanical purification by washing and cleansing with water. Why should not the substances in the interior of the organism, which are the pabulum for bacterial development, also be removed, at least to a great extent, through the channels of the body which terminate directly in the emunctory organs. It is quite possible that the sewage system of the tissues when properly stimulated in the work of elimination will carry along in its circulation much of the material which causes infection, and thus produce what might be termed an internal sterilization or asepsis. Many seem to think that because a germ has once entered the human body it can not be removed until it is thoroughly digested, but why should not cleanliness applied to the internal organs whenever possible aid in the elimination of micro-organisms?"

Dr. Charles H. Shepard of Brooklyn published in the *JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* Sept. 14, 1895, an exceptionally able article on "The Bath in Modern Medicine," which should be read and studied by every practitioner.

Medical asepsis is the result of prophylaxis in the individual. By inhaling only pure air and by taking only sufficient quantities of nutritious sterile food into an aseptic alimentary canal the lymphatics and the blood are kept free from the irritating products of fer-

mentation or putrefaction. If decomposition is further prevented by a plenitude of the natural digestive secretions and pure water is taken in proper quantities and of stated temperatures along with the employment of regular systematized, strengthening exercise of the different bodily functions and with proper psychic conditions, medical asepsis is established and continued. A definite knowledge of the method of medical asepsis and its indications will alone lead to its satisfactory employment and the results will as in the use of any other agent be much more beneficial when it is methodically employed in a proper manner. Like other agents it has its limitations.

The following cases show the practical application of the principles here spoken of. In any method practical or clinical experience is the proper test upon which we must rely.

Case 1.—Sadie W., age 24, complexion fair, rather tall and slender, countenance pale; general expression heavy and listless; has a badly developed thorax and the muscles of the chest and neck are thin and also poorly developed. Family history good. Her occupation has been an indoor and sedentary one requiring a stooping posture, thus interfering with the respiratory function. The ventilation of her work room was also defective. For several years she has suffered with constipation and attacks of indigestion and biliousness. During the summer of 1895 she was feeble, easily fatigued and short-winded on going up-stairs. October 20 after a cold, a dry hacking cough came on which was much worse during the night from 2 to 4 A.M. Expectoration after a time became copious and muco-purulent. December 15 she was taken with an attack of pleuritis of the base of the right lung; after about a week pain came on also at the same place in the left side. During this time she was under the care of her family physician, who gave her the usual symptomatic treatment. Jan. 3, 1896, a specimen of her sputa showed the presence of tubercle bacilli. The patient continued to grow worse, and after giving a bad prognosis January 8 he turned the case over to me for treatment. I found the patient in bed with a temperature of 100, heart's action weak and rapid, heavily furred tongue, complete loss of appetite, constipation, shortness of breath, night sweats, hands and feet cold. Her menstruation had been absent for four months with the exception of one day. She had a disrelish for fats and wholesome food and had morbid cravings for pickles, pastry and strong coffee. The physical signs showed bronchial catarrh, a slight infiltration of the left apex and pleurisy at the base on two sides.

January 15 examination of the sputa again showed the presence of tubercle bacilli. January 24, after sixteen days' treatment, examination failed to show the presence of any tubercle bacilli. February 8, one month after commencing treatment, she was discharged as cured, entirely free from cough and with a good appetite, digestion, color and greatly increased in strength, flesh and spirits.

The treatment consisted of internal and external hydrotherapy, curative exercise, manual treatment (massage) and special feeding. The internal hydrotherapy consisted of the ingestion of two quarts of hot water daily, taken an hour before each meal and half an hour before retiring. After the fifth day the patient was required to go out daily for an hour or two, well protected, regardless of clouded skies, east winds or snow, for proper oxygenation of the blood. There is much more danger in staying in-doors than in going out into the fresh air, even when the patient suffers with some muscular weakness. It is a physiologic principle that the only way to retain or increase the muscular strength is by its daily use. No drugs were employed, not that they are not often useful and in advanced cases mitigate many distressing symptoms, but in this case they were not considered necessary.

To increase the vigor of the body in a constitutional disease like tuberculosis, which is also infectious, we should never depend exclusively on drugs, but adopt a course which will stimulate and assist nature to

throw off the disease, and we should force the nutrition at the same time to the highest point with easily digested nitrogenous food and a sufficiency of carbohydrates. The great principles underlying oxidation, elimination and repair should guide us in the treatment of this very frequently fatal disease.

Case 2.—Fannie C., age 20, weight 125 pounds is a tall and anemic brunette with hectic flush. July 30, 1896, she stated that about two months previous she was taken with a dry and persistent cough. It occurred occasionally during the day. After a time it grew worse and became very severe at night, weakening her very much from loss of sleep. During one of these attacks of coughing a hemorrhage of the nose came on. About two weeks prior to my seeing her she was taken with an attack of vomiting; this caused a severe hemorrhage which quite exsanguinated her. She was compelled to remain in bed from weakness for five days. She complained of much soreness of the trachea and bronchi; bowels always regular; some tenderness in the hypogastric region; always menstruates excessively for five days.

On physical examination I found increased vocal fremitus over the lower half of the left lung. There is some dullness on percussion; abundant mucous râles. August 1 a specimen of her sputa showed the presence of tubercle bacilli. August 20 she stated her cough had ceased for four days. Under forced coughing she raised a little mucus which did not show the presence of any tubercle bacilli. She has gained seven pounds in weight, now weighs 132 pounds and is robust and strong. The treatment is similar to that in Case 1.

Case 3.—S. J., age 42. About twenty years ago this patient had attacks of diphtheria, scarlet fever and typhoid fever. After this she was troubled by a cough which lasted for a considerable time; this disappeared. About five years ago she had an attack of pleurisy which kept her in bed for three weeks; this left and was followed by a cough which came on gradually. She was seen by her physician, who said that she had "a general catarrh of the stomach, throat and lungs and phthisis." She gradually became worse, a large cavity forming in the right upper lobe. Last June she was in very bad condition, with severe night sweats, emaciation and frequent attacks of weakness; had three hemorrhages, one very severe. Her expectoration was very profuse and muco-purulent. I placed the patient under careful dietetic treatment and the methodical use of internal and external hydrotherapy for relative medical asepsis. Cold baths were used for their tonic effect in giving exercise to the vasomotor system, with the result that her general nutrition was greatly improved. She had taken creosote and cod liver oil with no apparent effect. She has been under treatment for ten months with great benefit. She does considerable housework, feels very much stronger, has gained in weight and her expectoration is not nearly as profuse as formerly nor her cough so troublesome. She still has tubercle bacilli in her sputa.

Case 4.—S. M., age 30, rather short, stout, blonde; addicted to the beer habit; has an excessive craving for carbohydrate food. Two of her sisters died of consumption and her mother of cancer. I saw this patient April 21, 1893. There was some elevation of the temperature and an extremely rapid pulse. The tongue was dry and heavily coated and the teeth were covered with sordes. I found the left lung completely consolidated from apex to base with an unresolved pneumonia, from which she had suffered six weeks previously. She had been constantly under treatment by her physician during this time without appreciable benefit. I felt that the case was a serious one and that it would require the earnest co-operation of the patient in a careful regimen if recovery was to follow. The indulgence in alcoholics and carbohydrates to excess combined with her sedentary life, surcharged her system with the products of fermentation, and this acted as a predisposing cause to the pneumonic attack. I considered the case an excellent one to test thoroughly the resources of my method of treatment by medical asepsis, and I feel that had the treatment been continued for at least two months she would have made a perfect recovery. After but a few days' treatment the tongue became clear and moist, the temperature and pulse became nearly normal. The patient went about and in a month the exudation in the lung was apparently two-thirds resolved and was rapidly undergoing complete disappearance, when the family moved to a small town in the suburbs. The patient now took milk punches with no restriction as to carbohydrate, discontinued the method of internal asepsis and other strengthening modes of treatment, thus renewing the supply of fermentable material in the blood, which in the tissues

became the nidus and pabulum for micro-organisms, with the result that in about three months the patient was dead.

Case 5.—T. C. J., age 22, a telegraph operator. A sister and several cousins died of tuberculosis. He has been for years living on insufficient and improper diet, principally of improperly cooked carbohydrates. His cough was very severe; copious muco-purulent expectoration containing tubercle bacilli. Under a course of internal hydrotherapy, curative exercise, with an out-door life and manual treatment, and some correction of his dietary he made a slow but perfect recovery.

Case 6.—K. C., age 30, school teacher; several relatives died of tuberculosis. Owing to improper food, worry and hard work she became excessively anemic. There was a spot of infiltration with mucous râles in the upper lobe of the right lung. She was under the care of two physicians, who found tubercle bacilli in the sputum in moderate numbers. They gave a bad prognosis. Under internal hydrotherapy and careful dietetic management, increasing the amount of digestible proteids taken daily and without the advantages to be derived from mechanical treatment and external hydrotherapy, she made a rapid and complete recovery, having gained twenty-three pounds in weight within six months.

Case 7.—M. C., aged 20. When I first saw this patient in 1893 the left lung was consolidated as the result of an unresolved pneumonia; mitral regurgitation was also present as a result of rheumatic endocarditis which had occurred some years previously. There was apparently perfect compensation, the heart being only moderately enlarged. Her diet had been so insufficient in nutrient materials that nature had been unable to resolve the exudate which filled the lung substance. She had been seen by three physicians who gave a bad prognosis, nevertheless, under the method of tissue lavage in a very short time the lung cleared up perfectly. The dietetic treatment hastened the convalescence, and now, after four years, she feels perfectly well.

Case 8.—M. B., age 42. Jan. 20, 1897, when I saw him he had been constantly undergoing drug treatment for digestive derangement for the past eleven months; had but little appetite and digestion was poor; was much emaciated; extremely despondent. Under two weeks' treatment by internal hydrotherapy and manual treatment he entirely recovered, and says that he now eats and assimilates more at a meal than he formerly did in three weeks.

Case 9.—F. C., aged 22. A year ago last April, after an extreme hemorrhage following a miscarriage, she began to have a slight cough and pain in the apex of the left lung. She has continued to grow worse ever since. Her cough is especially troublesome at night. Shortly before consulting me her expectoration became very copious, frothy and muco-purulent. There were night sweats and chills; her appetite was very uncertain; she was very despondent. She takes four glasses of hot water daily with an increased quantity of proteid food, and two months after beginning treatment was very much improved in strength and spirits. Her cough is not now so troublesome as formerly and her expectoration is less copious and thinner.

Case 10.—P. H. M., aged 75; of vigorous constitution; has until this winter remained well, in spite of the consumption of large quantities of sugar, pastry and strong coffee, hard boiled eggs and fried steak. Has had two attacks of what was termed "grip," characterized by neuralgia, pain in the head, sweats and chilliness. His grip was simply the outcome of loading the tissues with the products of fermentation from a catarrhal digestive tract. His last attack was accompanied by severe vomiting and abdominal distension and tenderness. Under the use of hot water for two days his tissues cleared up, the epigastric tenderness became less pronounced and his appetite and digestion returned. He entirely recovered within two weeks.

Case 11.—B. A. W., age 54; consulted me May 1890. He has been in the habit of drinking three glasses of whisky before meals daily for the last eight or ten years. Eats nothing in the morning except tea and bread; at the other meals his food is wholesome. There is considerable tenderness over the epigastrium; his tongue is heavily coated; bowels regular; has gout in right big toe joint. I made local application to the toe joint and ordered him to drink very large quantities of a pure soft hot water daily. He has continued this and has had no trouble from the gout since beginning treatment—over six years ago.

Case 12.—W. H., aged 30; bookbinder. When I first examined this patient in February, 1896, there was considerable consolidation of apex of the right lung. He had had several hemorrhages and his cough was severe and distressing. The expectoration was profuse, muco-purulent and contained numerous tubercle bacilli. Under treatment he has gained in weight from 124 to 140 pounds. The apex expansion in the

right side has increased very much and the consolidation has almost entirely disappeared; he coughs less frequently and the sputa is very scant and contains no bacilli. His color is ruddy, appetite excellent and he feels very strong. The treatment here also consisted of the establishment of relative medical asepsis by internal hydrotherapy, mechanical and manual treatment, along with a proper dietary containing much minced beef and milk.

Case 13.—Mrs. R., aged 38; is anemic, emaciated, neurasthenic and weak. Her appetite and digestion are poor and there is constipation and much flatulence. Under tissue lavage with the addition of manual, mechanical and dietetic treatment she improved rapidly in strength, and from 118 pounds in weight she increased within three months to 130, and says she has not felt so well in many years.

Case 14.—D. D., aged 38; engineer; works at night; family history good; had a severe attack of pleurisy in 1892, from which the convalescence was slow and imperfect; bronchitis was also present and the sputum was copious and muco-purulent. There was marked shortness of breath and diminished respiratory murmur over the front and upper portion of the right lung. The diagnosis of phthisis pulmonalis was made, but there was no examination of the sputum for tubercle bacilli. Under tissue lavage and dietetic treatment he improved and with the exception of occasional slight asthmatic attacks now enjoys fair health. At present there is no cough or expectoration.

Case 15.—M. G., aged 17; at college; is chlorotic and weak. She says that she has been delicate all her life and has consulted her family physician about once a week ever since she can remember. She has a number of malarial symptoms, flushes, perspiration and headaches; her appetite is very poor. She suffers with chronic constipation, and nearly every week has a sore throat. Micturition is frequent and her urine deposits large quantities of urates. There is no sugar or albumin; specific gravity 1015. After one month's treatment by tissue lavage, dietetic, manual and mechanical treatment she has gained in strength and weight. Her appetite is now excellent; she eats three good meals daily, and her color is greatly improved. During six months following the course of treatment she has gained thirty pounds in weight.

Case 16.—D. K., aged 23; two of his sisters are suffering with pulmonary tuberculosis, and three of his cousins have died of it. He began treatment Dec. 4, 1896. Works all night at in-door occupation. Weight 145 pounds; lung capacity 160 cubic inches; temperature 100; sputum contains tubercle bacilli; has had a cough for about a year which came on after taking cold. Last winter he had twenty hemorrhages; has had several since; has anorexia; bowels are regular. Physical signs show diminished respiratory murmur and increased vocal fremitus over the whole right lung, mucous râles at the base posteriorly. He coughs most on rising after sleep and the expectoration is over an ounce in quantity. There is considerable embarrassment of the breathing after exercise. Under partial treatment for two months the amount of sputum diminished to about two drachms, and though formerly it was purulent and often blood-streaked, it is now mucous and frothy and there has been no blood present since the treatment began. In spite of his night work he gained very much in strength and spirits, and there has been an improvement in the condition of the lung.

In a number of cases of typhoid fever treated during the last twelve years by this method, the disease has never been very severe and in no case has there been a fatal issue.

The same method was also followed out in all my diphtheria cases with almost uniformly good results. Local antiseptics were also carefully employed.

A large portion of the body, with the exception of the framework, the padding and the nervous mechanism, is muscle, either voluntary or involuntary, and is therefore susceptible to the means employed for strengthening muscular tissue. The respiratory organs, the heart and digestive tube, if not wholly muscle, functionate only through muscular activity.

Some of the points in this paper may differ somewhat from the views of many able writers, but we must study and reason for ourselves, forming our own conclusions and stating them clearly when possible, otherwise there would never be any advancement in medical science.

THE PRACTICE OF MEDICINE IN THE NEW ENGLAND COLONIES.

Read before the H. C. Wood Medical Society of the University of Pennsylvania, Oct. 21, 1897.

BY FRANCIS K. PACKARD, M.D.

PHILADELPHIA, PA.

I propose to glance in a cursory manner at a few of the many interesting and curious facts concerning medical practice in the early days of the settlement of New England. It is a subject about which not much has been written and of which our knowledge is very scanty, compared with the thoroughness with which we know every other detail of the lives of the colonists. The truth is that our medical forefathers left but little literary material upon which to work in an investigation of their methods or experiences. But few of them devoted themselves to purely professional work, and their lives were too largely occupied with the battle against the difficulties which lay in the way of developing the new country to afford much chance for scientific or literary labor, had any of them the inclination for it.

In the records of the settlements of the New England colonists we find but few instances in which the expedition was accompanied by a regularly appointed physician or surgeon. In March, 1629, one John Pratt was appointed, by the Court of Assistants in London, as surgeon to the Salem Plantation, upon the condition, "that £40 should be allowed him, for his chest £25, and the residue for his own salary during the first year." This is all we know of poor Pratt, except his untimely end, which is recorded by Governor Winthrop in his history of New England. It appears that in 1645 he sailed for Spain in a vessel built and sailed by Thomas Hawkins of Boston, and that when in sight of the Spanish coast they struck a rock, the vessel sank and Pratt perished. Winthrop says of him: "He was above 60 years of age, an experienced surgeon, who had lived in New England many years, and was of the first church at Cambridge in Mr. Hooker's time, and had good practice and wanted nothing. But he had long been discontented because his employment was not so profitable to himself as he desired, and it is like he feared lest he should fall into want in his old age."

In April, 1629, the "Governor and Company of the Massachusetts Bay in New England" issued a general letter addressed to John Endicott, the leader of the settlers at Salem, in which they informed him that they had agreed with Lambert Wilson, chirurgion, that he should act as surgeon to the settlers, and also to the neighboring Indian tribes, for three years, and he further engaged to give a medical training to one or more of the young men of the colony.

These are the only records of the appointment of surgeons to the settlements that I have been able to find.

Our forefathers seem to have placed much confidence in the medical skill of their spiritual and secular authorities. Cotton Mather was regarded as eminent authority on medical subjects, though with a knowledge of his opinions on the subject of witchcraft, one would have been rather disinclined to trust his judgment.

There is extant a manuscript of prescriptions or formulae, which were furnished to John Winthrop, Governor of the Colony of Massachusetts Bay, by a Dr. Ed. Stafford of London, to be used in the treat-

ment of various ailments which might afflict the colonists. I have transcribed some of these as illustrative of some of the standard treatments of the day. They were found among the Winthrop Papers and were published in the "Transactions of the Massachusetts Historical Society."

The first is curious, as it brings forth Dr. Stafford's belief in the so-called doctrine of signatures. "For the yellow Jaundise or Jaunders. Boyle a quart of sweet milke, dissolve therein as much bay salt, or salpeter, as shall make it brackish in taste: and putting saffron in a fine linen clout, rubb it into ye Milke, untill ye Milke be very yellow: and give it ye patient to drinke."

It is well for the people of the Southern States, in which yellow fever is prevalent, that the second prescription I quote is not still in use. It is entitled: "My Black powder against ye plague, smallpox, purple and all sorts of feavers, Poysons: either by Way of prevention, or after Infection. In the Moneth of March take Toades, as many as you will, alive: putt them in an Earthen pott. so yt will be halfe full; Cover it with a broad tyle or Iron plate; then overwhelm the pott so yt ye bottom may be uppermost: putt charcoales round about it and over it, and in the open air, not in an house, sett it on fire and lett it burne out and extinguish of itself: When it is cold, take out the toades; and in an Iron mortar pound them very well, and searce them, then in a Crucible calcine them againe: pound and searce them againe. The first time they will be a browne powder, the next time black. Of this you may give a dragme in a Vehiculum (or drinke) Inwardly in any infection taken, and let them sweat upon it in their beddes: but lett them not cover their heads; especially in the Smallpox. For prevention half a dragme will suffice: moderate the dose according to ye strength of the partie, for I have sett downe ye greatest that is needfull. There is no danger in it. Lett them neither eat nor drinke during their sweat, except now and then a spoonfull of Warne posset-drink to wash their mouths. keep Warne and close (for a child of 5 years, 10 graynes is enough in infection, for prevention 4 or 5 graynes.) till they be pefectly well; and eate but little; and that according to rules of physicke."

But there is yet more service for his "Black powder."

"The same powder is used playster wise with Vinegar for a gangrene, or bite of ane Venomous beast, taking it likewise Inwardly: It is used likewise for all Cankers, Fistulas & old Ulcers & king's Evill, strewing it upon the sores and keeping them cleane."

The following is his prescription for "Ye Falling sicknesse: Purge first with ye extract of Hellebore (:black hellebore I meane:) and instead of St. John's Wort use pentaphyllon, (or meadow Cinquefoile:) use it as above is said of St. John's Wort, and God willing he shall be perfectly cured in short or longer tyme according as the disease hath taken root."

The list contains a recipe for "A broken bone, or a joynt dislocated, to knit them: Take ye barke of Elme, or Witch hazzle; cutt away the outward, and cutt ye Inward redd barke small, and boyle it in Water till it be thick that it Will rope: pound it very well, and lay of it hott barke and all upon ye Bone or Joynt, and tye it on: or with ye Mussilage of it, and bole Armeniack make a playster and lay it on."

The bole Armeniack of the prescription is an argillaceous earth, possessing astringent properties.

Dr. Stafford concludes with the following:

"*Nota bene*: No man can with a good Conscience take a fee or a reward before ye partie receive benefit apparent: and then he is not to demand anything, but what God shall putt into the heart of the partie to give him. And he is not to refuse anything that shall be given him, for it comes from God. A man is not to neglect that partie, to whom he hath once administered, but to visit him at least once a day, and to medle with no more than he can well attend. In so doing he shall discharge a good Conscience before God & Man. These receipts are all experimented.

ED. STAFFORD, London May 6, 1643."

The colonists welcomed the arrival of ships having surgeons aboard them and their services were eagerly sought for. Winthrop tells us that in the year 1644 "One of the deacons of Boston Church, Jacob Eliott, (a man of very sincere heart, and an humble frame of spirit,) had a daughter of eight years of age, who being playing with other children about a cart, the hinder end thereof fell upon the child's head and drove a piece of the skull before it into the brain, so as the brains came out, and seven surgeons, (some of the country, very experienced men, and others of the ships which rode in the harbour) being called together for advice etc. did all conclude that it was the brains (being about half a spoonful at one time and more at other times,) and that there was no hope of the child's life, except the piece of skull could be drawn out. But one of the ruling elders of the Church an experienced and very skilful surgeon, liked not to take that course but applied only plasters to it, and withal earnest prayers were made by the church to the Lord for it, and in six weeks it pleased God that the piece of skull consumed, and so came forth, and the child recovered perfectly, nor did it lose the senses at any time."

The Puritans, as is well known, had the most intense belief in the efficacy of prayer, as is evinced in the foregoing anecdote and in the following, also taken from Winthrop: "One Bumstead, a member of the church, had a child of about the same age (as the one above mentioned), that fell from a gallery in the meetinghouse about 18 feet high, and broke the arm and shoulder, (and was also committed to the Lord in the prayers of the Church, with earnest desires that the place where his people assembled to his worship might not be defiled with blood,) and it pleased the Lord also, that this child was soon perfectly recovered."

The first appearance of syphilis in the colonies was of such a curious nature that I have taken the chronicler's text verbatim. It is once more John Winthrop who narrates how this most grievous disease came amongst them. It was in the year 1646:

"There fell out also a loathsome disease at Boston, which raised a scandal upon the town and country, though without just cause. One of the town —, having gone cooper in a ship into —, at his return his wife was infected with Lues Venerea, which appeared thus: being delivered of a child and nothing then appearing, but the midwife a skilful woman, finding the body sound as any other, after her delivery she had a sore breast, whereupon divers neighbours resorting to her, some of them drew her breast, and others suffered their children to draw her, and others let her child suck them. (no such disease being suspected by any,) by occasion whereof about sixteen persons, men, women, and children, were infected,

whereby it came at length to be discovered by such in the town as had skill in physic and surgery, but there was not any in the country who had been practiced in that cure. But (see the good providence of God) at that very season there came by accident a young surgeon out of the West Indies, who had had experience of the right way of the cure of that disease. He took them in hand and through the Lord's blessing recovered them all in a short time. And it was observed that although many did eat and drink and lodge in bed with those who were infected and had sores, etc., yet none took it of them but by copulation or sucking. It was very doubtful how this disease came at first. The magistrates examined the husband and wife, but could find no dishonesty in either, nor any probable occasion how they should take it by any other, (and the husband was found free of it.) So as it was concluded by some, that the woman was infected by the mixture of so many spirits of men and women as drew her breast, (for thence it began). But this is a question to be decided by physicians."

In times when sickness was rife or an epidemic prevailed, days were set aside for fasting and prayer. The earliest fast day held for deliverance from sickness was kept in Massachusetts, July 3, 1644. The records simply state that "there was much sickness in the land," and do not specify for what particular disease the fast was held.

Judge Sewall in his diary records a case in which prayer seems to have been unduly exciting to the sick man. It seems it was customary, when the patient was declared to be in a dying condition, for his neighbors to gather and make long prayers at his bedside. On Sept. 20, 1690, he writes: "Mr. Moody and I went before the others came to neighbour Hurd who lay dying, where also Mr. Allen came in. Nurse Hurd told her husband who was there and what he had to say; whether he desired them to pray with him: He said with some earnestness, Hold your tongue, which was repeated three times to his wives repeated entreaties; once he said Let me alone or Be quiet (whether that made a fourth or was one of the three do not remember) and My Spirits are gon. At last Mr. Moody took him up pretty roundly and told him he might with some labour have given a pertinent answer. When we were ready to come away Mr. Moody bid him put forth a little Breath to ask prayer, and said it was the last time had to speak to him; At last ask'd him, do you desire prayer, shall I pray with you. He answered, Ay for God's sake and thank'd Mr. Moody when had done. His former carriage was very startling and amazing to us. About one at night he died. About 11 o'clock I supposed to hear neighbour Mason at prayer with him just as my wife and I were going to bed."

The Judge dabbled a good deal in medicine, and writes in his famous diary very entertainingly of some of his experiences. He strongly advocated prayer at the bedside of the sufferer, as he quaintly expresses it, to "give him a lift Heavenwards." Possibly some might question the therapeutic benefit of a dying man receiving "a lift Heavenwards."

He tells us of a Mr. Brattle he visited, and who informed the Judge that his visits were not welcome; "he plainly told me that frequent visits were prejudicial to him, it provoked him to speak more than his strength would bear, would have me come seldom."

The mortality among the early colonists of New

England was appalling. They died off like sheep. The settlement of Plymouth had been made Dec. 28, 1620, by 102 settlers, who had landed from the *Mayflower*, and during the following January and February the deaths averaged two and three a day, a very high death rate in such a small community.

Winterbotham says, "the diseases most prevalent in New England were the following: alvine fluxes, Saint Anthony's fire, asthma, atrophy, catarrh, colic; inflammatory, slow, nervous and mixed fevers; pulmonary consumption, quinsy and rheumatism."

It seems probable from contemporary accounts which have descended to us, that many deaths occurred from "galloping consumption." Influenza epidemics swept over the colonies at intervals and were attended by a remarkable fatality. Dysentery was another disease which prevailed in epidemic form throughout New England at various times. Abigail Adams, the wife of President John Adams, has left us in her "Familiar Letters" a most graphic description of the epidemic of dysentery at Braintree, Mass., in the year 1775, in which she lost many relatives and friends.

The scourge which was most dreaded, however, was smallpox. The first medical publication in the colonies was a small pamphlet, entitled "A Brief Rule to Guide the Common People of New England How to Order themselves and theirs in the Smallpox and Measles," by Dr. Thomas Thacher. It was printed in 1677. Dr. Thacher was not only renowned as a physician, but was also the first minister of the famous Old South Church in Boston, and the author of a Hebrew lexicon. His little treatise, he says, was written "not to inform the Learned Physitian that hath much more cause to understand what pertains to this disease than I, but to give some light to those that have not such advantages." He embodies, in a popular form, the current ideas of the day as to the pathology and treatment of the two diseases. He considers them conjointly, because he thinks smallpox is a disease "whose nature and cure the measles follow."

In April, 1721, Lady Mary Wortley Montague having returned to England from Turkey, introduced there the practice of inoculation for smallpox, which she had learned from the Turks. At about this time the Reverend Doctor Cotton Mather of Boston read in the "Philosophical Transactions" of the London Society an account of inoculation, written by Pylarini and Timoni, two Italians. He asked a number of the leading physicians of Boston to try it, but they all treated the proposition with ridicule, except Dr. Zabdiel Boylston, who was an intimate personal friend of Mather, and one of the leading medical men of the town. June 27, 1721, only two months later than the introduction of the practice into England, Dr. Boylston inoculated his only son, a boy of 13, and two negro servants. The attempts proved completely successful, but the practice of inoculation brought such a torrent of abuse upon the Doctor as is almost incredible. His fellow practitioners, animated partly by jealousy, partly through ignorance, united almost to a man in reprobation of the custom. He was assaulted in the streets, his house was attacked by a mob, and a bomb was thrown into the parlor in which his wife was sitting. But in spite of all opposition the method of inoculation prevailed and Dr. Boylston's triumph was soon complete. Hutchinson in his "History of Massachusetts" says, "in the year 1721, and first part

of 1722, Dr. Boylston inoculated 247 persons, and 39 were inoculated by other persons, in Boston and its vicinity. Of this number only six died and several of these were supposed to have taken the infection before inoculation. In the same period 5759 took the disease the natural way, of whom 844 died, and many of those who recovered were left with broken constitutions and disfigured countenances." What were known as "classes" were formed for the purpose of being inoculated at the same time, or as it was called, "taking the smallpox together." Many doctors established private hospitals for the inoculation of the smallpox. There were two in the immediate neighborhood of Boston, one at Point Shirley, conducted by a Dr. William Barnett, from New Jersey, the other at Castle William, in Boston Harbor, in charge of Dr. Samuel Gelston of Nantucket.

Alice Morse Earle in her amusing little book, "Customs and Fashions in Old New England," quotes an example of the ordinary method of advertisement adopted by those who managed these establishments. It is from the *Connecticut Courant* of Nov. 30, 1767: "Dr. Uriah Rogers, Jr., of Norwalk County of Fairfield takes this method to acquaint the Publick & particularly such as are desirous of taking the Small Pox by way of Inoculation, that having had Considerable Experience in that Branch of Practice and carried on the same the last season with great Success: he has lately erected a convenient Hospital for that purpose just within the Jurisdiction Line of the Province of New York about nine miles distant from N. Y. Harbour, where he intends to carry said Branch of Practice from the first of October next to the first of May next. And that all such as are disposed to favour him with their Custom may depend upon being well provided with all necessary accommodations, Provisions & the best Attendance at the moderate Expence of Four Pounds Lawful Money to Each Patient. That after the first Sett or Class he purposes to give no Occasion for waiting to go in Particular Setts but to admit Parties singly, just as it suits them. As he has another Good House provided near said Hospital, where his family are to live, and where all that come after the first Sett that go into the Hospital are to remain with his Family until they are sufficiently Prepared & Inoculated & Until it is apparent that they have taken the infection."

We are glad to relate that Dr. Boylston's rewards for his services to humanity were commensurate to his deservings. He was invited to London by the eminent Sir Hans Sloane, then physician to the Royal Family, and was honored by an invitation to inoculate the Princess Caroline. He was the first American elected a fellow of the Royal Society, and before his departure from England he published, at the request of that Society, an account of his method of practicing inoculation. He returned to Boston, enjoyed a large practice, and lived to the age of 81 in the full possession of his faculties.

Leukemia. Von Moraczewski concludes from a study of the metabolism in leukemia that it is an affection caused by diminished nutrition, essentially characterized by an insufficient disassimilation of nitrogen and phosphorus, only half of the phosphorus ingested being eliminated. Any medication that would further the metabolism and elimination would be effective, especially thyroïdin, as he has established in one case. — *Sem. Méd.*, March 26.

THE FREQUENCY OF APOPLEXY AMONG THE HIGHER CLASSES WITH SUGGESTIONS FOR ITS PREVENTION AND ESCAPE FROM FATALITY.

Presented to the Section on State Medicine at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY ELMER LEE, A.M., M.D., Ph.B.

VICE-PRESIDENT AMERICAN ACADEMY OF MEDICINE; CHAIRMAN SECTION ON STATE MEDICINE AMERICAN MEDICAL ASSOCIATION; MEMBER COMMITTEE ON REVISION OF THE UNITED STATES PHARMACOPEIA, 1890.
NEW YORK, N. Y.

It is rare that an animal dies of apoplexy, but man's days are frequently ended by this disease, coming upon him generally later than the age of 50. The contrast between the simple life of the animal and the complex one of the man is in favor of the former, so far as it relates to health. At the beginning, the young animal and the child are on the same natural footing, both are natures sweet and innocent children. Little by little the child grows away from dependence upon natural methods for its guide, substituting the artificial as life advances and ever becomes more complex. But the animal pursues an even tenor of regularity and simplicity, avoids the excesses and escapes the sad consequences of sickness, pain and premature death.

The beginning of disease is at that moment when the laws of health are first violated, and starts with infancy and childhood in the majority of cases. The great love of the parent for the offspring gradually yields to the desires of the young even though inconsistent with reason, and the gratification of them detrimental to its best present and future welfare. In the young vitality is vigorous, and in spite of bad care and over-indulgence from the well-meaning parents, it carries a large proportion of the children to adult age and beyond. The early mistake in the training of the child is the principal factor that develops into the disaster of the later years. When the child comes into the world it is ignorant of the requirements necessary for life and health, and is at the mercy of conditions beyond its power to change with reference to those who shall conduct the young life safely, or to its destruction. The laws relating to preservation of health being so little comprehended and so much neglected, affords just the state of things suited to start the beginner in life into the wrong path. The early impressions, very hard to correct later in life, added to misapprehension and error in the process of growth lay the certain foundations for disease and premature fatality.

Each nationality has its peculiar domestic customs which are transmitted to the offspring, and while some of these habits of life are innocent, many of them are directly fatal in due course. The German teaches the infant to cultivate a taste for mild liquor of the nature of wine and beer. The youth is encouraged to drink the health of the fatherland, while the adult saturates every cell and tissue in the body with a 4 per cent. solution of alcohol in malt, with supposed security and a conscious feeling of superiority to his neighbor, who tipsples with high wine and whisky. The drinker of the weaker beverage makes up in quantity what his favorite drink lacks in strength, as compared with the stronger poison of French or English friends. The result in all cases is the same, provided enough is taken and for sufficient time to destroy vital processes.

The American is the jolly associate and imitator of the convivial foreigner, freely indulging in his virtues and vices, and equal to him in the consumption of potations both mild and strong.* Familiarity with the titles and literature pertaining to alcoholic poisons, otherwise known in polite circles as "cocktails," "gin-slugs," "brandy-smashes," "Tom and Jerry," and "nightcaps," together with a very long list of fantastic names supposed to represent some peculiar virtue, forsooth, that which is good for man, is early acquired by the youth who are to constitute later the apoplectic surprises which are noted in the daily morning paper, thereby forming a morsel for comment even by those who are in the same danger but heed it not. In natural health the ideal desire is to prolong life and to walk in pleasant paths. Every one hopes to escape pain and sickness, and of the many who so desire, a few only succeed. Nature is most gentle and tender, but at the same time absolutely just, and what is suffered by man is through either folly or ignorance in his blinded eagerness to attain the satisfaction of a bauble.

So long as the grape grows and the fermented juice is brought habitually in contact with the delicate cells of a human body, and while human food is mixed with acidulated alcohol in the form of frothing beer, that man who loves the solace of these potations, and who persists in the mistake that he is stimulated and thereby refreshed, is sure to fall a fatal victim to an implacable fate which patiently waits and finally seals his doom. There are many who belong to this unfortunate class that escape apoplexy to fall earlier in life from maladies with different names, but hastened and effectual in their fatality from even that abuse of the alcoholic influence disguised under the fair apology of moderation. With an error of life of such wide and extended daily use as that of habitual drinking of liquor is there anything strange in frequent fatalities due to apoplexy?

The number of fatalities from apoplexy would be even far greater if it were not that death claims many victims of wrong living ere the course of mistakes run by weak and deluded humanity reach the apoplectic goal. This is a frequent disease among the higher classes, for it is in this class that those excesses which contribute to produce apoplexy prevail to such a degree as to keep the press supplied with obituaries of those accounted distinguished and possessed of lovable characters.

Apoplexy refers to an accident to an artery in the brain resulting in intracranial hemorrhage and pressure, causing sudden loss or diminution of sensation and power of voluntary motion. The artery ruptures through inherent weakness of the wall from previous disease. The accident is likely to be fatal, but there may be one or several strokes or ruptures at varying intervals before the patient perishes. The rupture of an intracranial artery, if near a vital nerve center, rapidly brings the life which has lived in disobedience to nature to an abrupt termination, but if the artery ruptured is somewhat remote, protracted paralysis, more or less complete, is the result.

In the light of the experiences of yesterday, it would be possible to pass the earthly days without apoplexy save in most rare instances, were the wisdom heeded which is gained by the knowledge that not one who has lived in violation to natural law has escaped a penalty exactly in proportion to his transgression. So intense is the demand for artificial stimulation when

once the natural appetite is perverted by thoughtless and innocent indulgences, later by fierce and uncontrolled intemperance in eating, drinking and sinning, in desecration of the holy temple of health, that life without these health-destroying agents seems to such characters a failure. The use of artificial and false doctrines poisons in gradual degree the whole race. The American teaches the child to prepare for fatty degeneration and its consequent choice collections of bodily afflictions, by setting examples that if followed, lead to destruction of health and loss of life.

The coffee pot is high ruler of the table and the digestion of the American family and dyspepsia prevails to the consternation of all classes and of nearly every age. The sauces and vinegars, the relishes and dressings, the salads and sweets, innocent in themselves but habitually used and abused, poison the nourishment of the body, enfeeble the circulation and weaken the vital resistance. The source of weakness as well as that of strength is regulated by the stomach, and in this organ arise the initial causes that tend to sickness and death of the body. As has been truly stated by Dr. Page of Boston, "dyspepsia is incipient consumption," thus it may be also clearly proven that from the same source arises that condition which finally ends life in the apoplectic stroke.

Too much to eat is a misfortune which has for its penalty, lack of digestion and failure to relish with a keen satisfaction the whole blessing that food is intended to confer. While to the multitude, who have insufficient food, the hardship would not be a misfortune so great if the knowledge of food and its best use was better understood and practiced. One class has too much and the other too little, and to both come disease, for in each case the natural laws of health are violated in the selection of the articles of diet, and in the preparation which civilized cookery has visited upon the members of the human family.

The almost universal custom of three meals a day finds favor among physicians and the laity alike, and even in the treatment of sickness when the system is embarrassed and struggling to overcome the obstacles forced into the unwilling human machine against the prolonged remonstrances of the digestive organs. Through excessive feeding and insufficient elimination the load ever increases, and when nature is outraged to the limit of forbearance, mild protest is succeeded by partial or complete failure to proceed further. Strange as it may be, and frequently by advice of the professional mind, the very cause of the sickness is kept up by an amount of food and of an improper character, which, while it would not amount to a surfeit to the well, does further interfere with a rapid restoration to health, and is not infrequently a direct factor in stretching a slight matter into a long sickness with recurring relapses and death.

The hard out-of-door laborer, swinging his pick and working with the shovel, is entitled to three meals a day, for they are earned and likewise needed. But this class does not constitute the apoplectic victims. This advantage, if balanced with temperance among the wage earners, would augment their happiness and add years to life and minimize their sorrows. Correct information regarding the essentials of eating and drinking for the sustenance and comfort of health has and ever will stand as the first requisite toward the prevention of sickness and apoplexy, and while it is either misunderstood or neglected, life will be robbed of its sweets to the individual, and society of lovable and useful

characters. Two moderate meals of natural and healthful food is the limit that constitutes safety to the higher classes. A morning and evening meal, with bread and fruit for the midday refreshment, with water instead of artificial drinks, would spare the waste of good friends and distinguished public men, a class generally at the mercy of fashion in eating, and to the quickening cup, with injury in the drop and fatality in excess. That person who has any symptom related to the digestive organs needs advice of the highest order and if the case progresses toward a worse condition it would be far better to seek counsel from a competent medical adviser, and never from the plausible and cunningly-worded falsehoods for whom newspaper and almanac cures are invented.

Careful experiments with different materials and weights used as clothing for the human body have established that the modern dress of heavy flannel beneath the woollens outside, with additional accessories to dress, even in cold weather, is in excess of the requirements. Then how much more unnatural is it to wear more than is needed in mild and warm climates, and such as that which includes New York and Philadelphia? By dressing the body with too much clothing, dangers to health are increased and recovery from chronic diseases retarded. As a plant would soon die without its trunk and branches freely exposed to air and light, so the human body dies gradually, though one of the causes is often overlooked or attributed to other explanations. The best light-weight underwear procurable in either silk, cotton or linen mesh for the youth and the adult, in health or sickness, is indicated both in winter and summer. Flannels are no longer recommended for scientific reasons.

Then with a correct food supply and the use of pure water for the drink, freely taken all through life, together with right use of covering for the body, which will admit of enough ventilation (seldom found among my patients and the sick generally), with sound medical counsel, places it within the reach of the average individual to avoid a premature fatality. Open air exercise is indispensable to the preservation of health and to the prevention of apoplexy. The causes of sickness and disease are the causes of apoplexy and prevention and escape from fatality means that the individual can not violate natural laws of organization and vitality, with coarse jeer at health requirements. To the hourly and daily and non-compromising demands to practice wisdom, there is no appeal, and the penalty for violations of nature's code for man's use, is paid with a forfeit of his life.

10 West Forty-ninth Street.

TYPHOID FEVER.

BY F. M. GREENE, M.D.
LEXINGTON, KY.

Numerous articles have been published in the various journals, on the antiseptic and eliminative treatment of typhoid fever, and in none, as far as observed, has the action of the remedies been discussed. The question has been asked: How do the remedies recommended in the Woodbridge method bring about a cure in this disease? We shall endeavor in a short article, to explain their action as far as known. Abundant evidence has already been produced to show that by early use of these remedies, the disease may be aborted, and many of its dangerous complications and

sequelæ prevented. The opponents of the method account for our success by charging upon us errors in diagnosis: claiming that we have been treating other diseases for typhoid fever. While we acknowledge the difficulty of diagnosing the disease in its earlier stages, and of differentiating it from malarial fever, and other affections which it sometimes closely simulates, we claim an equal right to decide the question from experience, aided by the most improved methods of diagnosis.

During the past summer and autumn, we treated a number of cases in which both the Widal serum and Ehrlich's diazo-reaction tests were used. In two of the cases, the serum test showed positive reaction and Ehrlich's test failed to produce the garnet colored ring, or pink foam. In one case the Ehrlich test gave, apparently, the characteristic ring, and the serum test, after several examinations, failed to produce immobilization, or clumping of the bacilli. The clinical symptoms in this case, during the second week, were those of typhoid fever. The temperature ranged from 104.5 in the evening, to 102 in the early morning. The patient was now put on large doses of quinin and promptly recovered. In the Widal test, we have immobilization, and distinct clumping of the typhoid bacilli, as early as the fifth day of the disease: giving an opportunity to confirm the diagnosis, and of aborting it, by commencing the treatment early. We here use the word abort in the usual sense of cutting short or stopping a disease in its ordinary course.

The subject of the therapeutic action of remedies in disease is one of great interest and sometimes very difficult of explanation. Our knowledge of their effects upon the human organism in health and disease, especially their power, when administered internally, to destroy pathogenic germs, or to neutralize toxins resulting from their presence in the blood, can be determined only by experiment. One of the triumphs of modern medicine is the discovery of the microbic origin of diseases, and our efforts henceforth must be directed to the destruction of disease-producing germs, or failing in this, to counteract or neutralize the poisonous materials resulting from their activity. There is an analogy between the action of these medicines in typhoid and that of quinin in malarial fever.

Malarial fever is caused by the presence in the blood of a hematozoon (*plasmodium malarie* of Laveran), which, having invaded the system, multiplies enormously and ultimately destroys the red corpuscles. There can be scarcely a doubt that this particular micro-organism is the cause of malarial fever. While presumptive evidence is strongly in its favor, until its life history outside the body has been fully traced and malarial fever produced by its inoculation, positive proof must be wanting. We have learned that the administration of quinin causes a disappearance of these intra-corpuscular parasites from the blood, and very soon the paroxysms peculiar to this fever cease, and health is restored. There may be difficulty in understanding how mercury and iodid of potassium cure syphilis, and yet physicians do not hesitate to resort to them in some stage of the disease. Typhoid fever is now classed among the infectious maladies and it is believed that its cause enters the system through food or water and selects a certain part of the alimentary canal for the place of its development. We are familiar with the fact, though unable to explain why the bacilli select this portion of the canal

for their nidus, no more than we can explain why the diphtheria bacilli first commence operations on the epithelial layer of the mucous membrane lining the fauces or anterior and posterior nasal cavities.

Klebs, Eberth and Koch were the first to accurately describe the micro-organisms of typhoid fever. They are represented as small bacilli with rounded ends and are anaerobic in character. They are found most abundantly in the intestinal lesions, mesenteric glands and spleen. That they are not found more frequently in the urine and the alvine discharges is doubtless owing to the imperfection of our technic in isolating them. They have been recently found in the meninges of the brain, in a case which ended fatally and in which brain symptoms were prominent early in the attack. Gaffky found the bacilli only in about half of the cases examined by him and observed that they were not scattered everywhere, but appeared usually in foci. These facts are important because it has been claimed by some, that our efforts to cure are aimed solely at rendering the alimentary canal aseptic; whereas, we claim that the remedies act first locally, by destroying the bacilli in the lumen of the bowel, and intravascularly, by inhibiting their growth in the blood and tissues of the body. We may learn more of the nature of this disease by studying its minute pathology than by any other means. Green says, "the most characteristic changes in typhoid fever take place in the solitary glands and Peyer's patches. In most cases, the process is limited to those in the ileum and cecum, and those glands are always most affected which are situated nearest the ileocecal valve. The first changes observed are hyperemia and cell infiltration of the glands; many of the cells increase considerably in size and multinucleated forms are numerous. Both Peyer's patches and the solitary glands thus become enlarged and prominent and stand up as sharply circumscribed areas, above the surface of the intestine. The surrounding mucous membrane is also exceedingly vascular and is the seat of acute general catarrh, which is most pronounced before the glands begin to swell.

"The cellular infiltration, in many parts, rapidly extends beyond the confines of the glands, into the immediately surrounding and subjacent tissues, and in some cases even into the muscular and serous coats." This stage ends the first half of the second week of the disease; it is therefore usually after this that ulceration and necrosis begin to appear and the symptoms of delirium, subsultus tendinum and failure of the secretions, indicating profound toxemia, are present.

The primary action of the bacilli is upon the mucous membrane lining the intestine in the vicinity of these glands and it is here, in the lumen of the bowel, that we may accomplish much by the proper use of antiseptics and eliminatives. When the remedies are not commenced until some time during the second week, we may still modify the disease and prevent serious complications, which now begin to appear. The complete disappearance of fever after ten days when the treatment has been commenced early, is proof sufficient that we have not only destroyed the bacilli in a great measure, but neutralized the toxins which produce such disastrous results upon the brain and nervous centers and ultimately destroy the blood itself. It is now the opinion of the profession generally that, in all infectious diseases, it is not the mere presence of the micro-organisms in the blood, but the formation of toxins, which produce such grave results.

An attack of the disease is often insidious, and it has usually progressed to the second stage before we are called. Diarrhea is so frequent an accompaniment as to be regarded as pathognomonic. It should be looked upon as an effort of nature to get rid of the disease, and it is rare that it does not appear in some of its stages. We believe that constipation, when it exists, is an indication of the mildness of the attack, and many such cases recover without medicine, by proper regulation of the diet and hygienic measures.

Proper digestion of food can not go on either in the stomach or intestines, and a fermentative process is set up by the presence of typhoid bacilli and other micro-organisms which are present. Gases are evolved and meteorism is often a distressing symptom, increasing the danger of perforation when ulceration and necrosis are present. Physicians were formerly opposed to the use of purgatives, from the idea that they produced exhaustion, and that it was necessary to husband the strength of a patient in this disease. Hypercatharsis, from the use of even mild aperients, was regarded as a warning to desist from their use, and opiates were often given to restrain diarrhea, thus favoring a condition which we now regard as most unfortunate, namely, the retention of vitiated secretions, which should be removed at the earliest possible moment. At first we were alarmed at the frequency of the actions, which sometimes amounted to five or six during twenty-four hours, but when we found that after three or four days the diarrhea lessened and the temperature began to fall, we learned to appreciate the value of this method. The loss from diarrhea was more than compensated by maintenance of the secretions and the early return of the appetite. The calomel and podophyllum given in small doses keep up a flow of bile, which is itself antiseptic and promotes the peristaltic action of the bowels. The essential oils in this prescription are eliminated through the skin and kidneys, and when given with large quantities of sterilized water, doubtless favor the escape of poisons through these channels. We believe that the treatment is very much enhanced by large and frequent draughts of cool water given during the stage of diarrhea. Thus would we advocate the Brand treatment internally, instead of externally, producing equally if not more rapid reduction of temperature.

Lastly, we consider the use of the carbonate of guaiacol in this disease, and believe that it acts as a germicide both in the lumen of the bowel and the blood and tissues of the body. It belongs to the phenol group, which occupy an important place both as germ destroyers and germ poison neutralizers. We quote from Seifert of Berlin, who has shown that during absorption "the phenols, which are not found present in the blood in their free state, combine with the albuminous substances, and especially with the most readily reactive of them, the toxic albumins which are the products of microbial life. These compounds of the tox-albumins with the phenols are probably non-toxic. They rapidly undergo oxidation in the system and appear in the urine as ethereal sulphates. To this group belong cresol, naphthol, thymol, creosote, guaiacol and others. As a class they are too irritant and caustic to be given alone. The guaiacol, when combined with carbonic acid, has proven to be non-irritant and decidedly antiseptic. During absorption it is decomposed into its constituents, pure guaiacol and creosote. The decomposition takes place so slowly and the quantity of each eliminated so minute that it

loses its irritative effect and is germicidal." In experiments upon dogs and other animals Hoelscher found that it passed the gauntlet of the gastric juice unaltered, and eliminated its effective elements in the intestine where they are most needed. Whether or not the theory be true, we are most interested in the wonderful results which follow their administration. In all cases the gastro-intestinal canal is speedily improved, the tongue becomes moist, appetite returns, the thin stools become consistent and more natural, giving off the odor of guaiacol. The odor of creosote in the urine is evidence that it enters the circulation and is eliminated through the kidneys. We have frequently observed a dark color of the urine, as from the administration of the remedy in the ordinary way.

As regards the mode of administration of the Woodbridge remedies, we do not think it essential to give them as frequently as recommended by the author. We have found them equally effective given in larger doses and at longer intervals. The somewhat pungent and disagreeable taste of the tablets may be obviated by enclosing them in capsules and giving them every half hour or hour, being careful to administer a given quantity in twenty-four hours. It is important that the patient be encouraged to drink large draughts of sterilized water. There are doubtless other intestinal antiseptics which have proven of great value in this disease. The sulpho-carbolate of zinc has some reputation, as has also betanaphthol bismuth. In the treatment of the disease in children we have found the latter to be very effective as an intestinal disinfectant, but we have not been able to abort the disease with it.

It is remarkable that until Woodbridge called attention several years ago to the antiseptic treatment, comparatively little was known or said of intestinal antiseptics. Since publishing his cases and making the announcement that he could abort the disease numerous articles have appeared advocating the use of certain remedies for this purpose. Many have advocated a treatment which they have called their own, selecting certain remedies taken from the Woodbridge formula. One selects thymol, another guaiacol, others calomel and eucalyptol, rejecting the formula as a whole.

In regard to the method we add the following concerning patients in whom the disease has been aborted and who have apparently entered upon a favorable convalescence:

After the temperature has been reduced to normal the diet and exercise should be carefully looked after for some time, and the carbonate of guaiacol continued for at least two weeks, given at longer intervals. This is especially true of cases to which we have been called at the close of the second, or beginning of the third week. There are no means by which we can positively ascertain the condition of the bowels as to ulceration or necrosis at this time. It may exist and silently go on even after convalescence has been established, and errors in diet or exercise may be the cause of relapse even when we have supposed the patient to be out of danger. The history of the following case will demonstrate the importance of these measures.

October 9 I was called in consultation to Denver Wilson, who resided two miles in the country. So far as could be ascertained, the patient had entered upon the third week of the attack. It was regarded as a typical case, the Widal test having shown positive reaction. The patient was removed in an ambulance to the Protestant Infirmary, and immediately put upon

the Woodbridge treatment. On the second day of the treatment there was an alarming hemorrhage from the bowels. Notwithstanding this, on the tenth day of treatment the temperature reached normal, and eight days afterward the patient returned home. All medicine was withdrawn and he was allowed to exercise and indulge his appetite *ad libitum*. Ten days afterward his physician was recalled and the soft capsules were resumed. Five days later we saw him again in consultation, and found him with his knees drawn up, abdomen greatly distended and suffering great pain. The patient expired the day following, doubtless from perforation, and an autopsy could not be obtained. Here was a case in which the patient was allowed to leave the hospital too soon and lost his life from imprudence. We think it fair to report all cases, successful or unsuccessful, and we ascribe failure in this case to improper management. We should therefore be exceedingly careful of the diet, even in apparently mild attacks of this disease, for ulceration may already exist when we commence treatment.

In recapitulation we recommend that the treatment be commenced as early as the diagnosis can be made, and persistently carried out until the temperature becomes normal. A careful supervision of both diet and exercise is important to insure our patient against relapse. We have observed under it diminished mortality. It is a treatment pleasant to physician, attendant and patient. It produces early disinfection of the intestine at the seat of the disease, and prevents serious complications. Baths are unnecessary except so far as surface bathing may contribute to comfort and cleanliness. Antipyretics and opiates are dispensed with. There is a quick return of appetite and rapid convalescence.

THE EFFECT OF X-RAYS IN OPHTHALMOLOGY.

Presented at the Fourth Annual Meeting of the American Academy of
Railway Surgeons, at Chicago, Ill., Oct. 6-8, 1897.

BY A. G. THOMSON, M.D.

ASSISTANT OCULIST, PENNSYLVANIA RAILROAD,
PHILADELPHIA, PA.

In December, 1895, Professor Röntgen gave to the world his great discovery that an invisible ray, now known as the X-ray, produced by sending a current of electricity through a vacuum tube, had the power of penetrating solid and opaque materials and leaving its impress on a sensitive plate. Aside from its great scientific value, this event marks an epoch in the history of medicine comparable to such discoveries as anesthesia and of antisepsis. Although there are experiments being made throughout the world and apparatus being perfected in every way, the new force, so far as its scientific or practical value is concerned, may be considered in its infancy and, as in the case of the discovery of ether and antisepsis, it has so far given its greatest aid to surgery, yet I am sure it will only be a question of time when, as we gain further knowledge of its power and effect further improvement in the apparatus used, we shall see that it will give equally valuable aid in medicine in determining the diagnosis of obscure pathologic conditions. The practical utility of this wonderful force was first demonstrated in surgery. Experiments were concurrently being made in all branches of medicine, and ophthalmologists especially watched the early developments with great interest.

As nobody knew the extent of the new, wonderful force, as with all unknown things, there was a vast field for speculation. Many of the enthusiasts claimed, and the claim was taken up by the newspapers of the country, that the new discovery would confer upon suffering humanity one of the greatest boons conceivable; it would give to the thousands of inmates in blind asylums vision to their sightless eyes. On the other hand, from a diagnostic point of view, for which we had hoped so much, we experienced immediate disappointment. All experiments showed that owing to the unfortunate position of the eyeball, surrounded by the bony walls of the skull, which were at that time thought impenetrable to the rays, the value of the X-ray in determining the presence or in locating foreign bodies in the eye, was practically negative. As regards the hope of producing vision in the blind, these experiments, so far, have shown that for any practical benefits the X-ray is useless. Dr. Brandt¹ stated, at an early date, that by removing the lens, the retina becomes sensitive to the X-rays. This was immediately contradicted by Bullo², who showed that the lens was also transparent as other neighboring tissues of the eye, the difference being due to their densities.

Experiments made by Dr. Hansell and Dr. Max Stern,³ at the Philadelphia Polyclinic, on patients with defective vision, as leucoma of the cornea, capsular and lenticular cataract, central scotoma, due to a large patch of central retinal choroiditis and atrophy of the optic nerve, showed that patients were unable to see any more clearly through the fluoroscope than before the production of the rays. This is confirmed by the report by Dr. Wilkerson of the California School of the Blind. He selected six patients for testing, one with destruction of the anterior portion of the eye from an old traumatism, one with complicated congenital cataract, one with partial phthisis bulbi from ophthalmia neonatorum and three with optic nerve atrophy. In none of these cases did the rays assist the vision in the slightest degree.

Boch⁴ suggests that persons blind from the loss of transparency of the media might be able to read letters painted on a card, varnished and dusted with a powdered metal, if these were subjected to the action of the X-rays. This is impracticable unless a fluoroscope or some other fluorescing screens, by which the shadows are rendered visible, be placed back of the opaque lens or cornea. Otherwise the source of illumination is no more available than before. All these experiments, I think, show conclusively that the X-ray, as it is known today, will be of no practical value to the blind; and this would seem also theoretically correct, as we know our retinas are only able to perceive a very small portion of the spectrum, namely, (1/20) that portion where the vibrations in the ether extend from four hundred million millions to eight hundred million millions of light. Vibrations of lesser frequency, although not seen, are demonstrated by certain instruments of precision, while vibrations above this number are known as the ultra-violet rays, invisible to the eye but demonstrated by a photographic plate. Now, as the rays are emitted from the tube at a very high rate of vibration, they may be conceived as analogous to the ultra-violet rays which are not

⁴ Minor abelin, February, 1897.

perceived by our retinas, and no matter how much they are capable of penetrating obstacles to vision, they could not make the blind see when they are invisible to the normal retina.

As time progresses and as one series of experiments after another confirm the want of value of the ray in helping the blind, we are agreeably surprised to see the advances made in the other direction, from a diagnostic standpoint, which at first thought appeared so discouraging.

Among the most serious complications in the practice of ophthalmology and one that always gives the surgeon the greatest anxiety, is the severe traumatism of the eyeball produced by a foreign agent, causing the coats of the eye to be penetrated, and where the presence or absence of a foreign body in the eye is not known. The traumatism may be great enough to destroy the eyeball for all practical purposes of vision, but the anxiety of the surgeon does not end here, for if a foreign body remains within the eye there is always the danger of the dreaded sequelæ of sympathetic ophthalmia.

In the majority of cases of this kind, we are able to satisfy our minds as to the presence or absence of a foreign body by the history of the case, subjective symptoms and theoretic considerations leading us to a positive conclusion; but there are many times when owing to the obscure history, lesions of transparency and great destruction of the eyeball, our previously known methods of diagnosis are not available. That a positive means of determining the presence or absence of a foreign body would be of the greatest benefit in such cases is unquestionable, and I thoroughly believe we have attained the ability of not only determining the presence of the body, but exactly locating it in the eye by means of the X-rays. This does not pertain to particles smaller than the one thirty-second of an inch. The experiments at first were discouraging, and this was most probably due to the incomplete apparatus. Dariex⁵ conceived that the low degree of permeability of the eye by the X-rays would undoubtedly be ineffectual in producing a radiograph. By others who worked with tubes of low penetrating power it was found that the eye, surrounded as it was by the bony walls of the skull, would be an insurmountable obstacle to the production of a radiograph. Van Duyse⁶ stated that the anterior portion may be radiographed and suggests the procedure of injecting a salt solution under Tenon's capsule to make the eye protrude. Lewkowitz⁷ showed that he was able to make a radiograph of the lids and summit of the cornea and to determine, by an elaborate method of figuring, the position of a gilt spangle placed in the conjunctival sac.

Harnisch⁸ says, as the eyeball is almost entirely surrounded by bone, which is practically impenetrable to the rays, we could only hope to discover a foreign body as far back as the ciliary region or, in particularly prominent eyes, a trifle further.

The first cases reported that were of any practical diagnostic value were by Williams⁹ and Clarke.¹⁰ Both these gentlemen, by their results, show that the ray will penetrate the bones of the skull and, if a foreign body is in the eye, it will throw a shadow on the plate

dense enough to be seen. Williams placed his patient on a table, with the cheek of the injured side resting on the sensitive plate, and allowed the rays to pass through the nasal bones and through the external wall of the orbit; while Clarke inserted a sensitized film into the nose and placed the tube to the outside of the temple. The reports of this case were followed during the next fall and winter by those of Hansell, De Schweinitz and Oram Ring,¹¹ assisted by Max J. Stern, who bandaged the plate to the side of the temple. Friedenburg¹² allowed the rays to be passed from behind the head and to strike a small sensitized plate which was cut to fit into the margins of the orbit. In all these cases the foreign body was successfully removed from the eye. These cases are exceedingly interesting, as they show a decided step in advance. They not only demonstrate that the bones of the skull can be penetrated by the ray, but the whole extent of the eyeball can be radiographed, although they all fail in giving us an accurate means of locating the position of the foreign body.

The method of not only showing the presence of a foreign body, but at the same time definitely localizing its position in the eyeball, was shown by the case recorded by Dr. Oliver,¹³ assisted by Dr. Leonard, and by Dr. William Thomson,¹⁴ assisted by Dr. William Sweet of Philadelphia. Dr. Oliver's plan is opposed to that brought forward by Exner,¹⁵ in the fact that the base line for triangulation is made anterior to the cranial shadow, and the exposures are repeated sufficiently often at fixed distances and set situations so as to give a multiple series of relational sides and angles from which the exact position of a foreign body can be accurately determined. This is a very good method and has been successful in several cases, by Dr. Oliver, although not as clear and practical for the surgeon as Dr. Sweet's method.

As I have had the advantage of personally studying the case reported by Dr. William Thomson, from entrance to leaving the hospital, and also of using the method devised by Dr. Sweet in localizing the foreign body in cases of my own up to this time I think that it is the most successful method known to insure the required degree of accuracy. The details of the case can be seen in the report of the proceedings of the American Ophthalmological Society, but it is sufficient to say here that the patient was struck in the eye by a piece of steel, some eight months before presenting himself to the hospital with an exceedingly painful eyeball. The wound of entrance was plainly visible to the outside of the cornea, and an ophthalmoscopic examination showed a dense band of lymph extending from the wound of entrance to the retina, slightly external to the disc. The important diagnostic point to determine in this case was whether the steel was present in the eyeball or had penetrated and lodged in the orbit, in a benign position.

The case was radiographed by a series of pictures, each one of which showed the exact position of the foreign body. Dr. William Thomson operated, making an incision in the sclerotic and inserting a magnet, but without any result. However, having great confidence in the method, he picked up the band of cicatricial lymph with a strabismus hook, following it to its final insertion, the retina, excised it and, to his

great pleasure, found the foreign body in it at the exact position as demonstrated by the radiograph. The magnet was not successful, as the steel would not attach itself owing to its partial covering of lymph.

The other point illustrated by this case is that it showed accurately the foreign body, inside the eye instead of the orbit. I had an opportunity of seeing a case a short time ago where the eye was enucleated for a supposed foreign body. After enucleation a piece of steel was found to be lodged in the orbit, having completely penetrated the eye. An X-ray picture would undoubtedly have demonstrated this and saved the patient a serious operation and allowed him to retain the eyeball without danger. The case of Dr. Thomson not only shows the X-ray as an important means of diagnosis in these cases but also as a great help to the operator in removing the foreign body after its exact localization.

Another case which has come under my care recently, although too early to state positive results, will help to show the advantage of the X-ray in diagnosis, in a negative way, by excluding the presence of a foreign body. A man some seven weeks ago was struck in the left eye by a small piece of flying steel from a rivet. He immediately went to a hospital in New York, and was told by the surgeon that he thought the steel to be in eye, but preferred treating him conservatively for a few days. After a treatment of a week, as a traumatic cataract was probably forming, preventing observation of the interior of the eye, and symptoms increasing in severity he advised the removal of the ball. The man declined and consulted another surgeon with the same result. He presented himself before me with the following appearance: The eye slightly red, cornea clear, linear scar three millimeters, in the upper and inner periphery of the cornea, also wound of the iris immediately back of the wound of the cornea, this having the appearance of being dragged in as if it had been punctured, and a small synechia of the pupillary margin, dense, traumatic cataract, ball painful, fields good. I had the eye radiographed and six plates taken on the first day. These showed no signs of foreign body, but owing to the great heat of the weather, the developing was unsatisfactory. Thinking heat might have affected the plates, another trial was made the next day, and this time eight plates were taken. These were all good radiographs but no sign of the foreign body was visible. I therefore decided to be governed by the radiograph in the treatment of the case, and thereafter regarded it as punctured wound without the presence of a foreign body. As the lens became somewhat swollen I did a cataract extraction combined with an iridectomy, incising the iris at the point of injury, thinking I might find the foreign body at the lens or iris. This also proved fruitless. The case recovered from the operation and is doing exceedingly well, and I firmly believe, although too early to state positively that as there is no foreign body present in the eye, the man will retain not only his eye, but his vision.

Ophthalmology is undoubtedly indebted to the X-ray, as it has added another accurate method in diagnosis of the injuries complicated by presence of foreign bodies.

As regards the deleterious effects of the X-ray, they are small in comparison to the great benefits derived. I have seen several instances of the hair falling out and slight dermatitis, but this is always due to the fact of the vacuum running down and the rays not

penetrating, and to long exposures. I have never seen any serious damage to the eye.

[Dr. Thomson then showed the apparatus and demonstrated Dr. Sweet's method of localizing from the charts made in the case of Dr. William Thomson. The following description being given by Dr. Thomson from "Transactions of the Ophthalmological Society" for 1897:]

For this purpose an indicating apparatus is used, carrying two steel rods, each with a rounded end. The indicators may be supported by a head band, and the plate held to the side of the head by an ordinary bandage. The balls of the indicator are at a known distance apart, one pointing to the center of the cornea, and at a known distance from the eyeball, while the other is parallel to the first, toward the external canthus. The visual line is parallel to the indicators and to the plate. The balls should also be perpendicular to the plate.

FIG. 1.—Diagrammatic circles of the eye upon which the measurements are made to show location of foreign body. Upper circle horizontal section; lower circle vertical section of eyeball.

In making the negatives the tube is in front, about thirteen inches from the plate, and at an angle of from 15 to 40 degrees, with a vertical plane passing through the apex of each cornea. The plate is at the opposite side of the head, and the rays pass through the eyeball and the external orbital wall before reaching the sensitive film. Two exposures are made, one with the tube in a horizontal plane, or nearly so, with the two indicators, and the second at any distance below. The angle of the tube below the horizontal is unimportant, so long as the two exposures give different relations of the indicators on the negatives.

In determining the position of the foreign body in the eye, two circles, twenty-four millimeters in diameter, equivalent to the size of the globe, are drawn upon paper. One circle represents a horizontal section of the eyeball, and the other a vertical section. Upon the vertical section a spot (A) is made at the center of the circle, indicating the position of the central indicator of the apparatus. The distance between the two indicators is measured toward the temporal side, and a spot (B) made to show the position of the external indicator.

On the circle representing a horizontal section of the eyeball;

a spot (A) is made anterior to the center of the cornea, and at the same distance that the center indicator was from the eye when the radiograph was made. Another spot (B) to the temporal side, measured by the distance between the two balls of the apparatus, marks the situation of the external indicator. Taking the first negative, with the tube nearly horizontal to the two indicators, we measure the distance of the foreign body below to the two balls of the apparatus. These measurements (B to D and A to C) are indicated on the circle representing the vertical section of the eye, and a line is drawn

FIG. 2.—Outline drawing of negative made with tube nearly horizontal.

through the points (C, D). At some point along this line is situated the foreign body. From the second negative (Fig. 3), made with the tube below the plane of the two indicators, the measurement is taken of the distance (A, E). The shadow of the foreign body is below the center indicator, and this point (E) is indicated on the first circle. The distance the foreign body is above the external indicator (B, F) is measured, and the point indicated on the circle at (F). Where a line drawn

FIG. 3.—Outline drawing of negative made with tube below the plane of the two indicators.

through these two points crosses the line of measurements made from the first plate is the situation of the foreign body, as respects its horizontal and vertical position in the eyeball.

To determine the distance of the foreign body behind the apex of the cornea, the negative made with the tube nearly horizontal is taken, and a measurement made of the distance the shadow of the center ball is posterior that of the external ball

(B, H). The distance is entered directly above the external ball on the diagram representing the horizontal section of the eye. From this point (H) a line is drawn through the ball (A) of the center indicator, which indicates the direction of the rays from the tube when the exposure was made. Taking the negative again, we measure the distance that the shadow of the foreign body is back that of the external indicator. This distance (B, J) is marked perpendicularly to the spot representing the ball of the external indicator on the diagram, and a line is drawn parallel to the direction of the rays from the tube (A, H). Where this line cuts a line perpendicular to the position of the foreign body shown on the vertical section of the eyeball is the distance the foreign body is behind the anterior portion of the cornea.

DISCUSSION.

Dr. D. C. BRYANT of Omaha—On account of the location of the eye within its bony cavity, it is difficult to find a foreign body with the X-ray or anything else in many instances. It is exceedingly difficult to locate the exact position of the foreign body. The use of the X-ray, so far as the eye is concerned, will always be somewhat limited in those few cases that we need help. If in a few cases it does help us to locate foreign bodies, or to prove that there is or is not a foreign body in the eye, it will be of great advantage. Outside of the eyeball itself, in the orbital cavity where we have larger foreign bodies, we know it is of great value.

Dr. ARTHUR D. BEVAN of Chicago—I imagine that this method of locating a foreign body in the eyeball might be enlarged and applied to the location of foreign bodies anywhere in the orbit, and I think it is very valuable because of a recent experience which I had in removing a bullet from the orbit, which I reported six months ago to the Chicago Medical Society. In this case a thirty-eight-caliber bullet struck the temporal bone. Probing could not locate it. There were no cranial symptoms. A blood clot, evidently in the orbit, protruded the eye. There was complete blindness for some days in the eye of that side. Within a couple of weeks the eyesight began to return. I had an X-ray picture taken and it located the bullet from one plane, but it was impossible to obtain good X-ray pictures at right angles in order to locate exactly its position. However, I determined from an analysis of the data at hand, with the X-ray picture, that the eye had been blind for some days afterward and pushed out of the orbit, and that the bullet must be somewhere in the orbit behind the eyeball. With that conclusion I operated and removed the bullet, but it took me an hour and a half. I had the general location of the bullet, in one plane, sufficiently accurate in my mind, but I was certainly three-fourths of an inch off in my position in the other plane, and in operating in the posterior portion of the orbit, in the position of the nerves and optic artery, I found it was slow work. I feel satisfied that the work could have been much simplified by an apparatus such as Dr. Thomson describes, and I can readily understand its great value.

As to the statement made in the paper that the disadvantages of the X-ray, using it in a wide sense, are very small and do not at all weigh against the advantages; there are disadvantages in the X-ray that we, in Chicago, are very familiar with, and I think from the reports of cases tabulated and published in the *Johns Hopkins Bulletin*, in regard to the injurious effects of the X-ray, should be very generally known.

I know of some cases in which great injury has been done by the X-ray. We are all familiar with the dermatitis which follows the use of the X-ray. I have seen two cases in which this effect has been extreme, followed by total destruction of skin, the superficial and deep fascia, and the existence of an ulcer for months after the use of the ray. I have also seen total destruction of the eye from the use of the ray and absolute loss of the ear from it. These are points which we should keep prominently in mind.

At the meeting of the American Surgical Association, held in Washington this year, Dr. White of Philadelphia read a paper on the same subject which seemed to belittle the possi-

bilities of doing damage with the X-ray. I think we should all be very cautious of this. These serious effects are not so apt to occur now as they did heretofore, because the exposures are much shorter, and serious damage rarely follows exposures of fifteen or twenty minutes. So much is thought of the injurious effects following the X-ray, in Chicago at least, that the majority of men do not, themselves, take X-ray pictures. They throw the responsibility on the photographer, so much so that one whom I know, practically compels patients to sign a contract to assume all responsibility of injury when he takes an X-ray picture. I feel quite positive that the days of serious dermatitis and injury from the X-ray are numbered, because it is better understood and the exposures are shorter. But these injurious effects should be kept in mind and be widely known. They should be known to the patient who undergoes the X-ray exposure. We have no right to expose a patient without informing him of the possibilities. It should be done in order to protect surgeons from malpractice suits, and the photographer should be cautioned to exercise great care in the use of the ray.

Dr. R. HARVEY REED of Columbus, Ohio—I think the idea of using "triangulation" for the purpose of locating an object is a very valuable one, and it will undoubtedly aid us in locating bodies in the eye as well as in other parts of the body. But there is one point I will speak of, and that is the possibility of damages accruing from making an operation when the X-ray fails to locate what the surgeon is looking for. Here is a medico-legal point which is of no small importance, because, if the radiographist says that a foreign body of some kind is located thus and so and advises me to make an operation for its removal, and I make the operation and fail to find the foreign body, supposing it did not exist, then where would I stand from a medico-legal point of view? In the use of the fluoroscope and the X-ray in the bullet case which I reported this afternoon, the track of the spot was located nearly above the ear and a little above and back of the eye, and the radiographist, although not certain that was the point at which the bullet was located, felt quite sure that was the point at which we would find the bullet. I was not convinced and resorted to the ordinary methods that I would have used had I not had a radiograph taken, and the consequence was I trephined over the point of entrance and found the bullet in the skull as I had located it. Had I made the opening as indicated by the radiograph I would not have found the bullet, and the operation might have been followed by bad results. By using triangulation for the purpose of locating foreign bodies we can thus avoid, to a large extent, the possibility of making operations where no foreign body exists, or where we are mistaken as to its actual location.

Dr. S. C. BALDWIN of Salt Lake City, Utah—Reference has been made to the paper read by Dr. Willard before the AMERICAN MEDICAL ASSOCIATION, and in all of his experience the tube has been placed not closer than from twelve to fifteen inches from the body. As a result he has never seen any dermatitis, sloughing of the skin or anything of that kind. It is a point that might be considered in using the X-ray for this purpose.

Dr. JAMES BERRY of Chicago—Where crude methods have been tried in the location of foreign bodies in the body, they have not been successful in a great many instances.

The tabulation of errors by the X-ray process is valuable for us. Dr. Reed would have been in the same position if he had trephined for the bullet where the skiagrapher thought it was, as the man that cuts into a foot for a needle that is in there and does not find it. The needle is there, perhaps, but not where it is located by the X-ray process. If we report such cases it will have value in giving the process its true standing, and I think its medico-legal relations will soon be settled. I imagine that the greatest difficulty Dr. Thomson would experience in these cases is to get correct pictures. I have tried many times to get pictures of the eye, and through the nose, and have not been very successful.

Dr. THOMSON—I think our results in the use of the X-ray are largely due to the apparatus that we use. It is perfectly evident that the tubes formerly used were so small and imperfect that it was extremely difficult to take a good picture of the orbit such as I have described.

I am not sufficiently familiar with the pathologic conditions in fractures, etc., to say much about it. However, I should think that if a series of pictures were taken with a good apparatus, they would be valuable both from a diagnostic and medico-legal point of view.

I have seen cases where the hair has come out, and again where the patients have had a slight dermatitis. Some gentleman has devised a scheme which prevents dermatitis, or any deleterious effects, by allowing the X-ray to pass through a small film of gold leaf.

OPERATIVE TREATMENT OF IRREDUCIBLE DISLOCATIONS OF THE SHOULDER JOINT, RECENT OR OLD, SIMPLE OR COMPLICATED.

BY EDMOND SOUCHON, M.D.

PROFESSOR OF ANATOMY AND CLINICAL SURGERY, TULANE UNIVERSITY;
FELLOW OF THE AMERICAN SURGICAL ASSOCIATION.
NEW ORLEANS, LA.

HISTORY.

One morning in 1895, upon visiting my wards in the Charity Hospital, I found an old man with a case of irreducible dislocation of the shoulder of three months standing. He suffered much pain and was anxious for relief. I remembered having seen, during the many years of my connection with this hospital, some eight or ten cases of such irreducible dislocations. Two, who had been put through the extension and manipulation processes, had suffered fracture of the bone near the head. None of those who had resisted tractions and manipulations of all sorts, had been operated; all had been turned away to remain crippled for the remainder of their days. And yet they were under the care of such men as Stone, Richardson, Smyth, Logan, Chopin, Schuppert, all men of recognized judgment and unsurpassed daring. Later, upon writing to a member of this ASSOCIATION, who had once graced the presidential chair, for information on the subject, he answered that very few surgeons operated upon these cases and they were left to be maimed for life.

To show the unsettled condition of mind of some prominent surgeons, I will state that in a private communication from one of them, attached to one of the largest hospitals in this country, he says that the question arose as to whether operative interference should be attempted, and having called in consultation two other prominent surgeons, it was finally decided to operate.

My first impulse was to follow the tradition, but the patient complained so much that I determined to operate, if but to relieve the pain due to the pressure of the dislocated head upon the nerves and vessels. Before doing anything, I attempted to post myself on the operation, but text-books were almost mute on the subject; standard works even said nothing, or very little: special cases or monographs were not at hand and too far away to be had in time. The history of the case is given further. Once engaged in this line of thought I became intensely interested, all the more so, that another case had presented itself at the hospital in the meantime and was awaiting treatment. Upon making bibliographical researches I was quite amazed to see how much the subject had engaged the attention of a number of surgeons, and also how inconceivable it was that in spite of this, so little was to be found in text-books and others on so important and captivating a subject. The first cases are reported by Weinhold and Swanzig in 1819, and by Wattman, 1820. After an interval of nearly twenty years comes a case by Dieffenbach in 1839, and after another lapse of thirteen years, the case of Simon in 1852. The indefatigable Langenbeck then follows with three cases in succession, and Post with one in 1861. Almost every year after this at least one case is reported. In the sixties, three cases; in the seventies, twenty-two; in the eighties, forty-nine. As we draw near the present date, cases become more numerous; the year 1891 alone saw thirteen cases: 1893, eleven;

1895, seventeen. Special papers or dissertations more or less important have been written by some eight or ten surgeons. Of these the particularly important, valuable and epoch-making are those of Knapp, 1889;¹ Smital, 1890;² Delbet, 1893,³ and McBurney, 1895;^{3*} all within these late years. In this array of cases American surgeons have contributed largely. Ollier says that the first resection for irreducible dislocation was performed by Post of New York,⁴ and the second one by Warren of Baltimore.⁵

The second French Congress of Surgery put up the question of interference in irreducible dislocations: a certain number of communications were made regarding interference in dislocations of the shoulder,⁶ but they are based upon insufficient data.

FIFTY-SEVEN DIVISIONS, FORMS AND VARIETIES OF OLD IRREDUCIBLE DISLOCATIONS OF THE SHOULDER.

The subject which is now engaging our attention presents from a clinical and practical standpoint a number of forms and varieties which must be well defined at the outset. By clinical form and variety we mean a condition characterized by some feature or features bearing upon the diagnosis, prognosis, treatment and result. These various forms and varieties may be summarily stated as being: 1, recent, simple or complicated, and operated by reduction or resection; 2, old and simple, forward, downward, etc., and treated by reduction or resection through an anterior incision or an axillary or a posterior incision; or treated by subcutaneous sections (fibrous, tendinous, muscular, osseous), or by osteoclasia; 3, forms and varieties due to causes anatomic or physiologic, to causes pathologic, to complications, to recurrences; 4, to the sequels of the operation.

Guide.—Each operated case presents to study the diagnosis or kind of dislocation, its duration or time of standing, the condition of the muscles, of the limb, shoulder, arm, forearm, hand; extent of each movement without or with participation of the scapula, paralysis, paresis, atrophy, weakness, electric reactions; of the artery as revealed by the radial pulse; of the veins, by the edema of the hand or forearm; of the nerves, by anesthesia or pains; the operation performed; the difficulties and complications during the operation; complications after the operation; the results immediate, the results remote or final; the remarks and the references.

We will not mention these headings in each case, but the reader will bear in mind the order followed in describing the peculiarities.

This study rests on 157 operated cases, of which 23 are recent and 134 old cases. It is rare cases that most require collective and minute investigation since one operator has seldom the opportunity to acquire extensive personal experience and has to rely upon that of others. Hence we report herein the histories of the cases with all details of interest, which are so eagerly sought and so gratefully appreciated by operators who have a rare and difficult case to treat.

We always append the year to the name so as to identify the case throughout, specially when the name of the same operator has been repeated in two or more cases.

Incomplete data is a very serious obstacle to a thorough study.

Important rule.—No operation should be attempted before all possible means of bloodless reduction have been conscientiously applied in recent as well as in

old irreducible or unreduced dislocations. However, very sound judgment has to be exercised as to the degree of force to be used, lest more or less extensive tears take place in the muscles, vessels and nerves or fracture of bones, forcing an operation at a great disadvantage.

The word irreducible is here adhered to because it conveys the idea that all bloodless means have been attempted but in vain and that nothing remains to be done but operate. Whereas the word unreduced might lead one to think that nothing at all had been done.

IRREDUCIBLE DISLOCATIONS RECENT AND SIMPLE.

We will call recent all dislocations no older than a month; this is somewhat arbitrary but is adopted to fix a limit.

1. *Irreducible dislocations, recent, simple and forward, treated by arthrotomy and reduction through an anterior incision.* are three in number reported by Stimson 1890, Parmenter 1891,⁸ Keener 1894.⁹

The duration of the dislocation was two days (Stimson), one week (Parmenter), four hours (Keener). In Stimson's case, the head was arrested by the tendon of the subscapular, which was sectioned and reduction easily effected; in Parmenter's case the tendon of the two spinous and of the subscapular muscles had to be divided and even then the reduction was difficult. Complications following the operation were totally absent in the three cases. All report primary union. The remote results are fair only in Parmenter's case, good in Stimson's and very good in Keener's. Therefore the early interference in these cases is favorable.

2. *Irreducible dislocation, recent, simple and forward, treated by resection through an anterior incision.* is represented by the single case of Wyeth 1895.¹⁰ It was twelve days old. Through an anterior incision, McBurney's hooks were inserted in three different places, but without avail and the head had to be resected. Severe shock followed and death resulted in twelve hours. As far as this single case is concerned it seems to show that resection is a more secure operation.

3. *Irreducible dislocation, recent, complicated with fracture and having been subjected to violent efforts at reduction* should not be operated on until the inflammation has abated, lest we encounter bruised and lacerated tissues which would more easily suppurate and thus give rise to a double compound condition, the open joints and the focus of the fracture.

4. *Irreducible dislocation, complicated with fracture below the head and forward, treated by an anterior incision with arthrotomy and reduction.* has been recorded by Stemen 1893, two cases;^{11 12} Porter (C. B.) two cases 1893 and 1896;^{13 14} McBurney 1895 and 1896;^{15 16} Berger 1896;¹⁷ Bull 1897.¹⁸

The duration was a few hours in one of Stemen's cases, nine days and one month in Porter's two cases; two weeks in McBurney's, sixteen days in Berger's, two days in Bull's. All used an anterior incision down to the bone. Stemen seized the end of the upper fragment with lion jawed forceps. In one case Porter drilled a hole in the head of the bone and inserted a hook. McBurney inserted a peculiar one of his invention; Berger seized the tuberosities with strong forceps (Xavier Farebenf), Bull tried McBurney's hook but had to pry the head into place with a periosteal retractor. No difficulties nor complications were experienced by Stemen, McBurney and Bull, but Berger states that he had to pull with great force

to disengage the head and bring it in the glenoid cavity; he mentions no injury to the tuberosities. Porter (No. 2) removed a number of fragments and stitched the head to the shaft. McBurney stitched the head to the tuberosity and shaft with catgut. No sutures through the bones were thought necessary in the other cases to insure proper adjustment of the fragments. No complication followed the operation and primary union took place, except perhaps in Berger's case where it is not stated, and in Porter (No. 2) where long suppuration followed and the head had to be removed. The remote result was only fair in Berger's case, good in Stemen's and Bull's, very good in Porter's No. 1, and in McBurney's; improved only in Porter's No. 2. The conclusion is that various instruments therefore can be used, carefully, to replace the head in obstinate cases, and that suturing may give a good result.

5. *Irreducible dislocation, recent and forward, complicated with fracture below the head, treated by resection*, is recorded only once by Tripear.¹⁹ It was thirteen days old; there was a comminuted fracture with pieces wedged in between the humerus and the glenoid cavity together with a fracture of the surgical neck. A serious complication was an aortic insufficiency with a hypertrophied heart. The union was secondary and the convalescence delayed and interfered with by the circulatory disturbances just mentioned. The final result was only fair.

6. *Irreducible dislocation, recent, complicated with fractures of the head with dislocation of the head in the axilla treated by reduction*, is represented by the unique case of Wölfler,²⁰ who pegged the head back and reduced it. No difficulties or complications are reported; no complication is noted as following the operation; the union was primary and the final result good. McCormac says that Helferiot also used the peg, but he gives no reference. It is noticeable that the head loose in the axilla has never been known to become necrotic (McCormac). The danger of such procedures is the consequent callus causing more or less limitation of movement if it be large and irregular.

7. *Irreducible dislocations, recent, complicated with fracture of the head, with dislocation of the head in axilla and treated by resection or removal*, are comparatively numerous, reported by Morton, 1884²¹ (T. G.); Manclair, 1889;²² Croft, 1891;²³ Poirier and Manclair, 1892;²⁴ Clutton, 1892;²⁵ Monks, 1895;²⁶ and McGraw, 1896.²⁷ The duration or standing of the injury is laid down as recent (Morton and Croft), eight days (Clutton), four hours (Monks), four weeks (Poirier and McGraw). All were operated by an axillary incision and by resection, *i. e.*, by removal of the dislocated head, all without serious difficulty. McGraw notes also a second fracture below the tuberosities. No complications followed the operation and primary union is noted in all the cases. All recovered with a final result good in Croft's, Clutton's, Poirier and McGraw's; Monks' case died, apparently of shock. Clinical experience therefore is in favor of the removal of the head in such cases.

8. *A case of irreducible dislocation, recent and backward (subspinous), complicated with fracture of the head*, is reported by Brinton.^{27*} The head was resected, *i. e.*, removed and the extremity of the fragment smoothed and brought into the socket. The wound suppurated, but the final result was satisfactory.

Remarks.—Stimson condemns open arthrotomy, when a recent fracture is present.²⁸

He also condemns primary excision of upper fragment; he says, wait until inflammatory and reparative processes have ceased, then remove the upper fragment if it seems advisable (Stimson, p. 257). In view of the results above recorded a more modern opinion was solicited from so high an authority. The courteous answer is as follows:

"The opinion expressed on page 257 is I still think sound, although added experience and improved technique have diminished the risk incurred by operating under the conditions mentioned. I still think that arthrotomy through torn tissues infiltrated with blood and inflammatory exudates is hazardous because of the chance of suppuration, and I think the special risk begins and increases after the first or second day. I do not condemn the early operation or primary excision when indicated; I have practiced both and with success, but I here warn against the risks of what may be called the tardy early operation cutting into swollen discolored tissues about severe injuries after the second day. The statement first referred to needs now to be supplemented by mention of McBurney's brilliant method of reducing the dislocated upper fragment, in which the incision does not open the joint or pass through torn tissues."²⁹

The following remarks from McBurney's valuable contribution are worthy of note. Surgeons have been agreed that whenever fracture and dislocation of the same bone has occurred the dislocation should first be reduced if possible.³⁰

We must again recall the important rule not to operate before trying to reduce, and the following remarks of McBurney are most timely. When the fracture is near the head the heel process is useless and dangerous.³¹

Manipulations by pressure with the thumbs and fingers on the head are most infrequently successful.³² It succeeded in thirty-six out of eighty cases.³³

Failing to reduce, some surgeons have treated the fracture until firm union had taken place, and using the repaired shaft for extension, rotation or leverage, endeavored to reduce.³⁴ Three cases out of ten are reported as successful but not without criticisms.³⁵

Riberi practiced passive movements to establish a false joint at the point of fracture.³⁶ It may succeed where the fracture is high up and the lower fragment has been raised by muscular contraction outside the upper one and near to the glenoid cavity.³⁷ Seven cases are reported as successful but there are no details as regards movements, pain or disability caused by the dislocated head.³⁸

Reduction by open arthrotomy and subsequent treatment of the fracture is preferable to resection of the fractured head, because it offers the prospect of a more nearly perfect final result than the other plan.³⁹ In case of reduction the bones should be sutured.⁴⁰ If union fails reaction should be made at once.⁴¹

If reasons exist for not performing the operation of open arthrotomy and reduction, the resection of the head might well be left for subsequent consideration, and then after all acute symptoms had subsided, be resorted to in case sufficient pain or disability existed to call for this secondary operation.⁴² It has occurred to me that the hooks might be useful in some cases of old dislocation of the humerus in applying counter-extension to the scapula, *i. e.*, by applying also a hook at the base of the spine of the scapula.⁴³

IRREDUCIBLE DISLOCATIONS, OLD AND SIMPLE (ONE HUNDRED AND SIXTEEN IN NUMBER).

9 and 10. *Irreducible dislocations, old, forward, treated through an anterior incision by arthrotomy and reduction, and by arthrectomy or resection.*⁴⁵—Some twenty different difficulties and complications have been mentioned by operators in dealing with those cases; capsule thick, dissection tedious, reduction difficult, excessive fibrous tissue around the head and surgical neck, head deeply seated, head adherent to ribs, extensive muscular dissections, old fractures of the tuberosities, of the glenoid cavity, of the humerus; glenoid cavity filled with remnants of the capsule and fibrous tissue, glenoid cavity readily freed or cleared; parenchymatous hemorrhage during the operation, wounds of vessels during the operation, rupture of the axillary artery in trying to reduce before and after cutting, and various other difficulties.

Some of these difficulties and complications are common to both operations or are as liable to occur in the one as in the other. They are: new capsule thick, dissection tedious, excessive fibrous tissue around surgical neck and head, head deeply seated, head adherent to ribs, old fractures of the tuberosities, glenoid cavity and humerus, glenoid cavity filled with remnants of capsule and fibrous tissue, parenchymatous hemorrhage during operation, wounds of vessels during operation and sundries.

We find the following more frequent in reductions: reduction difficult, extensive muscular incisions, glenoid cavity normal, glenoid cavity freed and cleaned; fracture of humerus in trying to reduce before or after cutting; one notes that the greater tuberosity had to be cut away in order to be able to unite the edges of the muscular and cutaneous wounds; one, that the head of the humerus was partially destroyed; another, that there was crepitation in the joint. We note as more common in the cases of resection: excessive fibrous tissue around fractures of the head or the surgical neck; hemorrhages and sundries. Although reduction difficult is naturally more frequently mentioned in cases of reduction 24 per cent., yet we find that in 10 per cent. of resected cases it was difficult to place the sectioned extremity of the humerus in or near the glenoid fossa. Excessive fibrous tissue is noted specially in 28 per cent. of resections against 15 per cent. of reductions. Hemorrhages have occurred oftener in resections, although there is no special reason to account for this; on the contrary, they should be more common in reductions since these usually require more extensive dissections. Most of the sundry difficulties and complications mentioned in connection with resection are all of such nature as to have rendered resection the only operation possible. The complications noted after the operation are, hemorrhage, gangrene of the limb, suppuration, necrosis of head and of sectioned extremity and the formation of a false joint in a case of fracture. Hemorrhages are more frequent in resections, 4 per cent. against none in reduction. Suppuration is twice as common after reduction. Necrosis of the head occurred in 16 per cent. of the cases of reduction against 2 per cent. of necrosis of the sectioned extremity of the humerus.

As to results immediate, primary union is noted in 26 per cent. of reduction and 30 per cent. of resection. Short suppuration occurred in 17 per cent. of reductions against 22 per cent. of resections. Long suppuration shows 10 per cent. in reduction and 16 per

cent. in resections. This is all the more remarkable that reductions necessitate more extensive dissection, and that the head and cartilage have often been reported as necrotic in reductions.

The results remote or final show: Death 10 per cent. in reduction and 12 per cent. in resections, the causes of the fatal result are in reductions, bronchitis, sepsis, apoplexy and tubercles in the peritoneum. In resections, sepsis, gangrene from ligation of the axillary artery, secondary hemorrhage and pneumonia. All these causes of death are preventable today except tuberculosis, apoplexy and pneumonia, which are accidental. Hemorrhage can be averted by keeping close to the bone all along, in the capsulo-periosteal sheath, using a sharp chisel and hammer against the bone throughout, actually scraping the bone of its superficial compact tissue, a sharp chisel will require less force to do effective work and is therefore less apt to slip and injure the vessels specially under the influence of the hammer strokes. The dissection should proceed from backward forward. Sepsis we understand how to prevent, but it seems that those cases call for extra care. The neglect to apply such systematic procedure as is recommended by Ollier to test the extent and strength of the various movements, renders it difficult to judge of the true benefit of the operations, and we must be contented with the results as expressed by the operators. In a number of cases the final result is not stated. Mere improvement is not so often noted in reductions 5 per cent., as in resection 28 per cent. Fair results are quoted as 16 per cent. in reduction and 6 per cent. in resections. Good results mark 5 per cent. in the cases of reduction against 42 per cent. in resections. Lastly, the results in good to very good is 3 per cent. of reduction and 87 per cent. of resection. If we consider only the cases noted as fair, good and very good we find 69 per cent. of reductions against 57 per cent. of resections, in spite of the comparatively frequent necrosis of the head in reductions. The 16 per cent. of necrosis of the head in reductions followed by resection of the head should truly be placed to the credit of resections. The figures of percentages are most likely only approximate, because in all probability all the operated cases, good and bad, specially the latter, have not been reported.

By comparing the dates we do not see that asepsis has as yet made its full impress upon either operation. We find all the cases of necrosis of the head occurring since 1887 (Blasius), when the new era is considered to have been in operation everywhere, specially under the men of mark who stand as the operators.

General and final conclusions in regard to forward dislocations. From the foregoing study we feel justified in formulating the following conclusions: The anterior incision is the best route. Reduction is the more desirable operation because it preserves the head and all the movements depending therefrom. Reduction should be done only in cases where the head and glenoid cavity are in good condition; when no extensive dissections have to be made; when it is easily effected without any great effort; when the head does not need to be trimmed or the cup to be too deeply scooped or enlarged; when the head readily remains in place but not too tightly. All this regardless of the time or standing of the dislocation. It should, however, always be attempted conscientiously, because many have resected perhaps when the dislocation could have been reduced. Disregard of these rules may result in necrosis of the head, in recurrence of

the dislocation or in ankylosis with their inevitable consequences.

Resection should be practiced in all other cases. When in doubt it is preferable to resect. How much to resect, *i. e.*, where to saw, through the anatomic neck or obliquely and downward outside the tuberosity, or horizontally on a level with the lower margin of the head, must be determined in each case; it is best to remove too much than too little.

All efforts should be made to secure aseptic results. Extra care is called for in these cases, but especially those of reduction.

Remarks.—We append here some interesting remarks on the causes of the difficulties of reduction, mostly from Delbet's paper, which was based specially on forty-four autopsies of old dislocations.

Exceptionally the fibro-cartilage of the margin of the cavity is detached, and also the periosteum, both remaining continuous with the anterior ligaments and forming a pouch under which the head is lodged; those are called subcapsulo-periosteal dislocations (Hartman and Broca). In place of the natural capsule, there is in some cases a thick fibrous mass extending from the acromion and the deltoid to the cup and to the head of the humerus; the head has truly lost its right of domicile.⁴⁶ Sometimes the remains of the old capsule becomes partly ossified⁴⁷ (*Key, Os sesamoids dans les tendons dessus épineux, dessous épineux et du petit rond. Kocher, Observation III*). The capsule, stretched over the glenoid cavity, may be found adherent to it (cases of Bourgeois, Bordet, Burekhardt, A. Cooper, Key, Demana, Hartman and Broca, Houel, Knapp, Kocher (one autopsy and two operations, *Obs. III and VII*); Lépine, Maas, Malgaigne (two cases); Pfeiffer, Quenin, Smital (two cases); Thore, Vamossy, Wattman⁴⁸). In some cases the rent in the capsule has healed so completely behind the head as to prevent reduction. The capsule was ossified in a case of Kocher (No. 3). In another the glenoid cavity was filled with a thick layer of bone.⁴⁹ It is very seldom that the cartilaginous portion of the head gives insertion to fibrous bands.⁵⁰ Usually the new ligaments or adhesions or capsule extended from the margin of the new cavity to the neck of the humerus.⁵¹ The anterior part of the neo-capsule is usually very thick, two millimeters or more, and very resistant; it is often adherent to the vessels and nerves. In one case of Lister, seven weeks old, the artery was surrounded by these fibrous bands.⁵² Often a strong fibrous band, well described by Malgaigne, extends from the inferior surface of the acromion to the head of the humerus near the greater tuberosity. This is well mentioned in the cases of Bardenheuer, Faure, Fauratier, Houel (Dupuytren Museum, 731 A), Malgaigne.⁵³ The tendon of the biceps may remain in the groove and follow the humerus. It is more or less blended with the neo-capsule and it is often difficult to dissect it. Sometimes it is adherent to the groove (Parmenter). In some cases the tendon is disinserted from the groove, glides behind the head, where it forms a tense cord in front of the glenoid cavity (Kocher, two cases, *Observations V and VI*; Gauderon, Knapp, Lépine, G. Smith, two cases; Schede).⁵⁴ In operating, take care of the long tendon of the biceps. It is said that it is never displaced from its sheath in ordinary subcoracoid dislocations of the limb.⁵⁵ The tendon of the biceps should be preserved or stitched back.

The muscles or their sheaths, or both, often undergo

sclerosis and this prevents reduction of the head, as proved by successful reduction only after the section of the muscles (Dieffenbach, Weinhold, Bardenheuer, Ollier, Kocher, Bordet, Cooper, Parmenter). The deltoid and the supra-spinous are the muscles which oppose mostly the reduction.⁵⁶ In some cases the anterior edge of the glenoid cavity forms a part of the new cavity, and this condition renders reduction illusory and probably useless. This is met with once in every five.⁵⁷ The old glenoid cavity becomes filled up by fibrous tissue.⁵⁸ The inner edge of the new cavity found on the scapula presents usually a high rough edge.⁵⁹ The head proper of the humerus may remain normal, but it is usually flattened behind where it is articular. Its front part becomes covered with more or less irregular projections or stalactites.⁶⁰ With all this it may also be very large, rendering reduction impossible. The small tuberosity is sometimes torn away by the subscapular.⁶¹ The greater tuberosity when torn away and loose from the muscle drops into the old glenoid cavity. When it still remains attached to the muscle it becomes united, but in an irregular manner, causing deformity and considerable widening of the region.⁶² In some cases the tuberosities are very much enlarged without any trace of fracture.⁶³ All those anatomic-pathologic changes occur sometimes rapidly. The adhesion of the capsule to the cup has been found after two or three months, the head flattened after one month, even twenty-three days; the muscular retraction after five weeks.⁶⁴ Usually several of the causes combine to prevent reduction or resection; it is very seldom that a single cause accounts for it.⁶⁵ What influences the results most is the degree of the lesions, the condition of the muscles, the manner in which the operation is performed in regard to asepsis, the individual predisposition; some patients manufacture fibrous tissue so rapidly that it is very difficult to prevent ankylosis, such as rheumatic patients.⁶⁶ The axillary route was advised by Langenbeck, because of the projection of the head into the axilla.⁶⁷ It allows an easy resection. But it does not permit reduction if it were possible; it does not enable to clean out the cup; the vessels and nerves are more exposed to being wounded, specially the circumflex; the upper parts of the new and of the old capsules are immovable and can not be destroyed, and as they prevent the head from bulging it renders the resection more difficult.⁶⁸ The posterior route was recommended by Charles Nélaton, but it does not allow of any access to the anterior part of the head and of the adhesions of that part.⁶⁹ The antero-external route is the one which has scored the greatest number of successes.⁷⁰ The incision of Langenbeck, acromio-humeral, is a more vertical one than the next one; it gives an easy access to the cavity, but it renders the head less accessible.⁷¹ The inter-pectoro-deltoid incision is rather farther from the cavity, but it gives a better access to the head.⁷²

The normal or good condition of the muscles of the shoulder is a circumstance which has been too little considered in regard to the probable result of a severe operation (arthrotomy or resection).⁷³ A most important point is to get primary union. Suppuration is more frequent in arthrotomy.⁷⁴ The functional result depends specially upon the after-arrangement. At first place the arm in the position which keeps best the head in the cup; next follow the instructions laid down by Ollier in his "Treatise on Resection."⁷⁵

II. Irreducible dislocation, old and forward, treated

through an axillary incision by arthrotomy and reduction, is represented by one case only, that of Kocher (No. 1), 1889.⁷⁰ The greater tubercle, which was broken off, had to be resected in order to be able to reduce; the capsule was very much thickened. There was suppuration followed by resection of the head. Seven months after the joint was almost completely ankylosed.

12. *Irreducible dislocation, old and forward, treated through an axillary incision, by resection.*—There are eight cases on record, by Langenbeck 1860,⁷¹ Lester 1873,⁷² Spieker 1876,⁷³ two cases,⁷⁴ Langenbeck again in 1877,⁷⁵ two cases,⁷⁶ Volkman 1882⁷⁷ and Nélaton in 1888.⁷⁸ In Langenbeck's of 1860 the great tuberosity had been fractured; Lister had ruptured the artery in trying to reduce before cutting; Spieker also found that the great tubercle had been broken off in his two cases. Nélaton mentions the same complication. In case number two of 1877, Langenbeck found the operation laborious because the head was more deeply seated than appeared; there was also considerable hemorrhage requiring the ligation of many vessels, probably of the subscapular, in the depth of the wound. Volkman speaks also of great difficulty; the lower tuberosity was broken, there was hemorrhage due to injury of the axillary vein by a splinter of bone; the vein was ligated. Nélaton says that the posterior portion of the articular capsule was flattened against the glenoid cavity, was thickened and did not permit itself to be sufficiently separated to allow the head to be reduced; to overcome this obstacle it would have been necessary to split the capsule transversely, but the incision having been made in the axilla, the capsule could only be reached with the tip of the finger from deep in the wound and it would have been difficult to introduce a bistoury, so resection was done. Following the operation, Lister mentions great shock; there was suppuration in Spieker's two cases, erysipelas in Langenbeck's case number two of 1877. The cases of Langenbeck 1860, and number two of 1877, and of Volkman healed primarily; Spieker number one showed short suppuration, and his case number two long suppuration. Death followed in the case of Lister in three hours, of Spieker number two from sepsis, and of Langenbeck number two 1877 from erysipelas and sepsis. The results found are therefore three deaths (Lister, Spieker number two, Langenbeck number two 1877); little improved Langenbeck 1860 and Langenbeck one 1877; improved simply in Spieker one. This route is therefore fraught with danger and should not be followed in cases of forward dislocations.

13. *Irreducible dislocations, old and forward, treated through a posterior incision by arthrotomy and reduction.*—Two cases are on record by Schonborn (No. 3),⁷⁹ 1885, Mudd 1895.⁸⁰ Repeated attempts were necessary in the case of Schonborn; the acromion process, which had been detached according to Kocher's method, was with difficulty pressed back into position by Mudd. Recurrence of the dislocation upon dressing took place in Schonborn's case. The healing of the wound was even in Schonborn's; primary union took place in Mudd's case. The results remote were good in Mudd's case; it is not mentioned in Schonborn's.

14. *Irreducible dislocations, old, simple, forward, treated by subcutaneous sections of fibrous bands, tenotomy, myotomy.*—Five cases stand on record: Weinhold-Swanzig 1819,⁸¹ Dieffenbach 1839,⁸² Simon

1852,⁸¹ Polaillon 1882,⁸² Mollière 1886.⁸³ Weinhold picked up a fold of skin, the external portion was incised transversely to the extent of half a finger's breadth from the insertion of the great pectoral, very forcible extension being kept up. While this was accomplished, wound was increased in length to the extent of nearly half a finger's breadth; immediately the humerus approached near the glenoid cavity and returned in place. The operation was simple in the case of Dieffenbach; it was done in one sitting when traction reduced the head; Simon did it in three sittings; Polaillon attempted reduction only three days after the tenotomy. There were no difficulties and complications during the operation nor after. The results remote are stated as being very good in all five cases. It is astonishing that a method so simple, so safe, and giving such perfect results, should not have been tried oftener. However, when we consider the great difficulties encountered in an open operation before the head can be reduced, when it can be, after the necessary sections have been freely done, it is really most probable that the method has been tried but has been found wanting and the failures have not been recorded. It seems best adapted to selected cases.

15. *Irreducible dislocations, old, forward, treated by osteotomy of the neck.*—We could only find one case on record by Dr. Mears.⁸⁴ It was a subcutaneous osteotomy as practiced by Mr. Adams. The operation presented no difficulty nor complication, nor were there any complications after the operation. The wound healed without suppuration; the result remote was good for a while, but later a callus formed and the result proved to be very unsatisfactory. This ought not to encourage in such an operation. The writer proposes the following operation in place of subcutaneous osteotomy or osteoclasis, in cases where there are no serious pressure symptoms and the patient is not in a condition, from age or debility, etc., to stand a long operation with possible injury to the vessels and their consequences: After exposing the bone, resect at least one inch of the shaft where it joins the head; place the resected extremity in or near the glenoid cavity and begin passive motions early. This procedure leaves the head in an abnormal position, and that is the great objection to it, but it is a more simple and quick operation than the regular one for reduction and resection when the head is firmly and extensively bound down, in the class of cases above referred to. It is sometimes difficult to decide from the description of the case if it is a downward (subglenoid, axillary) or a forward dislocation (subcoracoid, preglenoid) that is meant.

16. *Irreducible dislocations, old and downward, treated through an axillary incision.* are represented by three cases: Langenbeck 1877,⁸⁵ Patterson 1879,⁸⁶ Thomas 1885.⁸⁷ There was no special difficulty or complication, except that in the case of Thomas the operation was long and tedious, great difficulty in freeing the head; it had to be removed by slices. In this case of Thomas there was suppuration after the operation. There was primary union in all the cases except Thomas', in which the wound closed at the end of the second month. In this same case there was little improvement; in the two others the final result is not recorded. The operation should be performed but may prove not so very easy.

17. *Irreducible dislocations, old and downward, treated by osteoclasis.*⁸⁸ One case that of Desprès. It

consisted in the deliberate fracture of the neck so as to be able to bring the arm closer to the body; the forced elevation of the arm causing it to press against the acromio-coracoid vault or arch, determined the fractures; a cracking sound was heard and crepitation felt. There was no difficulty, no complication during the operation. There was formation of a callus, it was impossible to obtain a false joint, and the operation resulted in a thorough failure. This procedure should be rejected except perhaps in special cases when a more serious operation is out of the question. It is to be remembered that several cases of fracture in trying to reduce have been followed by fair results.

18. *Irreducible dislocations, old and backward, treated by resection in the adult.*—There are three cases reported by Reid 1877,⁹⁹ Adams 1888,¹⁰⁰ Brinton 1897.¹⁰¹ (The cases of Post 1881 and of A. M. Phelps 1895, are congenital and will be considered under that head.)

Reid's case was 53 years old. The age of Adams' case is not mentioned. No difficulties were mentioned. No complications after the operation are noted. The results immediate are not described. The results remote, not improved in Reid's case; fair in Adams'. Although these results are not brilliant they suffice to justify the operation.

Brinton's case was complicated with a united fracture below the tuberosity, the final result was satisfactory.

19. *Irreducible dislocations, old and simple, with a limb useful in its new position* to all intents and purposes to the patient should not be operated.

20. *Irreducible dislocations, old and congenital, operated by reduction.* are three in number, operated by Küster 1882,¹⁰² Schede (No. 3) 1892,¹⁰³ and Brown 1897.¹⁰⁴

Küster's case was 14 months old at the time of the operation. Schede's case was 8 years, but the luxation was congenital and intra-partum, as was proved by the doctor who attended the mother's confinement. Brown's child was several months old when operated. In Küster's case the head was freed, brought forward and rotated. In Schede's, the head was freed, the glenoid cavity enlarged and deepened, and the anterior part of the capsule removed; the posterior part is freed from the glenoid cavity and drawn forward so as to cover the head; dislocation reduced; the coracoid process had become more crooked and longer and bridged over the inner portion of the normal cavity in such a way as to prevent reduction; it was separated partially at its base by an osteotomy and broken so far backward that it no longer prevented reduction. The reduction is easy in Brown's case. There was fever and suppuration in Küster's case. In Schede's suppuration also and later the greater tuberosity was found to be necrotic and was removed and the healing was gradual. Brown's case healed kindly. Death resulted in Küster's case, one month after operation, in Schede's the result was good. Brown's case was much improved. In Küster's case there was also a similar dislocation on the other side, but it was not operated.

In résumé the operation should be done, as there is no other alternative but observing the rules governing reductions as set forth above.

21. *Irreducible dislocations, old and congenital, treated by resection.*—There are three cases on record, one by Post 1861,¹⁰⁵ and two cases by Phelps (A. M.) 1895.^{106, 107} Phelps mentions one case operated by

Gerster and four other operated cases, but he gives no references. All these cases are backward dislocations, subspinous. The operation performed in Post's case was a longitudinal incision made over the posterior edge of the deltoid, dividing the fibers of that muscle and exposing the head of the humerus, which was found to be dislocated on the back of the scapula; the capsule was denuded and the extremity of the bone turned out; a leaden spatula was pushed beneath the bone to protect the soft parts and excision with a saw, made of the upper extremity to the extent of three quarters of an inch. On examining the limb and moving it in different directions it was thought best to remove an additional portion of the bone, the second portion removed being nearly as long as the first; the hand was then brought forward across the anterior portion of the chest, where it lay in a very easy position without apparent difficulty; the edges of the wound were brought together by means of eight twisted sutures made with insect pins. In Phelps' case (No. 1), a curved incision was made along the lower edge of the deltoid in the scapula and the flap turned down; it would, he said, have been better to curve the incision downward and turn the flap upward, as it would give better drainage. The posterior edge of the glenoid cavity was gone, the cavity was about two-thirds the usual size; it was considered whether to enlarge the cavity or trim the head of the bone; it was decided to do the latter, because, had the cavity been enlarged it would have been necessary to shorten the humerus in order to replace it; the remote result might have been, in bringing the two raw surfaces together, ankylosis of the joint; a portion of the head of the humerus therefore was cut away in order to fit it into the socket; also a portion of the redundant capsule, posteriorly; the bone was replaced and a stitch put in behind to help retain the head in place. There was no complication following the operation, except in Phelps' second case, which suppurated. The immediate result is not mentioned in Post's case; in Phelps' No. 1 the drainage tube was removed at the end of a week; in case No. 2 a counter opening had to be made. The remote result not stated in Post's case; in Phelps' No. 1 it was very good, and in case No. 2 only fair. The operation is thoroughly indicated. Dr. Phelps says the method promised success during the first year, although one case has been operated in which it was successful in the fifth year; he gives no references.

22. *Irreducible dislocation in young subjects*, that is, in children and in subjects under 17 and 18 years of age, should be treated by reduction, if possible, or by resection of only the cartilaginous portion of the head. It is most important not to injure the epiphysal cartilage. The ossified portion of the head may be removed, but the epiphysal cartilage between the head and the shaft must be spared if possible. A horizontal section, with the saw starting at the internal insertion of the capsule around the head will surely carry away the totality of the conjugating cartilage.¹⁶ In young children, if the resection is made below the epiphysal cartilage the arm will cease to grow. The resected extremity should not be pushed into the glenoid cavity in children, lest the growth of bone cause ankylosis.¹⁷

23. *Irreducible dislocations, old, in old or debilitated subjects* should not be operated, except under very favorable local and general conditions, or under serious indications. Resection of one inch of the

shaft where it joins the head is best adapted to these cases.

24. *Irreducible dislocations, old and double, i.e., on both sides simultaneously, and operated,* have been reported three times: Lister (two cases), 1889-90; Reid, 1880. Lister's first case was operated by reduction on both sides, with an interval. His second case was operated by resection on the right side and reduction on the left. Reid's case was a double subclavicular, and the two sides were operated by resection at an interval of two and a half months. These cases have already been considered as regards operation, difficulties, etc. There are two or three more simultaneous double dislocations reported, but only one side was operated.

(To be continued.)

FIVE CASES OF SARCOMA OF THE HEAD AND NECK.

Presented to the Section on Stomatology, at the Forty-eighth Annual Meeting of the American Medical Association held at Philadelphia, June 1-4, 1897.

BY VIDA A. LATHAM, M.D., D.D.S., F.R.M.S.
CHICAGO, ILL.

Many times it falls to the lot of some practitioners to see in dental surgery cases of mistaken diagnosis which become interesting studies. The question may be asked, "is the mistake altogether the fault of the graduate in dentistry or due to insufficient opportunities?" In looking back we find the training of a dental student decidedly deficient in many branches, just as is true of the medical man. Take for example the subject of oral surgery. The general type of teacher is often the instructor or assistant to the professor of surgery in the medical department (if the institution belongs to a university), a man who has seldom done anything beyond the more common minor operations, who knows little or nothing of the needs of the dental surgeon, and who often regards the dentist as not needing to know much beyond a few minor surgical subjects, such as wounds, fractures and dislocations. Indeed, he often looks down upon the profession, regarding it as nothing more than a mechanical business. I have often heard the criticism made by the surgeons, "Of what use is an oral surgeon? No man who knows his profession would care to be so narrow. In fact it is useless to urge the need of such a specialty at the present time."

Plastic surgery of any kind requires considerable thought and skill to prevent serious deformities, and particularly is this so on the face, where diseased conditions usually demand severe operations, involving considerable areas and dangerous localities. An oral surgeon must be a broad-minded conscientious man, a profound and able diagnostician, and a graduate in medicine as well as in dentistry, for it is only by a combined knowledge that many of these cases can be treated successfully. It is men such as these who should be encouraged in their work, and asked to teach or operate in our dental colleges. Think for a moment how few are the colleges that possess such a chair or teacher! To Philadelphia belongs the honor of showing how much good work was done by our revered and kindly teacher, the late Professor James E. Garrettsen. Only a year or so before his death, when visiting the city, did the Doctor remark to me, "You little know the danger which arises from the indifferent training that is given in this line of work, and I do sincerely hope that before many years are gone

the dental profession will demand the increased teaching of the subject, together with pathology and histology." It is some pleasure to see that the work of his late assistant is bearing out some of the Doctor's ideas, and it is to be hoped that the profession will in every way encourage such scientific work. I have reference to Dr. M. H. Cryer, whose studies in dental anatomy and on the maxillary bones are certainly of great anatomic and surgical value.

Let us recall the number of times we have casually noticed growths in the mouth and its adjacent parts. They may have appeared small and perfectly harmless, and we perhaps have thought it unnecessary to caution the patient to avoid all dangers from uncleanness and irritation from rough stoppings or badly fitting plates, and in a short time have heard that the patient was suffering from a "tumor." I have seen and heard of the experiences often enough to have a vivid impression. There is a fault in our schools which is the cause of many such errors of judgment. The student is taught prophylaxis, in the abstract,

FIG. 1.—Epithelium, normal; early round-celled infiltration just showing in submucous tissue. (From myeloid of jaw.)

but no theoretical teaching can impress the learner so forcibly as even one practical illustration. The feeling of danger or seeming hopelessness with which an advanced sarcoma or carcinoma of the maxillæ or face is met in the clinic, will not require emphasis in the student's mind as to prevention or early recognition. Every practitioner or dentist at some time sees cases of just this nature, perhaps when the disease is in its earliest form. If he is able to recognize it and sound a note of warning, even though he may refer the case to a surgeon or specialist he has done a great favor to the patient.

Case 1.—Myeloid sarcoma of the jaw.—Not long ago I saw a case which had been sent to a dentist for advice regarding a right superior third molar that was troublesome. The patient was told to have the tooth removed, "as the wisdom teeth were of no value," and this was done. But there was no advice nor suggestion of anything suspicious about the thickening of the gum around the outer side of the tooth. After a few months the patient became a medical student, and as the "socket" showed some irritability, a junior teacher and dentist in the University Dental School was consulted. He pronounced the growth nothing but "thickened gum," and it was snipped off and thrown into the cuspidor, and the place touched with a styptic and counter irritant. In a little while it was thought

to be recurring, but the dentist said, "No, it is all right," and as he held a place in operative dentistry, and was quizmaster on the subject, the matter dropped. Only a few months later the patient transferred to a different school and heard a lecture on the subject, the importance of which created a feeling of uneasiness in her mind. At this time the student consulted me for examination and advice. The growth was small and seemingly fibroid in character, but the recurrence was suspicious and I asked permission to watch the case for a short time. Finding that it grew larger, I advised immediate and thorough removal, as I feared a sarcomatous epulis. After a little persuasion, the patient consented to the removal of a small piece of tissue for examination, and I herewith present two photographs chosen from a number of slides made from it. The first (Fig. 1) shows a rare section to all appearance, normal glandular structure and evidently the gland of Serres from the buccal cervical portion of the gum. Other slides from near this showed the ordinary histologic structure of the gum. The opposite end of the tissue from the neighborhood of the periosteal surface shows the early but rapidly growing and malignant nature of the tissue (Figs. 2 and 3) a typical myeloid or giant celled sarcoma. In consequence of this examination, the patient, who knew something of the danger of such a growth, was eager for a thorough, radical operation, which was done by a consulting oral surgeon. At the present time, after the lapse of eighteen months, there has been no recurrence.

FIG. 2.—Gland of Serres (a) in a case of myeloid sarcoma of the right superior mandible.

The great danger in this case lay in the fact that the growth first appeared behind and on the buccal surface of the gum near the third molar, and its easy course of progression would have been up the palatal process along the maxillary tuberosity and posterior palatine canal, so invading the antrum and palatoglossal folds.

It is generally believed that myeloid sarcomata are common in the maxillæ, though Bland Sutton says they are rare, and as a rule arise in connection with the nasal process. In the maxilla or mandible they arise from the body of the bone. Most text-books imply that these myeloid growths are fairly frequent in the alveolar borders of the jaws; but this idea is due to the fact that we know very little regarding their origin in connection with developing teeth.

In regard to the classification of myeloid sarcomata, or as Mr. Bland Sutton calls them "myelomata," there has been some recent discussion (*Edinburgh Medical Journal*, February, 1897, illustrated). Sutton thinks these growths have been too long confounded with the sarcomata, and agrees with Butlin and Colby in an article published in *St. Bartholomew's Hospital Reports* for 1895 on "Sarcoma of the Femur and Tibia." "If they are sarcomata, they differ from other forms in a manner which the modification of their structure does not suffice to explain." Sutton points out that they are only found growing from those parts of bones where red marrow exists, and that they grow from it, just as innocent cartilaginous tumors spring from the epiphysal plate. They grow, in fact, from one of the normal constituents of the bone. His important conclusion, that they differ histologically, pathologically and clinically from sarcomata, crystallizes the view which must have existed, though perhaps in a somewhat dormant condition, in the minds of many surgeons and pathologists.

There are two schools of practitioners, the conser-

FIG. 3.—Gland of Serres (b) from right superior maxilla.

vative and the radical, and I am well aware that both make mistakes. But knowing how patients are liable to postpone operative measures until too late, I take the position that it is best to follow the broad general rule, that "wherever an abnormal amount of tissue appears it should be thoroughly examined and if even suspicious, should be removed as soon as possible," whether it prove to be benign or malignant, for the following reasons:

1. The excessive growth injures the normal tissues by abstraction of nourishment, causing atrophy in some other part.
2. Atrophy produces interference with function of injured part.
3. The irritation caused by the foreign growth is apt to excite inflammation in adjacent structures, the process stimulating the cells to a hyperplasia, which

produces at least a deformity, or which may later become malignant.

4. There is danger that patients will avoid operation until it is impossible to give relief, as active growth in oral neoplasms is the rule. The location of these tumors is dangerous on account of the great blood supply; cavity formation occurring in the bones of the upper extremity, and because extension is easy to vital centers, as the brain and the eye.

5. There is considerable danger of sepsis from infection by micro-organisms of the mouth.

Case 2.—Small spindle celled sarcoma of the palate (Figs. 4 and 5).—According to William Anderson in Christopher Heath's "Dictionary of Surgery," sarcoma of the palate is rare, and when it does occur is usually of the round-celled variety, but one instance reported by him being found to consist of fusiform or myeloid cells. In looking over the literature of the subject I find few reports of primary tumors of the palate are recorded. I reported a few cases in the "World's Columbian Dental Congress Proceedings," and wish now to place on record a recent case of small spindle-celled sarcoma of the palate.

FIG. 4.—Small spindle-celled sarcoma. (Palate.)

The patient, a man aged 33 years, had been in perfect health up to six months previous to the time he came under my observation. What first attracted the patient's attention was a thickening on the left lingual surface of the palate. At first he was but little concerned, thinking it only a local irritation; but as it slowly increased in size he consulted a dentist, who told him it was a chronic inflammatory growth, and possibly due to his smoking a pipe. This habit was discontinued and the swelling treated by counter-irritation, which gave no relief. By this time the place was a source of annoyance, as the patient could not keep his tongue off it and he determined to have it removed by his family physician. The latter found that the growth extended from the first molar to the soft palate within half an inch of the uvula, and becoming suspicious of its nature he decided to be prepared for a radical operation and gained the patient's consent to do what he deemed best. The growth was periosteal in origin and was thoroughly extirpated, the teeth being extracted on that side and the alveolar border curetted, removing all tissue that looked even suspicious. So far there has been no recurrence.

The differential diagnosis between palatal abscess and sarcoma shows the following points:

Sarcoma springing from the periosteum of the hard palate appears as a soft, semi-elastic, more or less rapidly-growing tumor affecting the roof of the mouth. A palatal abscess originating from any of the upper teeth and burrowing backward beneath the bone and periosteum or in the soft tissues forming the roof of the mouth gives rise to pain, and inflammation attends its development: it extends more rapidly and gives an elastic feeling of fluctuation. There is the evidence of a carious tooth, and in chronic cases the diagnosis can be positively made by exploratory puncture.

Sarcoma of cheek (Figs. 6 and 7).—The patient, a healthy-looking woman aged 42, had detected, about three years before I saw her, a small, hard but freely movable lump behind her left ear, between the mastoid process and lobule. It increased slowly and painlessly until about six months before I saw her, when it began to grow rapidly and to cause considerable distress. The tumor was of a reddish-blue color, the size of a small tomato, which it resembled in gross appearance. The overlying skin was extremely thin, almost translucent, and apparently incorporated with the growth, which was only slightly movable on the subjacent periosteum. It threw the ear forward and from its lower border a hard ridge passed down behind the angle of the jaw and extended up in front of the ear nearly to the level of the second molar tooth. The operation consisted of a circular and a longitudinal incision, part of the ear lobe being carried away with the tumor, which was adherent to the periosteum and to the sterno-mastoid muscle, part of the latter being necessarily removed. The

FIG. 5.—Blood vessels with sarcoma cells in wall.

ridge-like process, a large portion of the adjacent parotid gland and some cervical lymphatic glands from the carotid sheath were also removed. The mastoid area from which the tumor was excised was treated with the thermo-cautery. Much misgiving was entertained as to the thoroughness of the removal, as when the periosteum is considerably affected, the bone is almost always involved, and it was impossible to remove any more of the mastoid process and squamous bone. After some months the disease recurred in some granulations which crept over the area of operation, and in spite of curetting, cautery, etc., the growth extended rapidly. The patient succumbed from pain and an exhausting discharge some nine months later, death occurring about four years from the beginning of the disease.

The origin of this tumor was doubtful, but I believe it to be in the lymphatic gland found on the mastoid process behind the ear. The patient had been subject to abscesses from badly decaying teeth, and had received treatment and extraction. She gave a history of repeated attacks of lymphangitis, in all probability septic and had complained to her dentist and physician regarding the stiffness of the jaw and neuralgic pain in the left ear. She was an intelligent woman and insisted that

"the doctors said the swelling (which was small when seen by them) was only from her bad teeth," and would get well when her mouth was better. Removal of the diseased roots had at first checked the sepsis from which she was suffering, but the pain about the swelling continued and her physician referred her to me, evidently thinking the neuralgia of dental origin.

FIG. 6.—Sarcoma of cheek.

FIG. 7.—Sarcoma of cheek.

It is quite possible that this case might have resulted more successfully had it received early diagnosis and prompt treatment by operation.

The photographs show the structure of a mixed sar-

coma, resembling alveolar, in parts showing masses of sebaceous epithelium and sweat glands and some hair follicles, with the large sarcoma cells grouped in masses. In parts a fibrous matrix runs among the cells, giving the appearance of alveoli.

Sarcoma of antrum (Fig. 8).—The patient, a well-built boy, 15 years of age, had complained of constant pain in the left upper first molar, which was treated. In about three weeks his cheek began to swell and on returning to the dentist the boy was told that the swelling was an abscess. Free incisions were made and no pus found. As he got no better and the pain continued the patient left his dentist, going to one of the well-known advertising houses, and there was told to have the

FIG. 8.—Sarcoma of antrum.

FIG. 9.—Melanotic sarcoma. (Neck.)

tooth extracted. This was done, and after the somewhat profuse hemorrhage which followed the pain was better. The swelling, however, did not disappear, and I saw the case upon recommendation of his family physician. The unilateral

bulging of the antrum and upward displacement of the eye—the slight amount of pain, together with the history and previous treatment led to a diagnosis of sarcoma of rapid growth. I gave the patient an unfavorable prognosis and urged a speedy removal of the upper jaw, which was done. When the soft parts were laid back the disease was found to be very extensive, requiring removal of the whole superior maxilla and malar bones, the zygoma and part of the temporal and masseter muscles. Hemorrhage was very severe, but was controlled by iodoform packing and tincture benzoin comp. In spite of this bold and severe operation the disease recurred and the patient died from exhaustion.

The microscope showed the tumor to be a small round-celled sarcoma.

Melanotic sarcoma of the neck (Fig. 9).—This specimen is from the neck of a woman 29 years old. It was situated at the angle of the jaw on the right side. The history is, briefly, that she had a dark brown pigmented mole in the above location, which annoyed her so much that she frequently "picked" it. About one year ago the mole seemed to be growing larger, but the patient was not alarmed until four months ago, when it commenced to increase in size very rapidly, to look inflamed, and to cause much shooting pain. Upon advice, the patient had the growth removed, which was done through an elliptic incision on each side at least one inch distant from the periphery of the growth.

As is well-known, pathologists are undecided as to whether this is a sarcoma or a carcinoma, though undoubtedly we possess both varieties. Sections were made in celloidin, paraffin and by freezing, the two last-named giving the best results. The majority of the sections show the tissue cellular in type, of mixed sizes and shapes, some with and some without pigment granules in the protoplasm, separated from each other by a variable amount of intercellular substance showing in some places a distinct fibrillation. In some places the pigment cells seem to invade the epidermis, as though the epithelium might be implicated in the growth, which layer is in connection with the cellular elements, and then further gives way for the usual normal subcutaneous connective tissue layer. The epithelium is not seen to be taking part in any of the growth, but here and there masses of sebaceous epithelium can be seen. The chief peculiarity of the growth is its superficial location and extent in a lateral direction.

The origin of the pigment is indefinite, the origin from blood being affirmed by Dressler, Kolaczek and Rindfleisch, and denied by others. Pigmented sarcoma cells do not fibrillate, which fact explains the great malignancy of melanotic sarcoma. The fibroplastic part of such growths is always made up of spindle cells which are not pigmented (Senn).

808 Morse Avenue.

SOME LITTLE POINTS IN SURGERY.

Read by request at the Twenty-sixth Annual meeting of the Southwestern Kentucky Medical Association, May 11 and 12, 1897, at Paducah, Ky.

BY E. B. SMITH, M.D.

DETROIT, MICH.

In preparing this paper I have endeavored to make use only of such points and suggestions as have come up before me in my every-day practice, and which I believe, are of daily thought and study to every surgeon who is actually engaged in relieving the suffering of humanity.

I am quite sure you will all agree with me that the little points in the practice of our profession are of pre-eminent importance. Of themselves, they are able to make or mar our success, according to our attention to or neglect of them.

In an injury to the head we must take into consideration every minute point, weigh each well and pro-

ceed as our best judgment dictates. If we suspect fracture of the skull we should examine the ears, and if a discharge is present, its nature should be noted, for on this—whether it be blood, the cerebro-spinal fluid or a mixture of them—will depend our diagnosis and prognosis to a large extent. The pharyngeal space and posterior nares should not be overlooked, and lastly, every surgeon should be conversant with the use of the ophthalmoscope and be able, roughly, to determine some of the more commonly occurring pathologic conditions of the fundus of the eye, such as choked disk, neuritis, hemorrhage, detachment of retina, and albuminuric retinitis, which conditions are liable to occur in cerebral apoplexy, meningitis, brain tumors, Bright's disease, and injuries to the head.

In all injuries about the body the positive, brilliant diagnosis is made by considering every little point; for example a man has been crushed between two heavy bodies and the head of the femur is thought to be involved. Everything that bears upon the question must be fully considered, and it will be found that the simple, plain little points will reveal the certain diagnosis. The position of the limb here, as in almost all fractures of the long bones, will indicate to the experienced surgeon, almost at a glance, just what the condition is. Yet it is well to fully corroborate the testimony of the eyesight with every means of evidence available. The result will then be safe.

In compound fractures a little point of importance is to make the right traction so as to fully reduce the fracture and yet produce as little secondary injury to the parts as possible, especially to the nerves and blood vessels. More than once I have hooked my little finger, rendered as thoroughly aseptic as possible, between the bones and soft tissues and used just enough traction to push the fractured end of the bone back into its original position. Again, it is a nice little point to know just how to cleanse and remove all débris from the wound. I always carry, both in my dressing and my surgical case proper, some fine rubber tubing. This can be made quite aseptic in a few minutes and an extemporaneous syphon made in as short a time. A sterile, neutral, alkaline or antiseptic solution can be prepared while the injured parts are being uncovered. I then apply to the wound my rubber tubing syphon, in one end of which a glass nozzle is fitted, in such a way that the inflow of water will drive out and not wash in the foreign material. In applying dressings it is a nice little point which comes only with practice to know just how snugly to draw them so as not only to hold the parts in position but give the patient perfect rest without pain. When the injury to the limb is below the middle third it is a good plan to pad the distal end well and begin the application of the bandage close to the extremity, bandaging somewhat firmly here, and as the bandage goes nearer and nearer to the wound making it slacker and slacker until the injured tissue is reached, when the bandage ought to be drawn only snug enough to simply hold the dressings firmly in place. I think the tendency is to apply too much dressing to stumps after amputations, and to extensive injury of soft tissues. I apply just as little as is consistent with the requirements of the case. When the patient is at home, with good atmosphere and sanitary surroundings, I am still more careful to apply as little dressing as possible.

In compound comminuted fractures the question is how many of the small fragments of bone to remove and how many or what to leave. It is good practice after having thoroughly cleansed the site of injury, to leave the cancellous pieces near uninjured cancellous bone, and to leave in place all peripheral portions which are attached to the periosteum, and thus if possible make the contour of the bone almost if not quite normal. One of the recognized procedures of modern surgery, when we have an extensive wound, be it operative or from accident, is to cleanse it with some substance that is as non-irritating as possible. The strong irritative solution of mercury bichlorid of the earlier practice in aseptic and antiseptic surgery is practically a thing of the past. For a thoroughly reliable antiseptic solution for irrigating wounds which are infected, I am in the habit of using 2 c.c. each of carbolic acid and tincture of iodine to a liter of sterilized water; I then rewash with sterilized water. Simple sterilized water, or sterilized normal saline solution makes an ideal cleansing fluid when we have no reason to suspect infection. For a dry dressing I use sodium chlorid and starch, in proportion of 1 to 4.

When called upon to go hastily to some remote house where an operation of some kind is found imperative, alone and partially unprepared, I usually proceed in the following manner: While my instruments are boiling in a soda solution on the kitchen stove, I prepare the patient. I then appoint three nurses if they can be obtained in the house or from the neighbors. One I assign to the anesthetic; the other two I make head-nurse and assistant, respectively. I then clean my hands, nails and arms, and instruct both nurses to do the same in every detail. I then say to them, "Do not touch anything with your hands or arms except as I direct." I then prepare my needles, dressings and instruments, placing all in a place convenient for picking up as needed; the assistant nurse handles the boxes, the jars and the pans only; the head-nurse may, if necessary, thread needles, cut gauze into convenient strips for sponges and assist me generally; I then put the patient under chloroform, give the inhaler to the nurse I have appointed for this duty, sterilize my hands again and then proceed with the operation.

In repairing the soft tissues, like structure should be brought into apposition with like, severed tendon to tendon, nerve end to nerve end, etc. To do this thoroughly, neatly and well, without too great tension, requires not only a delicate touch, but a firm, steady hand which experience alone will bring. To my young friends who are just entering the field of surgery I would say, "Perform operations on the cadaver, on the dog, the rabbit, anything you can get hold of. Do all kinds of work again and again until you feel that you are master of the situation, then when called upon to care for some unfortunate human being, you can enter the room of the injured or afflicted one with a confidence born of the certainty of success."

Do not use too heavy ligatures nor too large sutures. I wish to urge this very strongly. In my opinion the experienced surgeon can ligate vessels with a comparatively fine silk thread without running the slightest risk of cutting through the vessel; then with a well and neatly tied knot he can cut the ends quite close; and so too in tying off stumps. The point I wish to bring out is that the smaller the foreign substance which we leave in a wound or cavity the less liable

we are to have trouble and irritation. In suturing an external wound it is well to remember that all knots should be tied upon one side or other of the incision. If a knot happens to be tied directly over the incision it can as a rule be easily slipped over to one side. The reasons for this arrangement are two. If the knot is left immediately over the incision or cut surface, the ends may dip down between the edges and so prevent primary union. Again, when we come to remove the stitch we can catch the knot with a pair of fine toothed forceps and, with blunt pointed scissors, depress the integument at the stitch hole sufficiently to cut off the suture at some distance below the surface; then making traction on the knot in a direction away from the newly united edges the shortest possible amount of thread is drawn through, saving the patient pain and preventing infection by carrying some of the external part of the suture through the tissue. When placing stitches in a wound or incised surface, great care should be taken not to injure any deep lying nerves or vessels or any organ adjacent thereto by passing the needle too wide or too deep.

When proceeding with an operation, and this applies especially where the blood vessels are numerous and tortuous, for instance about the face, neck, chest and extremities, it is well to have a qualified assistant to compress the important vessels leading to the field of operation. This materially aids in shortening the operation and helps the operator do neater and better work. All vessels from which hemorrhage has occurred should be secured before entering any cavity beyond. I emphasize this point by stating a case of my own, that of a boy suffering from diphtheritic obstruction of the larynx. This case I ultimately lost with a septic pneumonia when a little more care in securing the vessels might possibly have saved his life. The abdominal surgeon realizes the importance of securing all vessels before he enters the peritoneal cavity. The genito-urinary surgeon is careful, when passing through the perineum, to check all bleeding points with ligature, or catch forceps, or to at least thoroughly pack the site of the wound so as to completely control all hemorrhage in this region before entering the bladder. In the operation of perineal lithotomy there is a little point that is well to bear in mind, viz., when the sound is in the bladder, and the incision into the bladder has been completed, it will be very embarrassing to the surgeon to accidentally or intentionally remove both sound and forceps before the calculus has been grasped. It is a very difficult thing to reintroduce them. I would advocate more general blood letting for cerebral apoplexy; for mastoiditis early incision and exploration if necessary; for cellulitis early and multiple incisions. After operations give as little anodyne as possible, none at all is better. Here codein is preferable to morphin, on account of its less depressing, less constipating after-effects. If morphin must be given it is preferable to use the hypodermic syringe. For the pain after an operation involving the brain, give bromids. For abdominal pain after laparotomy give teaspoonful doses of *hot* water and apply hot water to the abdomen, where it can be done without infecting or wetting the wound. Be careful to prevent vomiting after abdominal incision. This may be done by cocain spray to the nares, by laying a cloth wet with vinegar over the face, or by counter irritation over epigastric regions, etc. The pain, after bladder operations, may

be relieved by rectal injections of hot water, or when severe, by a suppository of opium: the same for pain following rectal operations, when not extensive. For preventing the extreme thirst following abdominal operations, it is a good plan three or four days before the operation to commence having the patient drink large quantities of water. In this way you will get rid of much of the thirst which is so intolerable after an extensive operation. There are points all along the road of surgery. Last, but not least, let me try to make a little point on thorough preparation, even in the smallest operations. When opening the smallest abscess, when removing a foreign body however minute, when introducing an instrument of any kind into a wound or into any of the natural cavities or orifices of the body, remember in all cases, to have your hands and instruments surgically clean; look well to the field of operation, see that it is as thoroughly prepared as though you were going to do a capital operation, for more than once you and I have seen disastrous results from not being careful enough.

A MODIFICATION OF THE MURPHY BUTTON.

BY ARTHUR E. HERTZLER, A.M., M.D.

HALSTEAD, KANSAS.

The time required to suture the ends of the intestines, and the necessity of pushing in the suture threads after tying the plates, and the uncertainty of an adequate opening, in the use of the decalcified bone plates of Professor Senn; the large size of the body to be extruded, the danger of lodgment and the occasional undue pressure of the spring, in the Murphy button; the time required to make a union by the Czerny-Lembert suture, seem a sufficient apology for continued investigation in the perfecting of a method for uniting the various parts of a digestive tract in case of disease or injury. That many advances along this line have been made is evident, and it is equally obvious that there is still room for improvement. It is with the hope of contributing to this advancement that this modification of existing methods is offered.

The present combination is the result of an attempt to unite the decalcified plates of Senn without the use of sutures. After using various devices, an exploded pistol shell was used. Little strips, two millimeters wide, were cut down the sides and bent outward to form hooks to catch in threads in the female part of the button, as in the Murphy button. The regular lock of the Murphy button was also used, but this locks only about every one-thirty-fifth of an inch, which was not sufficient. I used thirty-two caliber for cats, thirty-eight for small dogs and forty-five caliber for large dogs, in lateral anastomoses and colectomies. Four catches, instead of two, were used on the male portion of the lock, the two opposite acting together. This gives a firm lock and at the same time allows it to fasten every one-seventieth of an inch with a thread of one-thirty-fifth of an inch in the female portion of the lock. This allows accurate coaptation and does away with the necessity of a spring plate, as used in the Murphy button. At first a spring was used. A coil spring was placed between the head of the tube and a shoulder in the disc made to receive it. I found, however, that this is entirely unnecessary, as the slight elasticity of the disc is all that is needed.

Plates of fresh bone of from six to seven millimeters thick are cut into circles a little less in diameter than the gut it is intended to unite. Holes are now drilled just large enough to admit the central tubes. These are made larger and of lighter weight than the central tubes of the Murphy button of the same diameter. The inner side is now reamed out about the central opening for the puckered part of the gut to lie in after the draw suture has been tightened. All edges are now rounded, the discs decalcified and dried between filter paper, under pressure, then hardened in alcohol.

I have made more than a hundred experiments to determine the length of time necessary to decalcify, but the results are still not entirely constant. One difficulty that can never be entirely overcome is the fact that the various conditions of the digestive tract affects the rapidity with which the bone will be absorbed. Still, the results may be stated in a general way. For use in the intestines the discs should be decalcified for four days in a 10 per cent. solution of HCl of twenty-five times the volume of the discs, and changed but once at the end of forty-eight hours. After decalcification is complete the discs should be dried for twenty-four to forty-eight hours between several layers of filter paper, under pressure, and then hardened in alcohol of ascending strength, as in

1. Male portion, showing four catches which are adjusted to work in pairs. 2. Female portion, containing thirty-six threads to the inch on its inner surface. 3. The two decalcified plates separate from the metallic portion. 4. The button closed, showing how the central tubes slip into the plates and then shove together, like the Murphy button.

hardening tissue for the microtome. After hardening they may be kept in alcohol indefinitely. They have no tendency to warp, and are sufficiently firm for the purpose. A disc thus prepared will require about from 3 to 5 days time for absorption enough to take place to release the central tube. Discs intended for use in the stomach should be decalcified for twenty-four to thirty-six hours only, in fluid of the above strength, without change, and then dried and hardened as above described. Such a disc will absorb in from seventy-two to eighty hours. If the animal is given food absorption is hastened, while opium retards the process.

I have tried ivory and, while it is more easily worked, the time required for its absorption is not so constant, and is on the whole less desirable than bone.

Besides the usual rules observed in this class of operations the following points are suggested:

1. In end to end anastomosis the draw stitches should be regularly placed and should not include too much tissue, two millimeters is enough.
2. In gastro-enterostomy a circular patch of tissue,

the size of the central tube, should be cut out of the stomach and intestinal walls. An opening of this size will stretch over the disc and give a snug fit without wrinkles, making a most perfect coaptation.

3. In uniting the two parts of the button, they must be firmly pressed together, tighter than a Lembert suture would be drawn. At the same time the tissue must not be unduly crushed. This is the most particular part of the operation, and if rightly done removes the necessity of a spring, the slight elasticity of the discs, as before stated, being all that is required.

By this method the following points of merit are believed to be obtained in the highest degree:

1. The junction is strong and food may be given at once if this seems necessary.

2. No foreign body remains after union is complete.

3. The small size of the body to be extruded. This is an important point should there be a constriction below.

4. In gastro-enterostomy the button can not become lodged in the stomach and cause trouble. In the stomach the disc becomes digested off first, forcing the remainder into the intestine. Even should the disc, in the intestine, be the first to become absorbed, after the remaining disc is digested, the central tube will pass out readily.

5. It can be as quickly applied as any method known.

6. There are no sharp points in contact with the intestinal wall.

7. The opening is as large, and has as little tendency to contract, as that obtained by any method heretofore employed.

This method has never been used on the human subject, but judging from results obtained upon animals, it seems to leave but little to be desired.

SOCIETY PROCEEDINGS.

American Surgical Association.

Thirty-ninth Annual Meeting, held at New Orleans, April 19, 20 and 21, 1898.

FIRST DAY—MORNING SESSION.

This session was devoted to an address of welcome by Dr. J. HOLT of New Orleans, announcements of various committees and the reading of the President's Address on

THE FUTURE OF THE ASSOCIATION,

by Dr. T. F. PREWITT of St. Louis.

After referring at some length to the formation and organization of the society, he referred briefly to some of the men who had preceded him in the office of president and particularly to the founders of the Association. He then dwelt upon the character and standing of the present and future members and particularly in reference to their standing and advances in surgery. In commenting upon the achievements of the nineteenth century he referred to the progress of railroads, steamboats, telegraph, telephone, electric light, photography, to say nothing of the rapid strides in surgery, and urged the earnest and cordial co-operation of all distinguished surgical practitioners, writers and teachers in enabling the Association to occupy the proud position its founders destined for it.

FIRST DAY—AFTERNOON SESSION.

Dr. CHARLES A. POWERS of Denver read a paper entitled
THE QUESTION OF OPERATIVE INTERFERENCE IN RECENT SIMPLE FRACTURES OF THE PATELLA.

The author opened his paper by quoting extracts on the subject of writing by Dennis, Bull, Czerny and Myles and then took up the tests, first structural and second functional, for fracture of the patella. In referring to the mechanism he stated that the majority of his accidents were due to muscular action, the patient endeavoring to save himself from falling, the quadriceps femoris being strongly contracted at the time.

In taking up the question of the pathology it was shown that in the fracture due to muscular action there are but two fragments, of which the upper is generally the larger, while the fractured surfaces are as a rule irregular and the line of fractures may be transverse or oblique. In commenting upon the conditions tending to cause imperfect union and the obstacles to union, the author enumerates them as follows: 1. Separation of fragments, due to: *a.* Retraction of the upper fragment from contraction of the quadriceps femoris and a slight drawing down of the lower fragment through a shortening of the ligamentum patellae. *b.* Effused blood. 2. Tilting of the fragments (this may be present to a marked degree and unrecognizable without operation). 3. Rupture of the tendinous expansion of the vasti and of the lateral portions of the capsule of the joint. 4. Prolapse of the pre-patellar tissues into the breach. 5. Atrophy of the quadriceps femoris due to: *a.* Disuse. *b.* Arthritis. *c.* Marked contusion of the muscles. *d.* Blood extravasated from the joint through the rent in the upper part of the capsule. 6. Arthritis of the knee-joint, this possibly resulting in, 7, adhesion of the patella. Further, though of but little value, may be added, 8, natural poverty of the blood supplied to the bone (rendered negative by the fact that vertical fractures healed satisfactorily), and 9, exceptional tendency to osteitis, seen in fat people, in the aged and in certain conditions of the blood. As to the non-operative management of these cases the speaker considered that no better evidence of the unsatisfactory results attending treatment of fractured patella by mechanical means need be adduced than the great variety of plans and devices which have been set forth from time to time. A few of these devices were referred to, among others the use of properly applied bandages or strips of plaster followed by a splint or plaster-of-Paris dressing, Malgaigne's hooks and the so-called "Dutch" method or massage.

Dr. Powers then quoted at great length from a very large number of personal letters from prominent surgeons all over the United States, each setting forth his opinion and preference as to the treatment of these cases. Elaborate statistics follow giving the results of various kinds of treatment by many different surgeons and showing comparative mortalities from the different methods. The subject was then taken up very fully under the headings of: "dangerous," "limitations attending the operation; selection of cases," "time of operation," "operative procedures" and "immediate and remote results of operative management and comparison of these results with those attained without operation."

Dr. J. D. BRYANT of New York, in discussing this paper, referred to the work of the late Prof. Frank H. Hamilton on this subject and, in computing the comparative worth of the different methods, called attention to the importance of the following determining factors: 1, the degree of physical infliction; 2, the duration of confinement in bed as bearing respectively on the comfort, health and business demands of the patient; 3, the character and importance of inherent and acquired complications of respective methods of operation; and 4, the final burdens imposed by the sequels of different plans of cures. The Doctor then discussed these four points at considerable length and again quoted to some extent from the writings of Hamilton. He stated that he was not inclined to the practice of suture in the patella except in instances emphasized by a special indication for that step, but he considered it a justifiable measure in selected cases.

The technic of operations which he at present employs consists: 1, in making a short vertical incision; 2, removing the blood clots from the fractured borders of the bone along with the interposed fibrous tissue that is sometimes present, and cleansing the joint cavity; 3, draining the joint with a few strands of silkworm gut at the outer side; 4, uniting the fracture with a small wire so placed as to cause retention, and proper apposition of the fragments; and 5, closure of the wound, antiseptic dressing and fixation in bed for two weeks, followed by plaster-of-Paris spica and out of bed on crutches.

In conclusion, he called attention to a mechanical method of treatment wholly or in part employed by himself in the treatment of fifteen cases of simple fracture during the last twenty years, for which he claimed: 1, greater comfort and efficiency; 2, less danger and only a week's confinement to bed; and 3, results equal to the best of other mechanical methods. Drawings illustrating this method were shown.

Dr. M. H. RICHARDSON of Boston referred to the importance of good surroundings, good health of the patient, surgical experience and experience in aseptic technic in the treatment of these cases. In his opinion there was no need to open a joint if one could get complete control of extension, and where this is lost owing to extensive laceration, he thought wiring should be seriously considered. He was also of the opinion that the time of confinement in ordinary cases should be six

months. He defined aseptic healing as being an unsuccessful infection and believed that a wound of the knee-joint was especially liable to infection. The wiring of the patella he thought should be considered when the failure of conservative methods had been demonstrated.

Dr. JAMES E. MOORE of Minneapolis, felt that Dr. Powers' paper represented the opinion of American surgeons of the present day and commented on such a low mortality as less than 1 per cent., believing it to be better than the best results reported by using non-operative means. He laid great stress upon the importance of asepsis, proper environment and surgical experience in performing operations about the knee joint and believed that the passage of ligaments around the patella would be more fatal than an open arthrotomy. He was in favor of immediate operation and considered that approximation of the fragments would thus be rendered easier. Referring to the matter of technic, he believes the best results will be gotten by temporary drainage so as to avoid over-distension and interference with circulation. He does not feel, however, as mentioned by Dr. Richardson, that the amount or separation is any index as to the future usefulness of the limb.

Dr. W. S. HALSTED of Baltimore was not in favor of draining in every case, but thought it well to do so when the tissues about the wound were not themselves in shape to take care of the micro-organismal infection. He was in favor of immediately opening the joints and thoroughly washing out, and preferred to at all times wear rubber gloves during these operations.

Dr. POWERS, in closing the discussion, stated that in the body of his paper he had expressed the opinion that if a surgeon felt competent to undertake one of these operations he should feel equally safe in dispensing with drainage.

Dr. NICHOLAS SENN of Chicago, read a paper entitled

THE ETIOLOGY AND CLASSIFICATION OF CYSTITIS.

After dwelling at great length on the anatomico-physiologic construction of the bladder, and referring to its lack of absorptive power, the author took up the question of the etiology, which he divided into, under the head of predisposing causes, retention of urine, unrest of the bladder, abnormal urine, tumors, calculus and foreign bodies, pressure, exposure to cold, venous stasis and trauma. Under the heading of exciting causes, he mentioned first infection to the urethra, infection by the urine, infection from adjacent organs, infection from the blood, etc. He then took up the subject of classification, and after mentioning Guyon's classification, divided the subject into: 1, the anatomic; 2, the pathologic; 3, the clinical; and 4, the bacteriologic. He then subdivided the anatomic into pericystitis, paracystitis, interstitial cystitis and cystitis; the pathologic into catarrhal cystitis, suppurative cystitis, ulcerative cystitis, exudative cystitis and exfoliative cystitis; the clinical into acute cystitis, chronic cystitis, and the bacteriologic into staphylococcus infection, streptococcus infection, bacillus coli communis infection, saprophytic infection, diplobacillus infection, streptococcus erysipelatosus infection, gonococcus infection and tubercular infection. Each division and subdivision was discussed at great length and the details of many series of experiments were outlined in full.

Dr. JOHN PARMENTER of Buffalo, N. Y., in discussing this paper referred to the remark that the bladder did not possess any absorptive power and mentioned his experiment of injecting into the bladders of twelve healthy, eight drops of sulphuric ether in a drachm of water and detecting the odor of ether on the breath within a minute. He also pleaded for greater care in the disinfection of the urethra before sounding and considered that the infection was usually due to a combination of traumatism and micro-organism.

Dr. W. S. HALSTED of Baltimore, referred to the work of Dr. Young, one of his assistants, in this connection, and stated that Dr. Young had found the gonococcus was sometimes present in acid urine, sometimes in neutral and once in alkaline.

Dr. ALEXANDER of New York, took exception to Dr. Senn's statement that the mucous membrane of the bladder was devoid of glands, and mentioned that lymph nodules were almost always present in the bladder and the ureters, giving rise at times to a peculiar inflammation which he had termed nodular cystitis. He also referred to some recent investigations tending to prove that in a proportion of normal bladders in which the middle portion of the prostate was enlarged, accessory prostatic glands were found around the trigone of the bladder. He believed that retention was responsible for most cases of inflammation of the bladder and stated that an appreciable amount of residual urine is found in cases of moderate degree of stricture or a moderate prostatic congestion as a result of sexual hyperemia. Referring to the question of traumatism, he thought this was often due to destructive diseases brought

about by the irregular catheterization of the patient, and mentioned that where a patient suffering with prostatic enlargement is catheterized with an absolutely and perfectly clean catheter, still infection will at times take place. He also explained that if a man is catheterized at nine o'clock in the morning, again at five or six in the afternoon and not again until noon the next day, trauma will be produced by over-extension permitting the more rapid occurrence of infection.

Dr. SENN closed the discussion by stating that he thought the appearance on the breath of the smell of ether so quickly in Dr. Parmenter's cases, was due rather to a process of diffusion than of absorption, as he believes the urethra and neck of the bladder possess absorptive power, but that the vesical mucous membrane proper did not.

SECOND DAY—MORNING SESSION.

Dr. W. S. HALSTED of Baltimore, read a paper entitled

OPERATIVE TREATMENT OF CARCINOMA OF THE BREAST.

After referring at great length to a large number of cases seen and operated upon, and giving the statistics of the results for the past nine years at the Johns Hopkins Hospital, he referred in detail to the undescribed, not infrequent, cancerous tumors of the breast, to the relative malignancy of the various breast cancers, to the frequency, significance and treatment of cancerous supra-clavicular glands, and then referred in some detail to the operations themselves as performed by himself and his assistant.

Dr. CHARLES B. NANCREDE of Ann Arbor, in discussing this paper said that he was struck by the large number of cases of cancer of the breast occurring under thirty years of age, and that he had a limited experience of between 200 and 300 cases. A girl in the early part of her 25th year, who unquestionably had the same tumor in her 19th year, was operated on this winter by him. He asked if any one's experience coincided with his as to the large number of cases that occurred before the age of 30 years.

Dr. ROSWELL PARK of Buffalo, inquired what Dr. Halsted's teaching was with regard to endothelioma.

Dr. M. H. RICHARDSON of Boston, referred to the work done by Dr. Halsted, and stated that he had observed many cases where there had been no infection of the axillary glands. In two cases he had made the diagnosis of a tumor merely upon the symptom of pain. He believed that there was usually early recurrence of cases in which the axillary glands were infected. In commenting on the value of gross appearances he referred to a case where the microscopic appearance did not at all agree with the diagnosis, although the clinical appearance proved its correctness. In his opinion three years was not enough to consider a case cured, as he had seen recurrences in from seven to ten years.

Dr. J. D. BRYANT of New York, stated that he had found enlarged glands in the axilla in some cases where the increase in size was not sufficient to warrant the belief that the glands were infected, until a microscopic examination had been made. He commented on the fact that patients possessing a morbid growth not only very often kept this fact to themselves, but their physicians encourage them in so doing.

Dr. J. MCFADDEN GASTON of Atlanta, commented on the occasional disappearance spontaneously of carcinomatous formation and inquired if constitutional measures employed synchronously had been observed to have any effect.

Dr. ROSWELL PARK continued his discussion by stating that he had for several years been collecting data on the subject of the spontaneous disappearance of tumors and was anxious to get as much information on the matter as possible.

Dr. RUDOLPH MATAS of New Orleans, in discussing this paper, gave a lengthy synopsis of twenty-seven operative cases of malignant disease of the breast or its immediate vicinity, which had come to his notice between the years 1887 and 1898. There were no fatal cases from operative causes. Eleven of the cases are living and well and one has had three recurrences in three years and ten months. In two cases death resulted from accidental causes not connected with the operation. In performing the operations two excisions were done, eight Gross operations and seventeen complete (Halsted and Meyer) operations. One case which survived two years died finally from metastatic cancer of the uterus. The male operated upon is still living, eight years later, and is free from local recurrence. The author then referred at length to fifteen complete operations performed since November, 1894, and gave the results in detail. In conclusion he gave a synopsis of five cases that are living without recurrence, after complete operation.

Dr. F. H. GERRISH of Portland, Me., referred to the work done by Dr. Halsted and to the fact that a recent text book contains scarcely anything on the subject. He then referred

to the various operations which have been performed and showed how, step by step, the present method was arrived at. He considered that one of the most important points was the necessity for the removal of all mammary tumors whether benign or malignant. He also laid great stress upon the thoroughness with which the operations should be performed and the length of time required to do it. After commenting on the hopefulness of the prognosis in these cases at the present time, he referred to the fact that many cases referred to in the author's paper would until recent years have been regarded as absolutely unfit for operation.

Dr. HALSTED, in closing the discussion on his paper, said he was surprised to learn that Dr. Matas had had such marvelous results in operating by the old methods. As to age, he had seen one case at about 28 or 30 years of age and had also had one of cancer of the liver at the age of 21 years. Referring to Dr. Park's inquiry as to the teaching regarding endotheliomata, he said this was a difficult question to answer. These tumors, as far as they go, are believed by some to be alveolar sarcomata, and there are no doubt some examples of sarcomata where evidence is found of endotheliomata, as for example in the parotid and the testicle. With regard to the spontaneous disappearance of tumors, the author remembered one typical case of cancer of the breast in which this occurred, and also a case of epithelioma of the face. With regard to the non-involvement of the glands of the axilla, different surgeons had different experiences and no rule could be laid down on the matter.

AN INQUIRY INTO THE ETIOLOGY OF CANCER WITH SOME
REFERENCE TO THE LATEST INVESTIGATIONS OF
THE ITALIAN PATHOLOGISTS.

was presented by Dr. ROSWELL PARK of Buffalo, who stated that to attack this problem successfully pathologists of the future must begin by studying tumor formation in the vegetable world before studying it in animals, *i. e.*, the comparative method of investigation must be adopted, as the xylomata or woody tumors are so exceedingly common that they have failed to attract the attention which they deserve. The lipomata are the most frequent, frequently multiple, usually symmetric and of traumatic origin. The fibromata are usually of traumatic origin and the majority contain foreign bodies which have acted as the exciting cause. The myofibroma of the uterus is, strictly speaking, a leiomyoma and, according to Billroth, always commence by formation around a small blood vessel. Chondroma is most common in infancy and childhood and practically inseparable from rickets. Osteoma is often seen as an exostosis or as an ossification. Adenoma frequently becomes converted into carcinoma. The only two theories worthy of consideration in reference to malignant tumors is the embryonal and parasitic. In the vegetable kingdom it is hard to distinguish between various grades of malignancy, but nevertheless that tumors kill a large proportion of trees and shrubs will not be disputed by those who have studied the subject. Cancer has been happily defined as an abortive attempt of gland epithelium to reproduce itself, and sarcoma is a similar process pertaining to mesoblastic cells. It used to be taught that cancer was exceedingly prevalent at certain ages, but the author stated that, living in a region where cancer is exceedingly prevalent, he had witnessed the ravages of the disease in many relatively young people.

Among the many clinical considerations pointing to the study of cancer the writer mentioned influence of sex, age, brunette or blonde, heredity, size of heart, arteries and lungs, and geographic locality. As to the influence of sex, Dr. Williams has found that for every 100 males dying of cancer, 225 females perished from the same disease. With regard to age, the most prolific cancer-producing age is between 55 and 65 years. Williams has also found that, at least among females, the disease is twice as frequent in brunettes as in blondes, while Beddoe states that red haired individuals are the most exempt of all. As to heredity this is one of the most vexed questions, and opinions differ very much. Patients with large hearts, arteries and small lungs are often the subject of cancer, whereas in tubercular patients the opposite is true. Speaking geographically, cancer is certainly on the increase in certain parts of the world, and so true is this that the neighborhood of Buffalo, N. Y., has been termed "tropic of cancer."

The question has often risen as to whether cancer can be disseminated through the agency of insects and whether water, especially in the neighborhood of woods, could act as a medium of transport, which it is believed is at present conceded. Up to the present time experimental auto-inoculations have practically failed.

Taking up the subject from a historic standpoint, the writer, with Roncali, divided the past few years into four periods, *i. e.*,

The period of inaccurate observation and erroneous conclusion which began with Nepveau in 1872; the period of accurate observations and inaccurate conclusions, which is essentially the coccidial period and began with the discovery by Halle, Virchow and Gubler of protozoa in human tumors; third, the iconoclastic period of doubt as to the accuracy of all past researches, beginning with Russell's work in 1890 and ending with the research of Banti and Nisser in 1894; and the period of successful inoculation, practiced for the most part by Italian pathologists. As an illustration of Roncali's method of securing cultures, he prepared in one case sixty tubes of distilled water containing a little sugar and acid, and in each of them he placed small bits of tumor cut with a sterilized knife. These were kept at 37 degrees C. for ten days, when surface growths were found upon thirty-seven of them, which when examined in the hanging-drop were easily recognized as blastomycetæ. In conclusion the author stated that when it comes to the detection of fungi in microscopic sections the methods are more or less complicated and require considerable training in special manipulation and observation and gave in detail two methods for this work.

Dr. J. McFADDEN GASTON of Atlanta read a paper entitled

REMEDIAL MEASURES IN OBSTRUCTION OF THE COMMON
BILE DUCT.

He said that cases of jaundice which result from the temporary closure of the common bile-duct are usually left to the treatment of the physician and yet are the precursors of derangements which require surgical interference. They commence with functional disturbance, but terminate in organic derangements. Murphy lays great stress upon the relief of jaundice by pilocarpin. The reliance of the greater number of practitioners for relief in this class of cases has been, and continues to be, upon the phosphate of soda. But there have been more good results claimed from the employment of olive oil internally than from any other remedy of this class. After exhausting medicochirurgical means of treatment for biliary complications, without arresting obstruction of the common bile duct, the surgeon is confronted with conditions calling for operative interference. There may exist a stenosis or stricture of the walls of the duct, without occlusion of the canal, dependent upon inflammation, or there may be a partial obstruction of the lumen of the duct from the presence of a gall-stone which permits the bile to pass around it to a limited extent. In some cases Fenger has demonstrated that a gall stone may be so located as to form a valvular closure. Though an outlet may be artificially provided for the bile by connecting an opening in the gall bladder with one in the abdominal wall, there is not always relief to the cholemia, and its effects upon the general health of the patient continue even to a fatal termination. In a case presenting no enlargement of the liver, the incision should be made on a line an inch and a half below the border of the costal cartilages, and should be about three inches in length. He said that he had elsewhere given an unfavorable opinion in regard to exploratory puncture, and does not consider it entitled to recognition as a means of diagnosis or measure of treatment. The various measures recognized for the relief of obstruction of the common duct by gall-stones are, breaking up of the calculi by the needle, crushing by padded forceps, forcing them into the gall bladder or duodenum, catheterization and excision through the walls of the duct. In some cases it is impracticable to attach the gall bladder to the parietal opening or to suture the incision in the wall of the duct when a stone is extracted, and thus it becomes necessary to provide for drainage by packing with gauze around the field of operation, leaving the ends of the strips extending out of the wound.

In doing operation upon three white women for obstruction of the common bile duct, by forming a fistulous opening for the bile externally, the cholemia persisted in an aggravated form until death supervened in each case. In some conditions of temporary impediment to the flow of bile through the duct into the duodenum, the attachment of the incised gall bladder to the parietal opening has relieved the obstruction and been followed by the restoration of the bile. It is in order to state that only in complete occlusion of the duct, which has proved intractable to other procedures, has an artificial opening from the gall bladder or common bile duct into the alimentary canal been thought proper. This anastomosis is effected in various ways, either with the duodenum, the small intestine or the colon, the last named being least desirable, as it fails to secure the advantages of the bile in the process of intestinal digestion. My experiments upon dogs demonstrated the feasibility of this fistulous communication of the gall bladder with the bowels, and it is a matter of minor importance by what process it is accomplished.

The statistics in the past show that the various modes of procedure are comparatively free from danger and are attended with a marked degree of success, so that we may reasonably expect cholecystenterostomy to be recognized as a safe and efficacious recourse in the future annals of surgery.

Dr. H. W. CUSHING of Boston, read a paper entitled

TRAUMATIC RUPTURE OF PANCREAS; FORMATION OF HEMORRHAGIC CYST; OPERATION FOLLOWED BY A PANCREATIC FISTULA AND RECOVERY.

He reported a case in which a blow on the abdomen had caused a rupture of the pancreas followed by the rapid formation of a larger pancreatic cyst simulating closely an abdominal aneurysm. Four weeks after the injury he evacuated the cyst through an abdominal incision and drained it. The wound in the pancreas was found near the mental tubercle, but the critical condition of the patient contraindicated any attempt to suture it. For two days the patient was quite dangerously ill. On the third day following the operation a subphrenic abscess was evacuated through a bronchus and the patient rapidly recovered. There was a profuse discharge of pancreatic fluid from the abdominal wound. The cyst contracted rapidly to a small sinus, which healed on the seventy-seventh day after the operation. The case during its convalescence furnished the rare opportunity for an investigation of pancreatic fluid in a human subject. This showed a fluid strongly alkaline; specific gravity 1011 instead of 1030 as is usually stated. It removed the epidermis of the patient whenever it came in contact with it, causing great discomfort. It did not effect the peritoneum. The rate of secretion was measured and varied from 5 to 60 c.c. for an hour. The maximum was during digestion. The total daily amount was 500 to 660 c.c., or double the amount generally stated by physiologists. The complete analysis and the physiologic reactions were reported in full. The patient when last seen, fifteen months after the injury, was well and showed no functional disturbance of any alimentary process.

Dr. W. W. KEEN of Philadelphia, spoke of the rarity of these cases, and mentioned one occurring in his own experience. In this case there was no wasting of the patient, no sugar in the urine nor any fatty stools. He believed that ordinarily one should be content to simply open and drain.

Dr. W. S. HALSTED of Baltimore, referred to four or five cases of pancreatic cysts occurring in his practice.

Dr. T. F. PREWITT of St. Louis, commented upon a case of enlarged spleen which came under his observation fifteen years ago. Upon operation it was found that a cyst of the pancreas was connected with it. The cyst was tied off and the woman made a perfect recovery. A second case was that of a patient who had been in bed for four months and had lost much flesh. Upon cutting down in the median line over a swelling, much pus and fluid was found, and it was observed that the tumor extended to the backbone, necessitating a counteropening. A large calculus was found and removed, and was believed to have been the cause of the trouble. This calculus was supposed to be pancreatic in origin.

Dr. N. B. CARSON of St. Louis, read a paper entitled

CEREBELLAR TUMORS.

He stated that his object in reading the paper was to add somewhat to the literature on the subject, and to call attention to a symptom which has been much overlooked or neglected, namely, the so-called "Cranial Cracked-pot Sound" due to separation of the sutures from internal pressure, caused by the accumulation of fluid in the brain cavities produced by the closing of the latter or pressure upon the veins of Galen or both. After referring at some length to the history and treatment of four cases in which this sound was present, he stated that this sound must not be mistaken for the high pitched sounds present in some cases of brain tumor. It is not necessarily a sound of childhood either, but may be present at any period before the sutures have become permanently united. In an analysis of forty-nine cases of cerebellar tumors the author had found mention made of the presence of hydrocephalus in twenty-two of them, which makes this sound an even more important symptom. In an examination of the literature Dr. Carson could only find reference made to this "Cranial Cracked-pot Sound" twice, which led him to conclude that the symptom had been overlooked.

Dr. W. W. KEEN of Philadelphia, in discussing this paper stated that the first time his attention was called to the sound was by a patient who had noticed it when feeling his head soon after fracturing his skull by falling through the roof of a veranda. He believed it would be found to be a symptom of value, especially where there was doubt as to the existence of the fracture and the necessity for operation. As to hydrocephalus, he had observed this in many cases in the acquired form and moderately early for some years past. Where the edges

of the bone have separated it is impossible to get this sound, but early in the case it may be gotten and heard as much as ten feet from the patient. In his opinion it should receive more attention in the future.

Dr. DEFOREST WILLARD of Philadelphia, referred to a case of hydrocephalus recently brought to his office, in which the existence of a cerebellar tumor was suspected. And in this case the sound was absent, although it could hardly have been expected, as the child was less than a year old. There was total lack of cerebral development and extreme rigidity of all the muscles of the body.

Dr. CARSON stated that it was true that this sound was only present in cases of acquired hydrocephalus and extensive fracture of the skull. He agreed with Dr. Keen that where the sutures are widely separated the sound is not likely to be elicited.

Dr. W. W. KEEN of Philadelphia, read a paper entitled

CASE OF APPENDICITIS IN WHICH THE APPENDIX BECAME PERMANENTLY SOLDERED TO THE BLADDER, PRODUCING A URINARY FECAL FISTULA.

The case occurred in a man of 24 years of age, from whose urethra, at the age of 7, a pin was removed, no history of the insertion of which was obtainable. Some years subsequently the patient suffered from a supposed abscess of the prostate, from the spontaneous bursting of which a fecal fistula was established between the bladder and the rectum, and several attacks of cystitis followed. Numerous efforts were made to locate the two ends of the fistula, and the conclusion was reached that the rectal end was very near the surface. At the age of 25 years he was first operated on and a perineal section done, but the fecal fistula still continued. The formation of an artificial anus was then decided upon, the result of which was not altogether satisfactory, fecal matter frequently passing into the bladder before any was passed out of the artificial anus, and after eating strawberries the seeds were found in the urine before any escaped from the anus. These facts seemed to indicate that the fistula was between the bladder and some point in the intestinal tract considerably above the site of the artificial anus. The third operation was consequently performed and a very long appendix found dipping into the pelvis, the tip lying just behind the prostate and solidly incorporated into the wall of the bladder. A cuff of peritoneum was dissected from the appendix and used to cover the stump and the meso-appendix was then divided. The cecal end of the appendix was treated in the same way and the abdominal wall closed without anything being discovered in the way of a point of connection between the bladder and the bowel. Subsequently a fourth operation was performed to close the artificial anus and to destroy a spur which existed at the site of the anus, so as to destroy the entire caliber of the bowel. Shortly after leaving the hospital attacks of vomiting and constipation occurred and twenty-four days after the last operation the patient died. At the necropsy, twenty-seven hours later, the one striking fact observable was the absolutely black color of the small intestines in the lower part of the abdomen, and examination showed that seven or eight feet of the ileum had been rotated to the right in one vast volvulus. Its mesentery formed a band which stretched across the ileum just before it joined the cecum, and this had evidently obstructed the ileum sufficiently to cause gangrene.

The diagnosis of a prostatic abscess was a very reasonable one as so long an appendix dipping into the pelvis and anchored by its meso-appendix immediately behind the bladder and a terminal appendiceal abscess so close to the prostate might well be mistaken for this condition. The possibility of the involvement of the appendix never occurred to those in attendance. Although appendicular abscesses bursting into the bladder are not at all uncommon, I know of no case in which the appendix has been so thoroughly united to the wall of the bladder as to form, as it were, a third ureter. While it may be said that a fifth operation in the form of an exploratory abdominal section should have been done, the uncertainty of the diagnosis, together with the fact that the patient had been operated on so much, caused me to refrain.

Dr. ROSWELL PARK of Buffalo, referred to two cases in which pins had been found in the urethra, and in neither case could the patient explain how the pins got there, but he believed they had probably been swallowed. He stated that he had oftener found pins in the appendix than grape seeds.

Dr. N. B. CARSON of St. Louis, mentioned one case in which a pin had been found in the urethra. He also referred to a case of remarkably long appendix. It was a horse-shoe shape and he thought it was the longest on record, being about thirteen inches.

Dr. KEEN, in closing, said it was quite possible that the pins had been swallowed.

Dr. GEO. R. FOWLER of New York, read a paper entitled
THE USE OF ANIMAL TOXINS IN THE TREATMENT OF INOPERABLE
MALIGNANT TUMORS.

He discussed the subject under various heads, among others, "The Cure of Malignant Disease by Accidental Erysipelas," "The use of Septic Products of the Streptococcus Erysipelatis," "The Use of the Mixed Toxins of the Streptococcus Erysipelatis" and the "Bacillus Prodigiosus," "The Dangers of the Treatment," "The Condition of the Tumors under the Influence of the Erysipelas," "Treatment with the Toxic Blood Serum of Animals Infected with Streptococcus Erysipelatis," "The use of the Venom of the Cobra Capella" and "The Influence of Artificially Produced Suppuration upon Malignant Growths." This paper being read by title was not discussed.

A paper by Dr. L. C. LANE of San Francisco, on the "Hypertrophy of the Prostate Gland and Suggestions in Regard to its Treatment," was read by title.

After giving the location and average size of the normal gland together with its principal constituents, the author referred briefly to various palliative methods of treatment as well as operative. He believed that castration would have a permanent place in the treatment of prostatic enlargement in the future. He then quoted briefly from two cases upon which he had operated, one of whom died and one recovered.

Dr. MORRIS H. RICHARDSON of Boston, read by title a paper entitled "Rapid Disappearance of an Apparently Hopeless Sarcoma of the Scapula with an extensive Streptococcus wound Infection;" also a paper entitled "A Case of Violent Streptococcus Infection of an Amputation Wound, with Three Months' Treatment by Antitoxin Injections of a Round Celled Sarcoma of the Ankle."

Dr. DAVID W. CHEEVER of Boston, read by title a paper on "Some Cases not Operable."

THIRD DAY—MORNING SESSION.

This was devoted to Council and Executive Meetings.

AFTERNOON SESSION.

Dr. T. F. PREWITT of St. Louis, read a paper on

GUNSHOT INJURIES OF THE SPINE, WITH REPORT OF A CASE.

He referred in detail to a case of fracture of the spine due to a gunshot injury, resulting in recovery. He then quoted at length from a number of prominent authors on the subject of operative interference in these cases. He divided gunshot injuries of the spine into three classes: 1. those that simply fracture the arches; 2, those that invade the canal, crushing the cord and damaging the vertebra, and 3, those complicated by serious injury to abdominal or thoracic viscera. He then gave some particulars of cases referred to by various surgeons with the results, and stated that he had tabulated forty-nine cases treated since the aseptic era, of which twenty-four were subjected to operation, with eleven recoveries and thirteen deaths. The conclusions reached by Dr. Prewitt were: 1. That it is the duty of the surgeon to advise immediate operation in all cases of gunshot wound of the spine, provided the wound has involved the posterior or lateral parts of the spine at an accessible part, unless the condition of the patient is such as to indicate clearly that he is hopelessly crippled. 2. To wait to see whether nature is competent to restore the damage is to wait until irreparable damage has been done in many cases and rapid degenerative changes, meningitis and myelitis have resulted. The delay permits of the continuance of the conditions, the removal of which is the purpose of the operation. These considerations apply with greater force, if possible, in gunshot injuries than in others. 3. The presence of complications due to penetration of the great cavities and injury of the viscera will influence the question of operation, but not necessarily forbid it. At the end of the paper there was a very extensive tabulation of cases.

Dr. W. W. KEEN of Philadelphia, expressed his belief in operating for gunshot injuries of the spine unless the indications pointed to a total transverse lesion. He doubted very much the probability of such a lesion unless it was proved that the patellar reflexes were entirely absent. He stated that some years ago, when looking up the question of the surgery of the spine, he observed that there were very few cases reported of suturing the spinal cord, and in no case was it thought that good resulted. In general he was of the opinion that if there was not a transverse lesion, suturing was not advisable and he doubted its efficacy.

Dr. MAURICE H. RICHARDSON of Boston, referred to the difficulty of diagnosis in these cases as to the exact condition of the spinal cord and expressed himself as very undecided what to do when accidents happened to this region.

Dr. H. F. BURRELL of Boston, did not think it possible to

come to a proper recognition of these cases until the pathologic condition in the cord as the result of the injury was clearly understood and the only way to understand it was by opening up and examining, except in the case of shock, when this procedure would be contraindicated. He referred to the case of a woman whose spine was doubled on itself by jumping from a window, from which injury she died thirty-six hours later, after being completely paralyzed from the time it happened. At the autopsy there was no compression of the cord although red softening had already begun, thus proving that if any operative interference is to be attempted for the removal of a clot, bullet or fragment of bone it must be done immediately. Although the mortality will doubtless be very great there will be a certain number of cases terminate favorably. In 1894 he presented to the British Medical Association some statistics on this subject which he divided into those extending from 1864 to 1886 and those from 1887 to 1894. During the former period the cases had been treated by immediate rectification of the deformity by force with a percentage of eighteen recoveries out of one hundred cases. The second group was treated by immediate suspension followed by the use of plaster-of-Paris, with the result that 28 per cent recovered, an increase of 10 per cent.

Dr. N. B. CARSON of St. Louis agreed with Dr. Burrell that a certain number of cases would no doubt recover after operation. He mentioned a case of a man who was caught by the neck and pulled forward while trying to enter a low doorway riding on a load of hay. Complete dislocation of the spine resulted with loss of sensation and retention and paralysis of the bladder. Upon the patient consenting to an operation he was immediately suspended by the Sayre's suspension apparatus and dislocation was reduced. Immediately thereupon there was collapse and loss of consciousness. The man was at once lowered and after being well padded left alone. Later a plaster of Paris jacket was applied and an excellent recovery resulted.

Dr. P. S. CONNER spoke in favor of exposing the damaged part in order to ascertain the exact character of the injury and to remove anything that might be pressing upon the cord. He did not believe that the symptoms ordinarily clearly indicated the character of the lesion and although the mortality from operation would be heavy he considered that a moderate amount of gain was preferable to an excessive amount of loss.

Dr. F. S. DENNIS of New York referred to the publication from him, some time since, of a number of cases treated with the plaster-of-Paris jacket, in which excellent results followed. He strongly urged the ministration of large doses of the iodid of potash during the time the patient was wearing the plaster as he believed it had great advantage and benefit on the absorption of the clot.

Dr. CARSON again spoke on this paper and stated that he was not very much impressed with the results obtained by the use of the plaster-of-Paris jacket, especially if applied after inflammatory changes had taken place.

Dr. W. H. CARMALT said he should have no hesitation in operating in the case of gunshot wound in order to prevent infection. He quoted one case where operation was refused and the patient recovered after simply being treated by the application of the plaster-of-Paris jacket. A second case, where operation was also refused and in which practically the same symptoms were present was treated in the same way and died in three days so that he did not believe surgeons were at present in a position to formulate any rules on this subject.

Dr. BURRELL again discussed Dr. Prewitt's paper and commented upon the case reported by Drs. Carson and Carmalt. He believed that sometimes there is a reunion of the fibers of the cord by the formation of connective tissue, which is subsequently absorbed.

Dr. W. H. HALSTED of Baltimore, agreed with the previous speakers and stated that he had only had one successful case.

Dr. PREWITT closed the discussion by referring to the excellent work done by Drs. White and Burrell on this subject. In his opinion such fractures as those referred to by Dr. Carson should be called simple fractures, oftentimes resulting from a displacement of the body of the vertebra itself. It is quite possible for dislocations to cause pressure on the cord without there being any fracture, especially if the lamina be fractured. Gunshot wounds, he stated, are always compound and local, and he believed the great difficulty in determining what to do for these cases was the fact that one did not know the exact condition present, and this could only be ascertained by cutting down upon the cord. Seeing that most of the cases would die anyway, he did not think any harm could be done by opening up and disinfecting the wound. If the likelihood of meningitis can be lessened, the benefit of the doubt should certainly be given to the patient. He then referred to cases reported by

Cooper and especially to one reported to Hawley where the man lived for five and a half years after a gunshot injury, subsequently dying from irritation caused by the fragment of bone. Had these been removed the man would probably have lived many years longer. With regard to the complete severance of the cord he thought the condition of the case reported by Dr. Briggs pointed strongly in this direction as pain, sensation and motion immediately appeared after the suturing of the cord whereas all had been absent before. He did not believe in waiting several weeks before operating but was in favor of immediate interference.

He reported having seen good results in several cases from the application of the plaster of Paris jacket and quoted the statistics of Dr. Burrell in this connection. He would not urge operative interference where it was apparent that pressure was not being exerted upon the cord but he believed that in gunshot injuries one would almost always find spicules of bone and pieces of lead long after the accident. In conclusion he agreed with Erichsen that but little harm could be done by operation anyway and if a few cases could be rescued it was worth doing.

The following papers were read by title: "Nosology and Morphology of Tumors, True and False," by Dr. Souchon of New Orleans. "Radical Cure of Femoral Hernia in the Light of Recent Methods," by Dr. Rudolph Matas of New Orleans. "A Case of Fecal Communication," by Dr. Geo. R. Fowler of Brooklyn.

Dr. JAMES E. MOORE of Minneapolis, read a paper entitled

HYSTERIA FROM A SURGICAL STANDPOINT.

He said that hysteria is so frequently met with in surgical cases that the surgeon must always be on the alert or he will be guilty of grave errors in diagnosis and prognosis. Hysterical symptoms frequently develop as a post-operative complication. Rise of temperature following operation may be purely neurotic. He cited some cases. Persistent hiccough, cough, or emesis following an anesthetic may be hysterical. Cases of hysterical aphonia following an operation in an adult male. Phantom tumors mentioned. The surgeon shall be careful in operating upon or advising neurotic females in whom the subjective symptoms are out of all proportion to the objective, because they will often be willing to submit to grave surgical proceedings when their sufferings are purely imaginary. Such patients frequently derive morbid pleasure from an operation. These patients are better subjects for the osteopaths and Christian scientists than for the surgeon. The author cited a case in which the patient had had several operations performed and who was willing to submit to an operation for appendectomy although she had no appendicitis. Hysterical hyperesthesia, anesthesia, paresis and seemingly complete paralysis may be so mingled with real pathologic conditions as to mislead skilled diagnosticians. Patrick's method of diagnosing hysterical hyperesthesia or anesthesia by means of the shifting border of the affected area he found helpful in diagnosis. The surgeon meets with hysteria most frequently in joint and spine ailments. Hysterical joints are a close resemblance to diseased joints and should always be remembered by the surgeon to avoid mistakes in diagnosis and prognosis. The hysterical joint usually follows an injury. There is slight atrophy, no local rise of temperature or it may be subnormal; no marked swelling but may be slight puffiness; marked restriction of motion, but is voluntary in character and readily overcome when the patient's attention is directed to something. The muscular spasm is different in character and more pronounced than that from tuberculosis. The deformity is often exaggerated and often differs from that of disease. Hysterical joints are most common in hysterical persons, but may occur in persons with no such history. A hysterical patient may develop a tubercular joint. Prognosis in hysterical joints is good, organic changes rarely if ever present. Suggestion is a valuable means of treatment. Correction under anesthesia is recommended. Cutting operations are not necessary. Cord changes do not occur from hysteria. Hysterical spine is easily diagnosed because it does not resemble deformity from disease. A number of cases were reported illustrating hysteria as met with by the surgeon.

The following officers were elected for the coming year:

President, W. W. Keen of Philadelphia.
First Vice-president, A. Vanderveer of Albany.
Second Vice-president, C. H. Mastin.
Secretary, H. L. Burrell of Boston.
Recorder, DeForest Willard of Philadelphia.
Treasurer, G. R. Fowler of Brooklyn.
Delegate to the Association of American Physicians and Surgeons, Wm. H. Mastin; Alternate, F. H. Gerrish of Portland, Maine.

Place of next meeting, Chicago, Ill., at a date to be determined later.

Medical Association of Georgia.

Proceedings of the forty-ninth annual meeting, held at Cumberland Island, April 20, 21 and 22, 1898.

FIRST DAY—AFTERNOON SESSION.

The Association met at 2 P.M. in the Auditorium of the Georgia Teachers' Association, and in the absence of the president, Dr. James B. Morgan of Augusta, the meeting was called to order by the first vice president, Dr. L. G. HARDMAN of Harmony Grove.

Divine blessing was invoked by Dr. J. W. Duncan of Atlanta.

Col. R. E. PARK was then introduced and delivered an "Address of Welcome" on the part of the Cumberland Island Club.

Dr. J. A. BUTTS of Brunswick welcomed the Association on the part of the local profession.

The response to these addresses in behalf of the Association was made by Dr. Hardman.

Dr. J. G. HOPKINS of Thomasville read a paper entitled

A FEW CASES FROM MY NOTE-BOOK.

Case I was that of a man 30 years of age who complained of having "a chafe which would not heal." Upon examination the Doctor found two fistulas centrally located over the lower end of the sacrum, one inch apart, and about one-twelfth of an inch in diameter. He converted the two openings into one and found a bunch of curly blonde hair about two to two and a half inches long, and in amount sufficient to fill a No. 10 thimble. After scarification and cauterization he left the wound to heal by granulation. A month later the patient returned saying that the wound had never healed. On examination the cavity was found well filled with new tissue, but there were several small fistulous openings instead of the two, as before. From each of these openings he drew several strands of hair, similar to those first removed. He cut down again to the bone, drew a lot of hair out of the flesh from different directions and packed the wound. He again allowed the cavity to fill and the same result was obtained. He again cut down and resorted to the same procedure, and the wound is now open and the same condition exists. He said that a dermoid cyst was not a very uncommon thing, but the sex, situation and constant recurrence of the hair in this case rendered it rather unique.

Another case was that of a mulatto, aged 28 years. His personal history was good and he was never sick except with a slight attack of the influenza in December, 1896. He was seen first on Sept. 20, 1897; had had fever about twenty-four hours; temperature 102 degrees and pulse 128; had a few bullae on lips, face, wrists and shins. A diagnosis of pemphigus was made and quinin and arsenic treatment begun. Local applications of dry boracic acid were resorted to. The bullae appeared thick and fast, varying in dimensions from the size of a filbert to that of a walnut and required but a few hours to reach full growth. They were punctured at each visit, giving exit to the fluid contents at the most dependent point, leaving the cuticle otherwise intact for protection. In a few days almost the entire cuticle had been separated from the cutis. The scalp, palms, and the mucous membrane of the nose, mouth and throat were extensively involved. Deglutition was difficult and painful and liquid diet a necessity. The symptoms in this case were those of pain, itching and fever. The treatment, while in the hospital, was mercurial cathartics, followed by salines and liquor potassii arsenitis in increasing doses; also large doses of the sulphate of quinia. The local treatment consisted of alkaline baths and a paste compound of aristol, bismuth, oxid of zinc and vaselin. The patient was enveloped in absorbent cotton from head to foot, the same being held in place by roller bandages. His mouth and nose were kept clean with peroxid of hydrogen and he was subjected to formaldehyde fumigation. The skin remained pigmented for three months after. Patient was discharged cured, Oct. 27, 1897.

Dr. WILLIAM C. LYLE of Augusta followed with a paper entitled

THE IMPORTANCE OF CAREFUL CHEMIC ANALYSIS IN GASTRIC DISORDERS

In which he showed that the technique of chemic analysis of the gastric contents was by no means difficult, and that in the determination of a correct diagnosis it was of the utmost value. He said that the skill to obtain and analyze the contents of the stomach did not lie beyond the dexterity and ability which every physician ought to possess, and it certainly should be utilized, when we consider that the diagnoses of diseases of the stomach are based as much upon the results of our own investigations as upon the statements of the patients themselves. The author contented himself by referring to only a

few of the more important tests, tests requiring no apparatus nor reagents that the average practitioner does not possess. He first spoke of the test meal, then stomach contents, lactic acid, pepsin and absorbent tests, after which he reported cases, that had recently occurred in his practice, where a positive diagnosis would have been very difficult without frequent chemist tests. The first case was one of simple dilatation of the stomach; the second, round ulcer of the stomach and acute gastritis; the third, cancer of the pylorus; fourth, obstruction of the portal circulation due to cirrhosis of the liver, as shown by autopsy.

The next paper, entitled

GERMS OF HEALTH AND DISEASE.

Was read by Dr. J. W. DUNCAN of Atlanta.

The author said that much attention had been given to the germ theory of disease for a number of years, and much had been learned through patient and faithful bacteriologic research. Reference was made to the contributions of Dr. Heneage Gibbs, one of the foremost bacteriologists, and who for several years occupied the Chair of Bacteriology in the University of Michigan. While recognizing the existence of bacteria, and their possible influence, Dr. Gibbs denied their importance as a causative factor of disease. He conceded to Dr. Koch the discovery of the tubercle bacillus, and the bacillus of cholera, but he denies that in either instance has the etiologic influence been demonstrated. He denies, furthermore, that these pathogenic micro-organisms are always present in certain diseases. He declares that he has conducted hundreds of autopsies on consumptives without finding a trace of the bacillus of tuberculosis. He said: How can we most successfully limit the spread of contagious diseases? In the operating room extensive major operations are being done daily under aseptic and antiseptic regime, and notwithstanding the extensive field explored, not a microbe or bacterium can gain a foothold. Much is being done in private practice to limit the spread of the disease, but very much more should be done. The excreta from the sick, whether from the bowels, kidneys, lungs or skin, should be disinfected, and as soon as possible the house should be fumigated. It has been said that "cleanliness is next to Godliness," and therefore our sanitary boards should be vigilant in keeping everything clean, that is, in their province. There should be more attention given to the matter of the milk we drink, and that there be no sources of contagion from them. Meats and vegetables demand investigation. Each individual should observe the laws of sanitation and hygiene relative to his own person and premises. By so doing he will be the better able to resist contagion should he be exposed. He then dwelt upon antitoxins, the results from which he considers far from satisfactory and spoke of the use of antiseptics, what they were, and how they acted.

Dr. W. Z. HOLLIDAY of Augusta, said that he had recently treated a well advanced case of consumption, where a microscopic examination was first made. The expectoration from this patient consisted of lumps of sticky mucus in which one would expect to find colonies of so-called specific germ of the disease, but repeated microscopic examinations failed to demonstrate the presence of the tubercle bacillus.

Dr. DUNCAN in closing the discussion, said that tubercle bacilli were frequently found during the incipient stage of tuberculosis, but that later in the disease, although the expectoration was carefully examined none were to be found, while still later tubercle bacilli might be found in the sputum in abundance.

Dr. W. H. ELLIOTT of Savannah, read a paper entitled

MUSHROOMS—A FOOD AND A POISON.

He stated that the number of mushroom-eaters in this country was steadily growing larger, and it was incumbent upon physicians to know how to recognize and treat cases of mushroom poisoning. Mushrooms belong to that order of plants known botanically as fungi. There are many thousand species. By far the larger number are microscopic, such as the mildew, the smut on grain, and the mold that forms on cooked fruit, etc. The larger forms of fungi are known indifferently as toadstools or mushrooms. These number about one thousand species. While mushrooms grow in many different forms, the commonest and best known is the campestris, or mushroom of commerce. This belongs to the class of agarics, or gilled mushrooms. Dr. Elliott then described the structure of an agaric. He spoke of three classes of mushrooms ordinarily used for food; agarics, boleti and puff-balls, and described their structures. He said that in the United States food was so abundant and mushrooms so little known that tons of delicious food were allowed to go to waste for the want of the gastering. Their use in this country was limited to a few botanists and others, members of mushroom clubs of Boston, New York,

Philadelphia and Washington. In Europe mushrooms were in general use as food. They were gathered in the woods and fields, regularly sold in the markets, and in Paris miles of cellars were maintained for the artificial cultivation of the mushroom of commerce. He had in the past two seasons tried about one hundred varieties of mushrooms without any unpleasant consequences. To the beginner he would say, avoid all mushrooms with a cup or the suggestion of a cup, especially if the mushroom has white gills. Reject all that are not perfectly fresh, or that are worm-eaten. In short, mushrooms should be gathered with care and studied well.

FIRST DAY—EVENING SESSION.

This session was largely taken up with the consideration of routine and miscellaneous business.

SECOND DAY—MORNING SESSION.

Dr. HOWARD J. WILLIAMS of Macon, read a paper entitled

A SUPERNUMERARY CERVICAL RIB; A DECEPTION OF SKIAGRAPHY.

The author said that while the discovery of Roentgen was a material advance in surgical diagnosis, it was not an infallible aid. Mistakes in interpretation could lead to mistakes in operating, and its value as medicolegal evidence was doubtful. Three times during the past year the speaker had been misled by X ray photography; twice into performing useless operations for lesions supposed to be dependent upon apparent bone injury, and in one case a supposed tumor proved to be an anomalous rib. Fortunately, the operation was necessary, and the results were as satisfactory as they would have been had a tumor existed. The speaker thought that either of the two photographs of the bone injury exhibited in a court room would have been damaging evidence in a malpractice suit, had not the operation disclosed the fallacy of the skiagraph. Dr. Williams then detailed the case of supernumerary cervical rib. In looking up the literature of anomalous ribs he found that Quain described an occasional supernumerary rib which sprang from the body and transverse process outside of a vertebral arterial foramen. This was, however, a false rib, having no distal attachment. He could not, in the books to which he had access, find any description of a supernumerary rib corresponding to the one he presented, that is, a rudimentary rib springing from the sixth cervical vertebra with a single attachment, a complete arch, and a long insertion on the first rib. The patient pursued the usual normal course after aseptic operations, had primary union and was restored to health without pain or interference with the functions of the parts involved.

Dr. SAMUEL LLOYD of New York, said the use of the X ray in medicolegal work without careful preparation for that work on the part of the surgeon, would do great harm. To leave a skiagraph to a single individual who might be interested in the case and go into court would be a grave error, for the deformity might be accentuated very decidedly by placing the tube in an improper position, and consequently in every case that has to appear in court the X ray picture should be taken before witnesses who can swear to the position of the photographic plate, the position of the patient on the plate, and the position of the tube, and at the same time, who can swear to the distance at which the tube was placed from the patient, so that allowances may be made for any distortion that may appear in the picture, and as far as possible to avoid distortion.

Dr. T. S. HOPKINS of Thomasville, read a paper entitled

DISLOCATION OF THE SIXTH AND SEVENTH CERVICAL VERTEBRÆ, WITH GENERAL PARALYSIS.

On March 3, 1897, Col. H. sustained an injury, the results of which made the case not only interesting, but remarkable. The history of the accident is as follows: While riding on a crank-car, the car collided with a wood cart. The shafts of the wood cart were elevated and one of them struck the patient on the forehead, knocking him over backward, his neck falling across a thin iron bar. He was lifted from this position unconscious. At the end of an hour consciousness was restored. He was taken to the house of a friend, placed in bed, and medical aid called. Diagnosis of shock was made. Next morning a consultation was held, and the condition of the patient pronounced serious. On lifting him it was discovered that his head would fall over his chest. It was also found that with the exception of the respiratory muscles, every muscle below the cervical part was paralyzed. The patient was then transferred to a Savannah hospital, where he received the best medical skill, and three or four days after admission the neck trouble suddenly disappeared. The neck became the only paralyzed part of the patient. The diagnosis made by Dr. Boyd, the surgeon in charge, was dislocation of the sixth and seventh cervical vertebrae, with crushing of the cord, and spontaneous reduction by muscular contraction. After three months of

hospital treatment the patient was sent home as a hopeless case, the only improvement being a slight ability to move the right leg.

During the months of June and July last, Dr. Hopkins frequently visited and examined the patient. He was on a very restricted diet, and there was much muscular waste and atrophy. He feared the patient would never walk again. As he knew of no curative plaster to apply to a crushed cord, he advised that the restricted diet be abandoned, that physic be thrown to the dogs, and he be allowed to indulge in every article of food he could relish. This advice was carried out. Very soon the patient's dyspepsia disappeared and his appetite and digestion improved. He had beef steak, ham, eggs, oysters, shrimps, crabs, fish, and every variety of vegetables and fruits, and under this treatment gained flesh and strength. When he left him, about the first of last October, he had entire control of the right leg and arm. The index and middle fingers of the right hand were contracted. He could lift the left arm and hold it in any position except a perpendicular one, but the hand fell over on the wrist. This was not the result of contraction of the flexors, but the powerless condition of the extensor muscles. The bed sores had healed. The catheter and syringe which he had used for months were dispensed with, being no longer needed. The left leg was still paralyzed. Although the patellar reflex and motor power were absent in this leg, sensory power was present. Time and again he would say to the patient: "Lift this leg; you can if you will," but he always declared that it was impossible.

Having observed, in cases of locomotor ataxia, that though the patient could hobble about with his eyes open, when he closed them he would fall, Dr. Hopkins determined to aid the muscular power with the visual power. He therefore uncovered the paralyzed limb so that the patient could see it, and commanded him to lift it, and instantly the leg was lifted, but fell again. Some two weeks later the patient's then condition was compared with his condition six months prior, and there was found to be decided improvement in the case. He was able to draw up both his legs, and extend them with perfect ease; has gained flesh and strength, and is looking much better. If he continues to improve in the next six months as he has during the past six months, he will be able to walk.

Dr. Hopkins asked whether anyone could tell how it was that while life had been restored to the dead limbs, the bowels and bladder, without any evidences of wound or disease of the cord below the seventh cervical vertebra, that power of locomotion was still absent. The case had been submitted to a neurologist and a pathologist for opinion. Neither of them would believe that a dislocation of the sixth and seventh cervical vertebra could produce paralysis of the upper extremities. He differed with them, and is consoled with the fact that the diagnosis of Dr. Boyd was endorsed by such men as Carpenter and Gross. During the patient's long suffering his intellect has never been impaired. He swore from the first, and still swears, that he will not die, and will before long be restored to his normal condition. Dr. Hopkins is now inclined to endorse his prognosis and, if verified, the case will be one without a parallel.

Dr. ELLIOTT of Savannah rose to answer the question in regard to paralysis of the upper extremities in such cases. He said many years ago he attended a woman who was shot directly from behind, by a pistol, in the fifth cervical vertebra. She lived a little less than five days after being shot, and was paralyzed from the site of the injury down to the bottom of the feet. She could move neither arms nor legs, nor anything else but her head.

Dr. J. W. DUNCAN of Atlanta, said that some years since he attended a negro man who had received an injury by a post falling upon him while taking down the scaffolding of a new church. He was struck on the back of the head, causing partial dislocation of the fourth and fifth cervical vertebra, followed by complete paralysis of the upper and lower extremities. The man could talk, and was rational. He lived about thirteen days. At the autopsy Dr. Duncan removed a portion of the cord involved in the partial dislocation and found that it had undergone degeneration and softening, and was very much like an ordinary abscess.

Dr. SAMUEL LLOYD of New York, said that some ten years ago he published the statistics of over two hundred cases of operations upon the spine for injuries, and for Pott's disease, and since then he had operated on a considerable number of cases. In Dr. Hopkins' case he thought that one part of the diagnosis must have been in error, and that was in regard to the crushing of the cord. A patient who has a crushed cord never recovers. The probabilities were that the cord was compressed, and from the progress of the case Dr. Lloyd suspected that the compression was a hemorrhage, and the absorp-

tion of the clot accounted for the recurrent power in the cord itself. Most assuredly, there was no injury at the time of the receipt of the trauma that destroyed the elements of the cord itself, for had it been the patient would have had an ascending and descending myelitis, and a consequent increase in the area of paralysis. Last summer he saw a patient who was shot four years ago, and received an injury to the right lamina of the seventh dorsal, a fracture of the spine of the eighth dorsal, a fracture of the left lamina of the ninth dorsal, and a fracture of the articular process of the tenth. The man had complete paraplegia below the segment of the cord injured. He had, however, increased reflexes, and particularly on one side, so that he had to travel around with the leg strapped up. If he let the right leg dangle it would throw him over his crutches as soon as anything touched him. He had compression by callus over the right lamina, and it was thought he would probably get well. The lamina of the fourth vertebra was taken out, after which adduction and abduction, and the reflexes, were normal.

Dr. HUNTER P. COOPER of Atlanta, read a paper entitled

A REPORT OF SURGICAL CASES.

The first case was that of a stone impacted in the deep membranous urethra of a child. There were no renal calculi nor any colic. There was retention of urine for thirty six hours. The author made a eupubic cystotomy, and then a perineal section, removing by the latter a stone, the size of a small bean, which completely occluded the caliber of the urethra. Recovery ensued. The interesting point in this case was the rarity of it. The object of the double operation was to secure efficient drainage, and to satisfy the essayist that there was no stone left behind in the bladder. The after-course of the case justified the double operation, in that there was no untoward symptoms.

The second case was one of nephrotomy for a stone in the kidney, the patient being a member of the Association.

The third case was one of crushing wound of the lower end of the femur, received in a railroad accident in October, 1897. Amputation of the lower third of the thigh was done by one of the surgeons on the Georgia Railroad, immediately after the accident, followed by infection of the wound, profound and intense septicemia, necessitating the reopening of the whole wound, and the end of the bone projected between the flap, so that when the patient was brought to Dr. Cooper on the 10th of last December, the temperature was 103 degrees and the pulse 140. From the lower end of the stump to Poupert's ligament there was a large abscess necessitating operation under ether, and a pint of pus was evacuated. The patient did well for ten days, and then it was found that the granulations were in such condition that the lower end of the femur could be safely removed. Two inches of the lower end of the femur were removed. Later, large granulating masses appeared in the wound, which were found to contain bone, a microscopic examination of which revealed the development of osteosarcoma at the lower end of the femur. On January 18, Wyeth's bloodless hip-joint amputation was done. There was severe shock from operation, but recovery followed.

The fourth case was one of wry-neck, with open section of the sterno-cleido-mastoid muscle throughout its whole extent an inch and a half above the clavicle.

The fifth case was one of keloid on the back of the head and neck.

Dr. DUNBAR ROY of Atlanta, contributed a paper on

PERITONSILLAR ABSCESS.

The author said that the reading of this paper was more for the purpose of precipitating a discussion than an effort to add any new ideas upon the subject. A great deal had been written by laryngologists concerning the cause, symptoms and treatment of acute tonsillitis and chronically hypertrophied tonsils, but very little could be found concerning the manifestations of peritonsillar abscess, and even the various textbooks dismissed this practical subject with a few words. He quoted from the writings of Ingals, Lennox Browne, Max Thorner, C. E. Bean, showing that these writers differed materially as to the pathology and morbid anatomy of this affection. He then dwelt upon the anatomy of the affection. He had never seen a peritonsillar abscess the result of infection through the tonsillar lacuna but what had its seat posterior to the tonsil. Abscesses which occurred anteriorly, in his experience, were the result of suppurative processes from the posterior portion of the alveolar process of the lower or upper jaw on the same side. He had seen abscesses in the front of the tonsil, of most painful character, which were the result of a pathologic process in the last molar tooth. As to the cause of these peritonsillar abscesses, it is held by some authors that they are always the result of a previous tonsillitis. In the light of

our present knowledge, there could be no doubt as to the bacterial origin of this affection. Most writers hold that peritonsillar and tonsillar abscesses are more common in children than in adults, and yet the author's experience is just the opposite. With the exception of two cases only, all of his cases have been in adults.

Treatment.—Can the abscess be aborted? The author's views are that if the patient is not one of those predisposed to peritonsillar abscess, and the inflammation in the tonsil has started upon its surface, we may in some cases abort the abscess, but in the large majority of cases, we are powerless to stay its course. The treatment of tonsillitis and peritonsillar abscess naturally divided itself into the medicinal and surgical. On medicinal treatment the author quotes Ingale, who says: "Early in the attack the disease may be aborted, as in acute tonsillitis, in about one case out of four, by the application to the inflamed glands, once or twice daily, of a 60 grain solution of nitrate of silver, two or three applications usually being sufficient." Dr. Roy spoke in the very highest terms of this treatment in all forms of acute tonsillitis. He agrees with Ingals that guaiac is unsatisfactory. He is also in full accord with Max Thorne, who recommends the administration of large doses of salol in addition to local applications, but who says it is much better to begin early with hot fomentations around the neck, hot gargles, and hot inhalations in order to hasten suppuration, and in this way to shorten the duration of the disease. As to the surgical treatment of peritonsillar abscess, it is governed by a rule which the author has adopted in the treatment of all patients, and that is, adapting the treatment to the individual case, and not the patient to the treatment. It was the extreme of fallacy for physicians to have fixed rules for the management of all cases. It might be highly proper in the case of a big, strong lymphatic working-man to pick up a bistoury and plunge it into the abscess, press its sides, and evacuate the same thoroughly, and he perhaps would hardly flinch, but to undertake the same procedure in the case of a highly nervous and sensitive woman, was not right. Besides, the formation of a peritonsillar abscess was not near so painful in some patients as in some others and, therefore, did not require such active surgical measures. As the majority of abscesses follow from tonsillitis, his efforts are always to abort the inflammation, and this he accomplishes, if at all, by the administration of a good dose of calomel, followed by a saline purge. The tonsil and surrounding pillars are painted thoroughly with a 60 grain solution of nitrate of silver, repeated once daily. He starts early with hot gargles of vinegar and hot water, and then hot fermentations are applied externally. Salol and phenacetin always make the patient feel more comfortable, and for this reason alone he prescribes them. His experience with lactophenin has not been satisfactory. The author favors surgical measures when medical means fail.

SECOND DAY—AFTERNOON SESSION.

Dr. WILLIS F. WESTMORELAND of Atlanta, reported twenty-nine successful cases of tracheotomy for foreign bodies in the air passages, and exhibited specimens.

Dr. M. F. CARSON of Griffin, followed with a paper entitled THE CONDITION OF IMPERFECT SEPTUM BETWEEN THE MOUTH AND NASOPHARYNX, USUALLY TERMED CLEFT PALATE,

in which he advocated early operation for the closure of the cleft.

Dr. J. H. SHORTER of Macon, read a paper on

SUPPURATIVE DISEASES OF THE MIDDLE EAR, AND THEIR SEQUELÆ.

He said that otitis media purulenta may be acute or chronic, the latter often a sequence of the first. The former, as is the case in most affections, yields the more promptly to treatment, with altogether a better prognosis both as to cure of the suppurative process and restoration of the function in the diseased ear, while, at the same time, the risk of serious secondary complications was much less. The exciting cause of an otitis media acuta may be an influenza and acute pharyngitis, improper use of the nasal douche, and sea bathing, diphtheria, etc. It was particularly liable to occur in the course of exanthemata, especially scarlatina, and sometimes is a complication of the other fevers, as pneumonia and typhoid. It may be traumatic, as from injury to the drumhead or injection of irritant liquids through the Eustachian tube, a mode of treatment for chronic middle ear catarrh favored by some men of eminence, but which he has quite abandoned on account of having seen so many cases of violent middle ear reaction, and even suppuration set up by it, not alone in his personal practice, but in that of other surgeons, some of them of noted skill and expe-

rience. In New York there were always a large number of acute middle ear inflammations during the season of surf bathing. This he attributes, not as he first thought, to the impact of the sea waves on the side of the head, or the canal over the drum-membrane itself, but to the spasm accompanying the sneezing, swallowing and gagging caused by water entering the nostril, driving the liquid up the Eustachian tubes into the tympanum. Among traumatic causes may be mentioned picking the ear with a sharp instrument for the removal of wax or a supposed foreign body. Not a few times he had known the drumhead to be lacerated by this foolish performance, and had a case on record where most of the membrane was removed, and with it the malleus and incus, done by a machinist who used a long awl in attempting to remove a supposed foreign body from the ear of a fellow workman. Predisposing causes are important factors in otitis media, both acute and chronic, and chief among them being obstruction in the nasal cavities or nasopharynx, adenoid or lymphoid tissue in the fold of the pharynx, hypertrophied faucial or pharyngeal tonsil, etc. The author then dwelt at length upon the treatment he carried out in dealing with these cases.

Dr. JAMES M. CRAWFORD of Atlanta, read a paper on

TONSILLOTOMY: WHEN AND HOW TO MAKE IT.

He said that tonsillotomy should be resorted to when the tonsils extend much beyond the pillars, not waiting until they touch each other, especially when oral catarrh exists. It is indicated even when the tonsil is slightly hypertrophied, if the lacunæ are inclined to inflammation from collection of caseous secretions. Shaving the tonsil destroys these lacunæ, thereby preventing frequent and painful inflammation. Not even the most timid operator would hesitate to make the operation when the tonsils are so large as to reach the uvula, thereby making it laborious to breathe, especially when the patient is asleep, and these diseased conditions often prevent respiration. Below the age of 15 years the tonsil is usually soft, and when cut with the tonsillotome the cut edges are more or less mashed or pressed together, thereby stopping the hemorrhage. In older persons, however, the tonsil is more fibrous. The walls of the cut vessels are pulled apart, as it were, by the firmness of the tonsil itself. He would not hesitate to make the operation when it was needed, even in the oldest. Fortunately, after a certain age the tonsils atrophy, and require to be removed rarely. Fewer cases of hemorrhage occur when the operation is made with the tonsillotome instead of the vulsellum forceps and bistoury. When using the forceps and bistoury the operator is apt to pull the tonsil too much with his forceps. In such a case he knows not where he is cutting. On completing the operation and looking into the mouth of the patient, he sees a sulcus where a portion of the tonsil should have been left. A sulcus, besides endangering the life of a patient by hemorrhage, is a source of constant annoyance in that it is a lodging-place for food. The author prefers Mackenzie's tonsillotome, or some of its modifications, to all others, for the reason that it is more simple, more easily managed, and less cumbersome. There need be no fear of the tonsil falling into the larynx, as it nearly always adheres to the instrument. Where it does not adhere to the instrument it falls into the mouth and is expelled. By applying a little cocaine, say a 6 per cent. solution, to the tonsils and fauces, sensibility of the throat is allayed, which is a great aid in the operation. While acting as assistant to Dr. Calhoun, he could recall five or six cases of frightful hemorrhages from tonsillotomy made by him with the knife and forceps. In each case the hemorrhage was stopped by Dr. Crawford putting a wet sponge or pledget of cotton on the cut surface and applying pressure. In each of these cases a sulcus existed, making it impossible for him to see the bleeding artery, and forcing him to resort to the only safe method in such cases, namely, pressure. The first time he used this method for controlling hemorrhage was in the fall of 1889. The two means for arresting hemorrhage in connection with tonsillotomy were the cautery, when the bleeding point could be seen, and in other cases the application of pressure.

Dr. W. Z. HOLLIDAY of Zugusta read a paper on "The Use of Ethyl Chlorid as a Local Anesthetic," in which he recommended this agent very highly for local anesthesia.

Dr. R. M. HARBIN had used ethyl chlorid and agreed with the author as to its efficacy. In selected cases it was an ideal local anesthetic.

Dr. J. G. HOPKINS asked as to the danger in handling the tubes, to which Dr. Holliday replied that there was very little danger from explosion if the physician was careful.

Dr. GRAHAM of Savannah had used with satisfaction the combined method of anesthesia, namely, ethyl chlorid and the infiltration method of Schleich.

THIRD DAY—MORNING SESSION.

Dr. J. T. Ross of Macon reported an interesting case of

OSSIFIC AND CALCIFIED OVARIAN FIBROMA

And exhibited the specimen. The specimen had very much the appearance of a fetal head. On one side a portion of the broad ligament, the Fallopian tube and ovary were seen. Almost all, if not all, of the fibroid enlargement was encrusted by an osseous deposit about one-sixteenth of an inch in diameter. The interior of the tumor was more firm and studded with calcareous deposits. Striae could be seen running down into the tumor from that portion of the ovary which formed the growth. Authorities are agreed that only 3 to 5 per cent. of all tumors of the ovaries are solid, and that a fibroid of the ovary is very rare. The condition presented in the case of Dr. Ross was still more rare. In fact, the speaker does not remember to have seen a record of an ovary which had undergone both osseous and calcareous degeneration.

Dr. K. P. MOORE of Macon read a paper entitled "A Very Interesting and Unusual Monstrosity in the Form of Twins," and exhibited the fetus.

Dr. E. R. CORSON of Savannah contributed a paper, "A Rare Form of Bone Atrophy Following an Ununited Fracture, as Seen by the X-ray."

Dr. J. I. GRIFFITH of Danielsville read a paper on

PUERPERAL ECLAMPSIA AND SOME PROBABLE CAUSES OF IT.

As to its etiology, the author quoted from Hare's work on "Therapeutics." He said that in order to arrive at an intelligent treatment there must be a clear understanding of the condition the physician is called upon to treat. The treatment should be classified as preventive and curative. The preventive may be subdivided into medicinal and hygienic, and the curative into medicinal and obstetric. These forms of treatment were then dwelt upon at some length. The author reported four cases. Some probable causes of eclampsia he mentioned, as albuminuria, toxemia, uremia, pyelitis and pyelonephritis. He thinks albumin is one of the causes of puerperal eclampsia, for it is found in the urine of pregnant women.

Dr. GEORGE H. NOBLE of Atlanta made some remarks on

ALCOHOLIC IRRIGATION IN PUERPERAL SEPSIS.

He pointed out the difference between the ordinary method of removing the secundines with douches, and the alcoholic treatment. He said that the alcoholic treatment was gradually forcing itself upon the profession. When his attention was first called to it he had little or no confidence in it, for the reason that he did not believe in the antiseptic properties of alcohol, but the more he studied it the greater seemed its need of application in certain directions. The successful treatment of puerperal infection depended upon the selection of cases. The practitioner who failed to properly select his cases and properly apply treatment would be the man who would lose patients. No treatment applied to the cavity of the uterus could be expected to save a case of puerperal infection that had gone beyond the endometrium to any extent. Therefore it was necessary to exclude diseases of the appendages, as pus tubes, abscesses, etc. The treatment of the cavity of the uterus, where there was a pus collection in the appendages, was futile. Again, the practitioner might think the appendages were absolutely healthy, that there was no infection in the uterine cavity that could be detected, and yet the patient was in a hopeless condition, whereas the trouble might be an abscess in the uterus proper, or its parenchymatous structure. The practitioner should bear in mind that if he has a case in which the appendages and peritoneum are not involved, and in which there is no material discharge from the cavity of the uterus, where the uterus is shrunken in size, the os non-patulous, he is likely to have uterine abscess, but it is a rare condition. There may be one abscess or two. He had previously reported four such cases in which he made an incision into the abscess, curetted, cauterized and drained through the abdominal cavity. He cited an illustrative case, the woman having miscarried the day before she was admitted to the hospital, particles of placenta remaining. When admitted the pulse was 149 and temperature 102.1 degrees. The uterus was thoroughly curetted and cleansed. The temperature fell after curetting. The pulse dropped in the afternoon, after the curettement, to 136, and the temperature to 100.4 degrees. The next morning it was 100.3 degrees, the pulse remaining the same. On the third day the temperature arose in spite of careful irrigation in careful hands. He then instructed the house surgeon that if the temperature rose to 103 degrees to discontinue the other treatment and put the patient upon alcoholic irrigation. The next morning the temperature rose to 103 degrees and after alcohol irrigation it fell to 100.3 degrees. The course of the pulse and temperature then was steadily downward. At the end of

eight days the patient was completely relieved. In this case there was a mixed infection, there being streptococci and diplococci found in the secretions. He said that alcoholic irrigation could be done by the general practitioner. The practitioner should use a rubber catheter thoroughly sterilized; take two yards of small gauze, the width of the finger, stitch it to the end of the catheter, introduce it carefully into the uterus, after it is cleansed, and loosely insert the gauze around it. The object of the gauze is to hold the alcohol. The alcohol is renewed through the end of the catheter, at variable intervals. Alcohol possesses considerable antiseptic properties, and has some inhibitory effect upon the spores of the virulent streptococci. Alcohol acts more powerfully where there is a good deal of water in the tissues. He believes it is the simplest method for treating puerperal infection confined to the cavity of the uterus. It must be remembered, however, that all local treatment must be confined to those cases in which the infection is limited to the uterine cavity.

Dr. W. E. FITCH of Savannah, contributed a paper on

TIGHT LACING—ITS RELATION TO UTERINE DEVELOPMENT AND THE DISEASES OF THE FEMALE ORGANS OF GENERATION

In which he called attention to the evil effects of tight lacing. The subject is of special interest to the practitioner as well as to the gynecologist, while to the race it is of serious importance. He thought the importance of the subject as an etiologic factor in diseases of the pelvic organs had been lost sight of in the mad rush in scientific research. Tight lacing, in his opinion, is not the only cause of maldevelopment of the uterus and accessory organs, causing diseased conditions, but one of the chief factors. He then reviewed the anatomy of the female pelvis. The corset is so constructed that when worn it exerts its greatest influence, pressure, from above the brim of the pelvis downward, constricting the abdominal walls, the lower part of the thorax, and pushing inward the costal cartilages and often the seventh and eighth overlapping. The greatest constriction occurs in the immediate neighborhood of the stomach, which, when distended, as after a hearty meal, produces the hour-glass stomach found at times in this class of patients. Compression is so great in most cases as to interfere with the normal peristaltic action of the intestines, thereby producing constipation. Compression in any part interferes with physiologic functions, and therefore the author arrived at the following conclusions:

1. The normal breathing of woman is like that of man, abdominal. Tight lacing changes the type to costal.
2. The pelvic organs normally make a considerable excursion with each respiration. Tight lacing in the upright position checks this motion almost entirely.
3. Sitting or leaning forward lessens intra-abdominal pressure. Tight lacing in these positions greatly increases intra-abdominal pressure.
4. The uterus is displaced downward by tight lacing from one to two and a half inches. The pelvic floor is bulged downward and the circulation rendered sluggish.
5. Uterine development is greatest from the twelfth to sixteenth years. Tight lacing is usually commenced at this, the period of the beginning of uterine development.

Tight lacing produces maldevelopment and displacement of the uterine organs and appendages. Amenorrhea is frequently the result of a poorly developed mucosa and its adnexa, together with faultily developed ovaries, a condition which if neglected, often leads to atrophy or congestion with long continued profuse flow. Dysmenorrhea is a condition which the author thinks is mainly due to maldevelopment of both the uterine appendages and the nervous system, also the muscular and cellular tissues, rendering them inadequate to their physiologic requirements. He said the only benefit obtained in the treatment of pelvic disorders with electricity is mainly due to its efficacy as an aid to more completely develop the much abused organs. All women who have practiced tight lacing complain of pain on removing the corset, this pain being due to the effort of the organs to assume their normal position.

Dr. J. L. HERS of Savannah, read a paper on "Malarial Asthenopia."

Dr. A. A. DAVIDSON of Augusta, read a paper on

HYSTERIA.

Hysteria, he said, is a disease wherein the emotional is in the ascendancy over the volitional, and characterized by marked and marvelous expressions of the propensities of the idiosyncrasy of the person affected, and is not hysteria necessarily because of any abnormal condition of the uterus, but a manifestation of a morbid and inco-ordinate activity of brain and nerve forces, volition being subordinated, characterized by symptoms motor, sensory and sympathetic, abnormal in nature. In expression it frequently simulates symptoms of various path-

ologic or diseased states, such as hyperesthesia, anesthesia, paralysis, convulsions, general or local suspension of functions, secretory and excretory, etc. The causes of this condition are predisposing and immediate or exciting. Hereditary stands among the first of the former. Family history of phthisic, strumous or neurotic antecedents may confidently be sought; many conditions of unsatisfied nature, long mental worry and physical strain and protracted suspense. Hysterical attacks tell upon the constitution. General muscular spasms are common in women who are the subjects of hysteria, less so in boys, rarely in men. A comatose state is not infrequently met with in them.

In the treatment of hysteria the thing of first importance is to obtain the confidence of the patient that his or her symptoms have been carefully sought out and weighed, that the promise of complete recovery may be held out as the result of careful study of the case, else little can be effected. In seeking the mode of management of this disorder we look away from drugs except in case of complicating intercurrent diseases. This is the rule and principle, but there arise conditions at times which must be met by the energetic use of active medicinal agents. One can not in every instance douche a pail of ice-water in the face of a patient if convulsions be present, though they be hysterical. The patient is a lady of social standing, of integrity and of delicate constitution; what is to be done? Power of moral suasion is not applicable by reason of the patient being in a semicomatose, if not pseudocomatose state, and will not be thus reached. Eminent writers would eschew such antispasmodics as bromids or chloral. Experience leads him to the conclusion that where sleep can be induced and maintained for some hours, a great advantage is gained. This can be effected by using chloroform to offset the paroxysm, continuing the sleep by use of chloral per rectum. The subject wants to be taking medicine and so reconstructives, tonics, etc., may very well be administered, since malnutrition, debility and anemia are favorable to the development and aggravation of hysterical symptoms.

A plan of treatment given by the author is that adopted by Dr. Weir Mitchell of Philadelphia, introduced into this country by Dr. Playfair, which consists of complete isolation of the patient and maintenance in bed, milk being given in increasing quantities. Massage is used in lieu of exercise; brilliant results have thus been secured. However the plan is rarely practicable. If it be impossible to place the patient among non-apprehensive and unsympathetic attendants, for the patient's sake and theirs, the family or those immediately interested should be acquainted with the true condition and educated to deal intelligently with hysterical attacks and phases. Parents should know what their impressionable children read; unlimited open air exercise should be encouraged. The mind should be engaged and kept off the imagined condition of self. The cardinal motive in treatment should be to so environ the patient as to call forth no expressions of an emotional nature, but rather conduce to exercise of reason and will.

INDICATIONS FOR AND ANTISEPTIC TECHNIQUE OF UTERINE DRAINAGE AFTER LABOR AND ABORTION

was the title of a paper by Dr. R. R. KIME of Atlanta. The author stated that when it is considered that at least 30 to 50 per cent. of diseases of women are traceable directly or indirectly to injuries or accidents during or after labor and abortions; that fully one-half of that number were due to infection in some one of its various forms, no apology is needed for presenting this subject. Some use antepartum douches, some postpartum douches, others condemn both. Some use antiseptic methods of prevention, some aseptic methods, others none whatever. Some advise washing out the uterus with strong antiseptics in puerperal infection, some use weak antiseptic solutions, others condemn the use of any. Some advise curetting the uterus in all varieties of infection, some curette only in putrid infection, others condemn the curette in all cases. Some advise abdominal section in severe cases, some perform hysterectomy, others condemn such operative measures and resort to vaginal drainage by incision as a life-saving measure. Some advise stimulants in large quantities, some depend upon strychnia, quinin and nourishment, while others kill their patients with the coal tar group of antipyretics. Some use the serum treatment, some the nucleins, others fail to get good results from either. Some administer opiates in full doses, some advise ealines, while the author favors elimination and drainage. Happy is the man that can judiciously select and apply to each individual case such treatment as will not only save life, but conserve the generative organs for future physiological functions.

In the treatment of puerperal infection, the practitioner must consider the anatomic relations and physiologic functions

of the female generative organ. The author does not believe that all cases of puerperal infection are due to contamination by physician or nurse, nor that the physician can always prevent such infection. We have sufficient clinical evidence to prove that where a uterus fails to properly drain itself, remaining large and flabby, a blood clot, portions of placenta, or a cotyledon is retained, infection occurs from putrefaction and absorption of uterine contents. Such cases are usually sapremia or putrid infection, but may be a mixed or true septic infection, due to the presence of septic germs in the genital tract previous to confinement. In cases of septic infection the author believes that the curette and gauze tampon have killed more patients than they have saved. When an active puerperal septic condition exists long enough to produce constitutional and local symptoms and signs sufficient to establish a diagnosis, the curette can not reach the diseased parts on account of the germs having extended beyond the endometrium into the uterine walls, blood vessels and lymphatics, and in rapid septic cases has extended so far that even hysterectomy is not justifiable in but few instances. He cares not if small portions of adherent placenta or cotyledon be present, efficient drainage will eliminate the toxins sufficient to wait for nature to separate these structures far more efficiently than the curette, when they can easily be removed by forceps without traumatism of the parts and with greater safety to the patient. The gauze tampon should never be used in a puerperal septic uterus except to check hemorrhage. So far as the present treatment is concerned, he considers uterine and alimentary drainage and elimination the most potent factors at our command. Uterine drainage is secured by use of drainage tubes and strips of gauze or wicking. The tube should be removed and uterus irrigated once or twice in twenty-four hours in severe cases, being governed by pulse and temperature. If they rise it is an indication for irrigation or that the drainage is obstructed.

As to drainage in cases of incomplete abortion, there are different conditions to deal with. The author limits the term abortion to interruption of gestation any time prior to the complete formation of placenta. At least 90 cent. or more of cases of infection occurring during or after abortion are putrid infection, hence easier controlled and with less demand for drainage. If an active septic infection occurs, then drainage is demanded even in cases of abortion. The dangers and contraindications to the use of the curette and tampon in septic cases increase in proportion to the advance in pregnancy and the increase in size and vascularity of the pelvic organs. While the author advocates an antiseptic gauze uterine tampon after curetting the uterus in cases of abortion, it is to act as a surgical dressing, prevent further infection, check hemorrhage, stimulate uterine contractions, and not for the purpose of drainage. The tampon should be removed in twenty-four to forty-eight hours and not repeated. If after gauze is removed there is elevation of pulse and temperature with constitutional and pelvic disturbances, then drainage and elimination are indicated.

The following officers were elected for the ensuing year: President, Howard J. Williams of Macon; first vice-president, J. G. Hopkins of Thomasville; second vice-president, I. H. Goss of Athens.

Place of meeting, Macon, the third Tuesday in April, 1899.

PRACTICAL NOTES.

Analgesic Application for Burns.—Vergely of Bordeaux, in burns of the first and second degree, covers the parts with a thick layer of paste of calcined magnesia and water, letting it dry on, replacing, as any becomes detached, by fresh paste. Pain ceases immediately, and the wounds heal without leaving any traces. Another treatment consists in the use of potassium nitrate as a refrigerant, in the form of baths or lotions. If a burn on the hand or foot is placed in a basin of water to which a few teaspoonfuls of potassium nitrate are added, the pain ceases. After a while, as the water heats up, the pain returns; then add more potassium. Continued for two or three hours, it frequently dispels the pain, and often prevents blisters. Compresses steeped in a saturated solution has the same effect.—*Am. Therapist.*

Lactophosphate of Lime for Acne and Furunculosis.—Purdon has been most successful with the treatment of acne and furunculosis with the syrup of the lactophosphate of lime. He regards it as "an agent of nutrition, and thinks it is appropriately given

in the conditions above referred to, as they are evidences of depraved nutrition." Be that as it may, the administration of this drug, coupled with the advice to the patient to wear Balbriggan linen undershirts, will prevent outbreaks of acne which occur from time to time on the shoulders and chest. If it is thought best to add cod-liver oil, the following prescription will be found palatable: *Acaciae, aquae, syr. calcis lactophosphat., ol. morrhuae, ol. amygd. amar.* Rub the gum, water and syrup together until a smooth mucilage is made, then gradually add the cod-liver oil with constant stirring, and lastly, the essential oil of bitter almonds. Thus made each tablespoonful of cod-liver oil and syrup of the lactophosphate of lime contains 4 grains of lactophosphate of lime and 50 per cent. of cod-liver oil.—*Dublin Journal of Medicine*, February.

Epithelioma of the Face Treated with Arsenious Acid.—Dr. Hermet, before the Paris Dermatological Society, reported a successful case of the above nature. The patient went to him in October, 1897, for the treatment of an epithelioma of the face. Arsenious acid was applied, the surface of the ulcer being left exposed to the air after the method of Czerny. The new growth was destroyed by the early days of January, 1898, and cicatrization was completed by February. The patient had previously been treated by chlorate of potassium without the slightest benefit. Czerny's method employed by Dr. Hermet consists in using three solutions of arsenious acid in equal parts of water and ethylic alcohol. The first solution, of the strength of 1 in 150, is applied to the ulcerated surface. The second and third, which are stronger, are applied to the scab. The ulcer is swabbed with the solution every day and excessive pain is kept in abeyance by a hypodermic injection of morphia. When the scab falls off the raw surface is treated as an ordinary wound. The case was reported to the society in March.—*London Lancet*, March 26.

Differentiation of Brain Tumors.—(From L. Bruns' address at Moscow Congress, *Wien. klin. Woch.*, 1897, 45, 46.) Although many of the symptoms of frontal and cerebellar ataxia are identical, he considers that monoplegia, Jacksonian convulsions, tonic deviation of the head and eyes to one side, and especially motor aphasia, denote frontal ataxia. On the other hand, paraplegia and alternating hemiplegias, visual paralysis on the side toward the tumor with crossed hemiplegia, double paralysis of the optic muscles and paralysis of the facialis and acusticus, distinguish cerebellar ataxia. He does not lay much stress on homonymous hemianopsia unless it exists on the right side from the first, combined with alexia and optic aphasia, when it indicates a tumor in the medulla of the left occipital lobe. He concludes by recommending percussion as extremely valuable. When the sensitiveness, tympanism and cracked pot noise are pronounced and extensive, they indicate plainly the general diagnosis of tumor, and when distinctly localized they point to its seat with precision, especially when the indications of the percussion sounds coincide with the symptoms observed. In the difficult differentiation of tumors in the central convolutions and neighborhood, distinctly circumscribed percussion sounds will often help more than even the cerebral symptoms, as they are scarcely possible unless the tumor is located at least near the cortex.

Kadner's Method of Investigating the Function of the Stomach, is described in the *Deu. med. Woch.* of March 31. It consists essentially in the test breakfast followed, just before the contents of the stomach are withdrawn, with the ingestion of 100 of a solution of sodium phosphate. The mixing of the solution with the test meal is facilitated with a few movements of the trunk, and the contents of the stomach are then withdrawn with ease. He has frequently used this method with great success in his practice, especially with ladies, and recommends it as simple and reliable. The phosphoric acid in the aspirated contents is then precipitated with an uran. solution, so con-

centrated that 25 c.c. precipitates all the acid out of 25 c.c. of the phosphate solution. The latter is saturated with acid and the amount of free acid in the aspirated contents is indicated with a one-tenth sodium (Lauge) solution and methyl orange. His formula for the phosphate solution is, $10 \text{ Na}_2\text{HPO}_4 + 12 \text{ H}_2\text{O}$ in 500 water with 28.10 c.c. normal salt solution; the mixture filled up to 1000. The formulæ for the tests are, $m = 100 (u - u') \div u'$, in which m = the amount of stomach contents being examined; $u = 25$ (amount of the uran. solution corresponding to 25 of the phosphate solution); u' = number of c.c. of the uran. solution required for 25 of the aspirated contents; $s = n (100 - m) \div m$, in which n = the number of c.c. of the one-tenth sodium solution required for 10 of the mixture to turn the methyl orange brown; s = the number of c.c. of hydrochloric acid in 10 c.c. of the original contents of the stomach.

Progress in the Immunization Treatment for Diphtheria at Berlin Hospitals.—When a case of diphtheria occurred in the surgical wards of the Kaiser and Kaiserin Friedrich Spital, of which Professor Baginsky is the Director, he immediately had all the other children immunized. In private families, when a case of diphtheria occurs, he does not consider immunization so necessary. Prompt segregation often prevents the disease from spreading to other members of the household, and as the doctor in such cases is in daily attendance, the serum treatment may be begun as soon as the first suspicious symptom is noticed in another child. Antitoxin, when given thus early in the disease, he considers an unfailing remedy. In patients injected during the first forty-eight hours of the disease there is absolutely no mortality. As Professor Heubner has for some time made it a practice to immunize all the children in his wards at the Charité every three weeks, it may be seen what a prominent place immunization has taken here during this last year. For a while Professor Heubner had to give up his immunizing injections because the hospital directorate thought it savored too much of experimental investigation on the children, and might arouse popular indignation. They were resumed after an interval of only two months, however, as it had become clear that they were wonderfully efficient in preventing diphtheria in the wards of the hospital. Absolutely no inconveniences have resulted from the practice.—*Medical News*.

Success of Local Frigor Therapeutics in Tuberculosis.—The refrigerating well at Geneva with its unparalleled low temperatures, -110°C. , about -100°F. , into which patients are lowered (*vide JOURNAL*, xxvii, 548) is chiefly remarkable on account of the ravenous appetite that follows the seances. This effect is particularly desirable in tuberculosis, but the treatment is too heroic for this disease. Letulle and Ribard now announce that by modifying the method and applying the refrigerating process locally for twenty to forty minutes they have succeeded in every case in restoring the appetite to such a degree that the patient starts upon a new existence, both physically and morally. They apply once or twice a day on the epigastric and hepatic region, a bag containing about two kilograms of solid carbonic acid, which has a temperature of minus 80 degrees C., and evaporates without moisture or residue. The skin is protected with a layer of cotton, and the peculiar effect is observed that it does not grow cold, but retains a temperature of plus 25 C., showing that it is diathermanous, while the organs within evidently feel the effect of the cold much more, and the organism rallies to protect them. It first utilizes the available stores on hand, as is shown by the fact that well nourished persons do not experience the same degree of hunger at first as those more emaciated. Their report in the *Bull. de la Soc. Méd. des Hôp.* for March 24, concludes: "This new cryomotherapy, simple, harmless and effective, can not be too warmly recommended, as it is evidently the physician's first duty to ensure sufficient alimentation to his tuberculous patients."

Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance	\$5.00
Foreign Postage	1.75
Single Copies	10 Cents.

In requesting change of address, give *old* as well as new location.
Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, 100 Washington St., Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the *Editor*, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

SATURDAY, MAY 7, 1898.

THE OBJECTIONS TO INTRAPERITONEAL DRAINAGE.

In a critical review of 1700 cases of abdominal section from the standpoint of intraperitoneal drainage, published by Dr. J. G. CLARK,¹ resident gynecologist of the Johns Hopkins Hospital, the objections to intraperitoneal drainage have been brought forward in a very clear and convincing manner.

Having considered quite extensively the physiology and anatomy of the peritoneum, with a view to bringing out its capacity for the absorption of fluids and solid particles from the peritoneal cavity and for disposing of irritant and infectious material, the following objections to drainage after abdominal section are considered.

Trauma and chemical irritation produced by the drainage material.—The effect of a foreign body upon the peritoneum is to cause endothelial destruction and inflammatory reaction. Anyone who is in the habit of making postmortem examinations will have observed that there is usually a much more intense inflammatory reaction around iodoformized and other forms of drainage than elsewhere in fatal cases of post-operative peritonitis. The action of the foreign body employed for drainage is very often aggravated by the action of the chemical substance, as for instance iodoform, with which the material is impregnated. Any mechanical or chemical irritation of the peritoneum must certainly be looked upon as tending to reduce its resisting powers against infection.

Retardation of healing.—In the drainage chart which Dr. CLARK has constructed from the 1700 cases it is very clearly shown that drainage retards local

healing. It can also be observed that the percentage of local suppuration conforms strictly to the rise and fall of the drainage line. These facts may be explained by mechanical injury, but the fact that the discharge from the drainage tract most often contains the bacteria normally found in the skin seems direct proof that they are introduced with the drain or gain entrance afterward. After the removal of the drain healing by granulation tissue, which is necessarily slow, is the only kind of healing that can take place. Hence the drain cases invariably remain much longer in the hospital than the undrained ones.

Drainage not effective in removing fluids and infectious material.—Postmortems show that all forms of drainage are quite frequently without success in removing fluids from the different parts of the abdominal cavity. The artificial efforts to remove fluids by means of the syringe, by means of mopping with pledgets of cotton, or by means of capillary absorption by a gauze drain, are not to be compared with the ability of the peritoneum for absorption. The presence of drainage material handicaps the peritoneum in various ways: the normal currents in the peritoneum are disturbed; the circulation of fluids and foreign bodies toward the diaphragm is interfered with; a reactive inflammation is set up by the drain which limits the action of the peritoneum, and within a few hours the general peritoneum is debarred from participating in the work of absorption, the work being thrown upon the drain, which can only remove fluid from a small pocket. A limited quantity of fluid is removed by the drain during the first few hours, but after that the drain rather acts like a plug by preventing the outflow of fluid, which then accumulates in the independent pockets. In some cases of drainage the drained fluid in CLARK'S cases showed myriads of microbes, while the portion of the general peritoneal cavity walled off by adhesions showed no traces of bacteria. Now, the advocates of drainage cite such cases in favor of the drain, as proving that it limits infection to the drained field, but Dr. CLARK thinks that the better explanation is, that the healthy peritoneum has successfully removed the infection while the drain has failed in its task of removing microbes from the pocket.

It is a general experience that there is a limit beyond which the peritoneum can not resist infection, and abdominal operations during active infection, especially of puerperal type, often terminate fatally, whether drained or undrained.

Infection frequently occurs from the drainage tract.—The bacteriologic investigations made in Dr. KELLY'S wards show that a gauze drain almost invariably becomes contaminated sooner or later, the variety and virulence of the micro-organisms depending upon the cleanliness of the surrounding skin, and to some extent upon the purity of the air. In every instance

of the sixteen tabulated cases in which the intraperitoneal gauze drain was examined bacteriologically organisms were obtained from some part of the drain.

In one hundred undrained cases referred to by Dr. CLARK where there were more or less adhesions, the operation being made for such conditions as tumors, cysts and extra-uterine pregnancy, only one case was complicated by the formation of post-operative pelvic abscess. In one hundred similar cases which were drained eight such undesirable sequelæ occurred. This fact goes far toward proving that the coagula and exuded fluid following these operations seldom suppurate if left to the care of the peritoneum, even though this may be more or less disabled.

Drainage in cases where infectious matter is supposed to be present at the time of the operation, is also shown by statistic studies to be unsatisfactory. In the first place a general review of the bacteriologic conditions in such cases, as pyosalpinx, abscess of ovary, peri-oophoritis, etc., seem to show that infection of the peritoneum from the diseased area at the time of the operation is not likely to occur, because the initial infecting organism has then generally disappeared or lost its virulence.

In the summary of the results in two series, each of one hundred cases of pelvic inflammatory disease, drained and undrained, it is shown that there were eighty uncomplicated recoveries in the one hundred undrained cases and only forty-six in the drained. It may be said that this comparison is not admissible, because the drained cases were probably the more serious. When, however, Dr. CLARK reviews the general abdominal operations in groups of hundreds, with the following drainage percentage: First hundred 74 per cent; second hundred 57 per cent; third hundred 48 per cent; fourth hundred 7 per cent; fifth hundred 10 per cent; and when many undrained cases in the last hundred are identical with some of those drained in the first and second hundreds then the essential difference between the drained and undrained cases would seem to be very slight.

Among the evil consequences of drainage are mentioned post-operative obstruction of the bowel, on account of the matting together of the intestines around the drainage tract, like a tangled skein of yarn; fecal fistula following drainage: in the only one in which this occurred in the Baltimore cases the fistula resulted from pressure necrosis produced by the glass tube; vesical complications, such as inflammatory reaction around the drain involving the fundus of the bladder and causing vesical irritation and dysuria; post-operative hernia: from certain statistics gathered by Dr. RUSSEL, one of the Gynecologic Clinic of the Johns Hopkins Hospital it appears, that at least 8 per cent. of the cases in which extensive drainage has been established have been followed by post-operative hernia.

Dr. CLARK then urges the following measures in order to avoid the supposed necessity for drainage in abdominal operations. These measures are aimed at preventing and removing infection without the drain. 1. Thorough disinfection of the hands. In view of the recognized difficulty, if not impossibility, of thoroughly cleansing the hands, ZWEIFEL's recommendation of suspending all operations for at least three days after contact with an infectious case, is urged as of value. 2. Control hemorrhage. 3. Avoid bruising or otherwise injuring the tissues. 4. Isolate the general peritoneal cavity during the operation. 5. Preserve the peritoneum. 6. Conserve the bodily heat, because it is generally accepted that resistance to infection is greatly decreased by lowering the temperature of the intestines. 7. Avoid rupture of intraperitoneal abscesses. 8. Irrigate the peritoneal cavity, which should be done after every operation, with normal salt solution, with a view of washing out all foreign matter that is possible. 9. Promote absorption by infusion of normal saline solution into the peritoneal cavity, followed by postural drainage. For this purpose from one-half to one liter of salt solution is introduced into the peritoneal cavity, especially when the operation has been prolonged or the presence of septic matter is suspected and the foot of the patient's bed is elevated 18 inches for the first twenty-four hours after the operation.

There can be no question concerning the first seven of these procedures. The last two may perhaps be open to discussion, especially because many surgeons insist upon dry technic in abdominal operations.

The postural method of draining the peritoneal cavity is recommended: 1. Because stagnating fluids are prevented from collecting in the dead spaces in the pelvis. 2. Infectious organisms are then quickly carried into the normal parts of the body, where they are destroyed before they can increase in number. 3. Toxic substances elaborated by the organisms are diluted and prevented from further injuring the wounded area. Dr. CLARK then presents certain facts that show the value of submammary saline infusions as a therapeutic agent in septicemia, and, finally, after this critical review of all classes of drain cases, the conditions in which drainage may be indicated are reduced to the following:

1. In appendicitis when the peritoneum and tissues adjacent to the appendix are infiltrated with inflammatory products, and when the appendix has ruptured and either cause localized abscess or general peritonitis. A definite objection to drainage in the area of the appendix is the liability of post-operative hernia in this district.

2. Localized collections of pus in the pelvis. Here the abscess sac should be enucleated and the abdomen should be closed without drainage, or it should not be opened from the abdomen if it is possible to enu-

cleate it safely. These cases are the ones especially suitable for vaginal incision.

3. Suture of the intestines. Here a drain should be employed only when there is doubt as to the integrity of the sutures.

4. Excision of fistulous tracts, leading from the intestine to the abdominal wall. In these cases it is safe to pack gauze down to the sutured areas of the intestine, because they are especially prone to break down and re-establish the fistula.

5. Purulent peritonitis. In purulent cases PAWLOWSKY has shown that the general avenues for absorption of fluids in the abdominal cavity are closed, consequently the surgeon must endeavor to supplement them by thorough irrigation of the abdominal cavity and free drainage.

THE ETIOLOGY OF CANCER.

The cause of cancerous disease is one of the questions that has been most actively discussed for a number of years past, and that still remains without a perfectly satisfactory solution. The general medical opinion is possibly inclined to be uncertain between a provisional theory that it is a reversional tissue degeneration and one that is of parasitic or infectious origin. The latter has had the strongest advocacy of late years in one form or another and suspicion that it may be correct, is at present, it may be, predominant.

The latest contribution to the subject is that of Dr. ROSWELL PARK in the May issue of the *American Journal of Medical Sciences*, and like other articles from his pen, it is interesting and suggestive. According to him, in order to attack successfully this problem of the origin of cancer, "pathologists of the future must begin by studying tumor formation in the vegetable world before studying it in animals, i.e., the comparative method of investigation must be adopted." He calls attention to the xylomata or woody tumors, some of which he does not hesitate to call by the name of vegetable cancers, and suggests the possibility of their being directly contagious to the human species, insects acting, it may be, as the carriers of the contagion. In support of this idea he adduces certain facts of the distribution of cancer, and the researches of NOEL, who found a relation between it and vegetable growths. Foresters and excise officials who have to spend much time in shady wood paths, it would seem are especially liable to cancer, as are also those who dwell in wooded districts or shaded dwellings. This fact has not been generally recognized in the etiology of cancer, but it seems worthy of consideration and further investigation as to its universal applicability. It would be, it would seem, worth while to collect more statistics on this point and find whether malignant tumors are increasing as our prairie States become more timbered or decrease with the clearing of the forests in those regions where deforestation is

still in progress. In New York, according to the figures of the State Board of Health, quoted by Dr. PARK there has been a steady increase of deaths reported from cancer; 1882 deaths in 1885; 2878 in 1890, and 3454 in 1895, or nearly twice as many as ten years before. It is not probable that the timber distribution alone could account for this difference, and so far as they go these figures give no special support to the theory suggested, but rather indicate that there must be other and still more effective causes at work that are still undiscovered. The possibility of an increasingly malignant contagion is strongly suggested by such statistics and accords with the parasitic theories of the disorder that are coming into vogue.

Dr. PARK gives an interesting review of the studies and theories of the etiology of cancer and divides them into three periods: 1, that of inaccurate observations and erroneous conclusions, beginning with NEPVEAU in 1872; 2, that of accurate observation but of mistaken deduction (the coccidial period); 3, that of iconoclastic doubt, from RUSSELL (1890) to BANTI and NISSER (1894); and 4, that of successful inoculation by the Italian observers RONCALI and SANFELICE within very recent years. From the results obtained by these last it would appear that the infectious nature of cancer has been fairly established, at least within certain limits, and that certain fungi, the blastomycetes, are probably the most active agents of the infection. This accords with the theory of the vegetable origin of the disease, a low vegetable organism and one of a class that has not hitherto been so commonly regarded as containing pathogenic species, being apparently the source of the infection. It is entirely possible, nevertheless, that in the future we may yet find other germs capable of exciting the morbid process under certain conditions, and among them some of those forms that have been from time to time offered as the causative factors. The failure of inoculation experiments is not an absolutely conclusive fact against their active agency, and the cancerous process in cell growths may easily be one that can be set up by more than one kind of irritation.

If cancer is increasing elsewhere at the rate it appears to be in New York State, the question of its etiology and its prevention will before long be well to the fore amongst the sanitary problems that interest our profession.

THE ARMY AND NAVY MEDICAL DEPARTMENTS.

Great interest is naturally felt by the medical profession in the composition and organization of the Medical Departments of the Army and Navy on their war footing, and particularly of that part which will constitute the column of attack upon the Spanish forces in Cuba. The call for volunteers to sustain the National flag has stirred the pulses of many medical men, young and middle-aged, who are earnestly inquir-

ing how their professional services may be utilized. Their questions can be answered readily, for the ranks of the Medical Corps of the Army may be said to be already filled. A board is now in session in Washington, D. C., examining candidates for position in the regular medical service, but this is not a war measure. It is the routine process by which the vacancies occasioned by death and retirement are filled annually, and it would have been in session now irrespective of any declaration of war by this country. The regular regiments have been gathered up from the garrisons of the interior and concentrated at certain points in the South. Each regiment brought with it to the rendezvous its quota of medical officers and members of the hospital corps, and it lies now with the chief surgeon of each division thus aggregated to organize its medical department, under instructions from the Surgeon-General, in the manner most suitable for the service that seems in immediate prospect. There is yet, fortunately, on the active list of the Corps a number of officers who are competent to supervise this work by virtue of having served their apprenticeship with large bodies of troops during the Civil War. In like manner each regiment of State volunteers will bring with it to the rendezvous its surgeon, two assistants and its hospital corps men to be mustered into the United States' service and to be drilled, disciplined and organized under the instructions of the Surgeon-General and the supervision of veteran officers. As these volunteers come mainly from the National Guard it is safe to say that the medical officers of the Guard will not give State governors the opportunity of filling many vacancies by the appointment of men who have not heretofore manifested their military proclivities in a practical way by membership in the Guard. There is therefore no likelihood of an immediate opening for the many who are anxious to serve their country under the Red Cross flag of the Army Medical Department.

Nor does the Navy offer any greater facilities for service. Several cruisers have been extemporized out of ocean liners and these require a medical staff; but the Department, in consideration of a few acting assistant surgeons recently appointed under the authorization of Congress, would be able to fill all the necessary positions if its own ranks were recruited up to the maximum allowed by law. We understand that the only volunteers acceptable to the Navy Medical Department are volunteers to compete for the seventeen vacancies now existing in the Corps. The limit of age for candidates has recently been extended from 26 to 30 years, thus allowing many to compete who have hitherto been ineligible.

Surgeon-General VAN REYPEN's ambulance ship, the *Solace*, was expected to be ready for sea service by May 3. This vessel is a new departure in naval warfare. We had hospital ships in the War of the

Rebellion, but they were merely transports. This is intended to be to the battleships, during an engagement, what the field division hospital is to the line of battle of the Army. She is outfitted with steam launches to convey the wounded from their stations to the comparative quiet and security guaranteed by the flag of the Geneva Convention. The *Solace* has beds for two hundred patients, and in an emergency hammocks can be slung for one hundred additional cases. The after part of the hurricane deck has been set aside as an isolation ward for cases of infectious disease. Change in the construction of war ships necessitating change in the methods of caring for the wounded has been met promptly by the Navy Medical Department.

THE PRESIDENT'S CALL FOR VOLUNTEERS.

The call of the President for 125,000 volunteers gave occasion to military writers to discuss the status of the National Guard, volunteering individually or by organizations and the appointment of officers. Were medical writers to discuss the call they would probably animadvert on the physique of the volunteer and the need for careful medical inspection to ensure that only the right men obtained position in the ranks. This appears to have been provided for by the authorities, for although local medical officers have no doubt passed on the physique of all members of the National Guard, army medical officers have been sent to the rendezvous to inspect the men prior to their muster into the United States service. As the number called out is small compared with the population of the country, only well-grown and perfectly sound men should be accepted. The minimum age for enlistment in the army is twenty-one years. This is as it should be; but the acceptance of volunteers from eighteen to twenty-one will crowd the ranks with immature constitutions which will break down under the strain of war service, giving a large sick list, a heavy death rate and a long pension roll for consideration hereafter. Britain accepts youths of this age, but she keeps them at the home stations, as at a training school, until they have attained their maturity.

The danger from yellow fever is another subject which runs in the minds of medical men in this connection. The newspapers have discussed it so freely that every volunteer in considering his risks thinks less of Spanish bullets than of this dangerous pestilence. Disease is usually more fatal to armies than battlefield casualties. For every man who was killed or died of wounds during the civil war two men died of disease, although yellow fever contributed but little to the total. It was expected that our armies would be more than decimated by this fever, but they were not. New Orleans was kept free from fever, although garrisoned by unacclimated men from the

North. Troops at New Berne, Hilton Head, Key West, Wilmington and several other points became infected, but military discipline and military sanitation prevented any spread of the disease. It is well to enlist regiments of immunes for service in Cuba, and particularly to garrison any infected town, but we are of opinion that the danger to our troops has been unnecessarily "exploited" and exaggerated. It should be remembered that the discipline and sanitary administration of a military camp afford the very means for preventing the occurrence of the disease or stamping out its infection if it should be introduced. When the city of Memphis, Tenn., suffered so severely in 1879, those of the inhabitants who moved into camp at a distance of a few miles were preserved, although the government of the camp was not as strict as it should have been. The surgeon-general of the army has made yellow fever the special study of his life, and it is certain that every precaution will be taken to prevent disability and death from its infection.

THE JOURNAL SPECIAL TRAIN TO DENVER.

The Journal Special Train will leave Chicago, Saturday, June 4, at 11 P.M., via the Chicago, Burlington & Quincy Railroad, arriving in Denver Monday morning 7 A.M., in time for the meeting of the American Academy of Medicine, the American Medical Editors' Association and other medical organizations holding sessions on Monday.

The "Special" will run through. Tickets will be good for thirty days. The rate will be one fare and \$2 for the round trip, the most favorable rate yet granted the ASSOCIATION.

PROGRAM OF SECTIONS.

The Secretaries of Sections will, if they have not already done so, please forward program of their Section immediately to the JOURNAL office. This year we desire to get out the program on time, and it will not be the fault of the JOURNAL office if it is not ready.

CORRESPONDENCE.

The Yellow Fever Amebæ.

CHICAGO, May 1, 1898.

To the Editor:—General Sternberg is in error if he suggests that I have not taken the trouble to read his report on yellow fever which he gave me personally after having discussed the question with him (1895). I have not only studied his very valuable but not fruitful researches, but have expressed also the highest respect for his investigation in my papers.

The report of Dr. Councilman, as I now see, is the most valuable work done to this time on the pathology of yellow fever. I had not at this time, to my regret, given it enough weight; but I may be excused, as he himself rejected the idea of parasites and declared his finding as a curious form of necrosis, sometimes affecting only portions of the liver cells. As Councilman found the same masses in rapidly advancing cases of cirrhosis of the liver, in phosphorus poisoning and in other cases of rapid fatty degeneration, particularly in cases of yellow

atrophy of the liver, the observation was not retained in my mind as possibly of a higher value than the author himself laid upon it. Indeed, I did not remember it at the time. I commenced my own researches at the commencement of this year and found in the liver the same startling alterations described so well, but misinterpreted, I think, by Councilman. Permit me to explain in brief.

1. I have never seen such forms of partial necrosis of liver cells in any of the cited liver diseases; the amyloid and colloid affections of the liver are quite different; possibly only some forms of acute red atrophy of the liver may contain similar bodies, described by me long ago as yellow atrophied liver cells (Klebs, "General Pathology," T. 2., p. 364, Table 21 and Fig. 32). Looking at this picture, I can not refrain from the suggestion, that amebæ were also present here. Of these oval and egg-shaped bodies, some contained a nucleus, some did not. The preparation was stained with carmin-alum. These bodies are found in the interstitial tissue and between the liver cells, the protoplasm of the latter showing a fine network, very similar to the yellow liver cells. I remarked (l. c., p. 368): "Whether in this case other forms of parasites, for instance, 'gregarinae,' are present for which the yellow bodies could be taken. I do not venture to decide."

2. As to my opinion upon these bodies in the yellow fever liver, I may be permitted to repeat the following remark from my paper: "The sharply defined form of these bodies, their different staining, their disposition in the interstitial tissue and in the liver cells, their forming of vacuoles and pigment in the more advanced stages, certainly indicate them to be parasites of the class of protozoa; but having only dead material before me, I will not decide the question, unless they could be found in other organs in physiologic connection with the liver."

With what is clearly expressed, that only a detection of the same bodies in the parts connected with the liver or stomach and duodenum would give a higher degree of probability to my suggestion, Dr. Sternberg himself pointed out to me the affection of these organs as a constant feature of yellow fever. So I was very much gratified to find in the inflammatory areas of these organs quite the same bodies and also sporulating forms. It is not justifiable, therefore, to declare my opinion not tenable, as it is based on much more extensive observations than Councilman's.

3. I will repeat here from my paper, that this new theory of yellow fever as a protozoic affection "must be supported by the examination of yellow fever patients." EDWIN KLEBS.

Foreign Bodies Removed from Abdomen.

VIROQUA, WIS., April 19, 1898.

Dr. M. R. GAGE, Phoenix, Ariz., Dear Doctor:—Aware of the interest you have hitherto taken in the case of Miss Clara Condit (the late Capt. Condit's daughter), now an inmate of our County Asylum, I have thought best to put you in possession of some facts of late development regarding the unfortunate woman which, I think, will prove of interest to you. Saturday morning last I was requested by Dr. Morley of this place, physician in charge at the asylum, to see with him the patient referred to. The nurse in charge informed us that early that morning the patient called her attention to a small swelling in her right upper groin which was painful and interfered with her movements more or less, and also reiterated the statement made a month or six weeks before that she had swallowed two teaspoons, a table knife, and the glass tube of an ordinary thermometer broken into fragments for convenience in swallowing. Her statement first made seemed to the nurse, superintendent and wife to be so improbable that but little attention was given to it especially in view of the fact of the absence of gastric and intestinal symptoms from first to last, with the exception of an occasional attack of diarrhea

with "black looking stools," to use the nurse's expression; her appetite was good, pulse and temperature normal, and she had the freedom of the ward at will.

Our examination disclosed at the upper margin of the right groin an oblong swelling, hard, tender to the touch, of a dusky red color, of small dimensions, and nonfluctuating; from right to left obliquely upward a hard, resisting, oblong shaped mass could be distinctly outlined without subjecting the patient to any pain to speak of. In answer to my question whether she had swallowed what she told the nurse four or six weeks ago she had, her reply was affirmatively.

We rather concluded that a foreign body of some kind was located in the region alluded to, and in order to determine its nature, metallic or otherwise, thought best to make a needle exploration; this proved the lodgement of a metallic body of some kind, probably a spoon large or small. The pulse and temperature taken at this time was normal, and abdominal palpation revealed nothing of consequence. The following day the patient was chloroformed, an incision of the tumor made by Dr. Morley and a table knife ten inches long, five-eighths wide, presenting blade end first was drawn through the wounds without difficulty; it was blackened, with a somewhat serrated edge and had adhering to it a number of raisin seeds. No fecal matter or odor escaped from the cavity in which the implement was lodged showing, it seems to me, no communication with the lumen of the cecum. The operation, happily, was extra-peritoneal. I, therefore, see no reason why the patient should not recover from its effects, and, moreover, had not the conditions of things been discovered at the time already stated, nature would have anticipated the knife by an opening within a few days through which the foreign body could have been readily extracted. It is rather surprising that such a foreign body received into the stomach by accident or design, could traverse almost the entire length of the intestinal canal, pass through the ileo-cecal valve into the cecum, there lodge for a time, finally to penetrate its coats into the ileo-cecal fossa and become imbedded in exudate tissue from time to time shutting it off from the abdominal cavity, without causing a train of symptoms indicative of mischief. In this case, however, there were as stated absolutely no symptoms attending the travels of the knife as far as it went in the intestinal canal.

Yours truly,

WILLIAM A. GOTT.

Section on Cutaneous Medicine and Surgery.

SAN FRANCISCO, CAL., April 23, 1898.

To the Editor:—In the issue of the JOURNAL of April 9, 1898, there is published the masterly address of Dr. A. Ravogli, the chairman of the Section of Cutaneous Medicine and Surgery, delivered at the forty-eighth annual Meeting of the Association, in which there appear one or two inaccuracies, which would work an injustice to the session of the Section at the Meeting of the year 1895, at Baltimore, Md., and of which I had the honor of being chairman, and furthermore might incidentally reflect unfavorably upon the Pacific coast unless corrected. I would have written to my friend, Dr. Ravogli, and I feel assured that, after his attention had been called to the matter, no one would have been more willing to rectify the errors which no doubt crept unwittingly and unnoticed into his address, than the Doctor himself, but as you as editor corroborated his statements, with which issue is taken here, I feel it incumbent upon me to kindly ask of you the insertion of this communication in the next number of the JOURNAL, so that justice may be done all around. The inaccurate statements complained of occur in Dr. Ravogli's address on page 814 in the following phrases, to-wit: "At the meeting in San Francisco in 1894, Dr. Ohmann-Dumesnil of St. Louis, was chairman, and Dr. L. F. Frank of Milwaukee, was secretary. In 1895 Dr. E. [meaning A. E.] Regensburger of San Francisco, was chairman, and Dr.

D. H. Rand of Portland, Ore., was secretary. No report of the work of this Section can be found in the JOURNAL for these years and not even the programs appear in the records."

The foregoing assertions of the Doctor are strengthened by your foot note to the effect that "None of the papers were received by the JOURNAL.—Ed." These statements, if allowed to go unchallenged might lead anyone unfamiliar with the facts of the case to believe that this coast took no interest in dermatology, or at all events in the Dermatological Section of the Association. This is very far from being so. While I admit that the session of 1894 at San Francisco was not as interesting as it might have been, yet there was a good attendance and when we consider that both the chairman and secretary were absent from the session, we must concede that the Section did quite well under those circumstances. As regards the meeting of the Section in 1895 at Baltimore, I can safely affirm without fear of contradiction, that the number of papers presented and read, the character of the discussions, and the high scientific standard and practical value of the work accomplished will compare favorably with that of any other session of the Section. Dr. Duhring of Philadelphia and Dr. Bulkley of New York, who were present, were more than pleased. Dr. Bulkley said that some of the work, especially referring to a paper on psorospermiosis cutis by Dr. Gilchrist of Baltimore, was some of the best ever presented in the Section. Other excellent essays were contributed by Drs. Bulkley and Gottheil of New York, Ohmann-Dumesnil of St. Louis, Mathews of Louisville, Ky., and Mathews, as well as the chairman's address by your humble servant. Dr. Ravogli himself sent in a very creditable production on "Ulcerative Syphilide of the Pharynx," which with some other papers read there is printed on page 102 of the *Journal of Surgery*, 1896.

How Dr. Ravogli could have forgotten all these facts I am unable to say. Now that his attention has been called to them he unquestionably will admit their correctness. Most of these papers and many others read before the Section at that session were printed in the JOURNAL. A program of the work of that session, although not perfect, can be found in the JOURNAL of April 6, 1895, page 526, and still more complete ones in subsequent numbers of that publication.

Hoping that these explanations will set things aright and give credit where it is due, I remain, Yours fraternally,

ALFRED E. REGENSBURGER, M.D.

Parovarian Cysts.

MILWAUKEE, WIS., April 28, 1898.

To the Editor:—I notice, in the last issue of the JOURNAL, reference made in regard to Beyla's and Kelly's cases of enucleation of parovarian cysts without the removal of the tubes and ovaries, with the remark that those are the only cases ever reported.

I have reported one case in the Transactions of the Wisconsin State Medical Society, 1897.

The operation was done in July, 1895. Two parovarian cysts were removed: the right one was about the size of a small coconut. It was very easily enucleated. The top of the broad ligament was torn open with the finger and the cyst readily shelled out intact. The one in the left broad ligament was also enucleated, but with greater difficulty. Both were successfully removed without interfering with the tubes and ovaries. The patient made an uninterrupted recovery.

Yours respectfully,

F. SHIMONEK, M.D.

The "Inverted Pyramid of Accumulated Honors."

SHELBYVILLE, IND., April 30, 1898.

To the Editor:—I do not wish to be hypercritical, nor to be considered an *old foggy*, but I have often been painfully im-

pressed with the thought that perhaps too many of the valuable papers in the JOURNAL are over-burdened with the various titles and honors that have from time to time been conferred on the author.

When I read an article in a medical journal I like to know the name of the writer, especially if there is anything new or original in it, but I confess it makes me *tired* to see a long list of colleges and hospitals he may have performed brief service in, as well as the various societies into whose *not exclusive* halls he has been admitted, hanging like an excrescence to his ethical title of M.D., in the shape and size of a huge *Abracadabra*.

W. GASTON McFADDEN, M.D.

ASSOCIATION NEWS.

Section on Practice of Medicine.—All members of the AMERICAN MEDICAL ASSOCIATION expecting to attend the banquet of the Section on Practice of Medicine are requested to notify Dr. S. A. Fisk, Chairman, 37 Eighteenth St., Denver, Colo.

The Journal Train.—Arrangements have been perfected with the Burlington Route for the Journal Special to the annual meeting of the AMERICAN MEDICAL ASSOCIATION, to be held at Denver, Colo., June 7 to 10, 1898, leaving Union Passenger Station, Canal and Adams Streets, Chicago, and to be run on the fast schedule shown below:

Schedule of Burlington Route. Leave Chicago 11 P. M., June 4; Mendota 1:40 A. M., June 5; Galesburg 4:10 A. M., June 5; Burlington, Iowa, 5:40 A. M., June 5; Fairfield 7:25 A. M., June 5; Ottumwa 8:10 A. M., June 5; Chariton 9:50 A. M., June 5; Osceola 10:35 A. M., June 5; Pacific Junction 2:10 P. M., June 5; Lincoln, Neb., 4 P. M., June 5; arrive at Denver 7 A. M., June 6.

Equipment. The Journal Train will run solid from Chicago to Denver and will be composed of the Pullman Company's finest equipment. It will carry a Burlington Route dining car through to Denver, in which meals will be served *à la carte*, special attention being paid to this part of the service.

Rate. A rate of one fare plus \$2 from Chicago, St. Louis, Peoria, St. Paul, and all territory within the Western Passenger Association, has been secured. Net fare from Chicago and return, \$31.50. Tickets may be purchased June 2, 4 and 5 at your point of departure, and are valid for passage to final destination point in Colorado up to and including June 7.

Special forms of tickets will be used and purchaser may begin return trip on any date desired between June 12 and July 6. Railroad passage and Pullman tickets may be obtained at any Burlington Route ticket office. Chicago offices are located at 211 South Clark Street, corner of Adams, and at Union Depot Passenger Station, corner of Canal and Adams Streets.

The hour of departure, 11:00 P. M., is most convenient, as it will enable passengers on trains from the East to arrive in Chicago in ample time to make connections with the Journal Train. The schedule will also allow delegates throughout Iowa to meet the train at convenient hours, and will arrive at Denver at an hour which will enable the members of associations other than the AMERICAN MEDICAL, which hold their meetings previous to its meeting, ample time to attend them.

Sleeping car rates are \$6 for a double berth from Chicago to Denver. Two persons can occupy a double berth, if they desire, making the cost \$3 for each person.

The entertainment of members and their families is being planned on an elaborate scale, and the committee promises all who come a most enjoyable time and a meeting full of scientific interest and social entertainment unsurpassed. Denver is an interesting city and the State offers many and varied attractions to visitors. Local excursions are being arranged to take

place after the meeting, that all may have ample opportunity of visiting various points of interest in the State and seeing the best scenery of the Rocky Mountains.

A complimentary excursion has been arranged to Colorado Springs and Manitou, which will enable the delegates and friends to visit Pike's Peak, Ute Pass and "Garden of the Gods."

Information regarding the Journal Train will be promptly furnished in reply to application by letter or telegram addressed to City Passenger Agent Frank E. Bell, 211 South Clark Street, Chicago, who will also reserve sleeping car space and furnish tickets.

Trans-Mississippi Exposition. No doubt many of the members and their friends will wish to visit the Trans-Mississippi Exposition at Omaha on their return. In order to permit of this, arrangements have been made for a stop-over as long as desired, up to the time limit of the tickets purchased for the Journal Train. A cordial invitation is extended the members and their families, by a committee appointed by the leading physicians of Omaha, for the purpose of extending to them the hospitalities of the city, and also by the Medical Director of the Exposition, Dr. E. W. Lee, to make the hospital their headquarters while on the grounds, where every courtesy and convenience will be arranged for their comfort.

Section on Ophthalmology.—AMERICAN MEDICAL ASSOCIATION, annual meeting at Denver, Colo., June 7-10, 1898.

Chairman's Address.

The Percentage of Color Blindness to Normal Color Vision as Computed from 3019 Cases, by J. Aloysius Miller, Houston, Texas. Discussion opened by Frank Allport, Chicago, Ill.

Glioma of the Retina, by J. L. Thompson, Indianapolis, Ind. Discussion opened by J. F. Fulton, St. Paul, Minn.

A Case of Mathematically Perfect Eye, by Geo. M. Gould, Philadelphia, Pa. Discussion opened by Henry Gradle, Chicago, Ill.

SYMPOSIUM, USES OF ELECTRICITY IN OPHTHALMOLOGY.

a, Some Uses of Electricity in Ophthalmic Practice, by H. M. Starkey, Chicago, Ill. b, Galvanism in Choroiditis, by R. F. Le Mond, Denver, Colo. c, The Uses of Electricity in Ophthalmology, by S. Lewis Ziegler, Philadelphia, Pa. Discussion opened by C. H. Williams, Boston, Mass., and by W. H. Wilder, Chicago, Ill.

The Treatment of Corneal Ulcers with Pure Oxygen, by T. H. Woodruff, Chicago, Ill.

Phlyctenular Keratitis, by D. S. Reynolds, Louisville, Ky. An Easily Overlooked Form of Keratitis, by Henry Gradle, Chicago, Ill. Discussion opened by J. J. Kyle, Marion, Ind.

The Treatment of Blepharitis with Formalin, by Herbert Moulton, Ft. Smith, Ark.

The Frequency of Senile Opacity in the Crystalline Lens and the Proper Definition of Cataract, by Edward Jackson, Philadelphia, Pa. Discussion opened by E. C. Rivers, Denver, Colo.

Accidents in Eye Operations, by F. C. Heath, Indianapolis. Bacteria one of the Chief Etiological Factors in Diseases of the Eye, by Ellet, Orrin Sisson, Keokuk, Ia.

Conclusions from Some Clinical and Bacteriological Experiments with Holocain, by Robert L. Randolph, Baltimore, Md. Discussion opened by H. V. Würdemann, Milwaukee.

Five Cases of Congenital Bilateral Dislocation of the Crystalline Lens in Three Successive Generations, by Edward F. Parker, Charleston, S. C.

An Additional Case of Double Microphthalmus, by Cassius Wescott, Chicago, Ill. Discussion opened by G. E. de Schweinitz, Philadelphia, Pa.

The Use of Aluminium for an Artificial Vitreous, by D. C. Bryant, Omaha, Neb. Discussion opened by Herbert Claiborne, New York, and L. Webster Fox, Philadelphia, Pa.

Gonorrheal Iritis and Conjunctivitis, by Frank S. Milbury, Brooklyn, N. Y. Discussion opened by F. J. Sampson, Creston, Iowa.

Iritis Spongiosa, by Adeline E. Portman, Washington, D. C. Serous Cysts of the Iris, by Louis F. Love, Philadelphia, Pa. Discussion opened by Wm. L. Dayton, Lincoln, Neb.

Report of a Case of Hemorrhagic Retinitis (idiopathic?), by Vard H. Hulén, Galveston, Texas.

A New Perimeter, by C. H. Williams, Boston, Mass.

Report of a Case of Quinin Amaurosis, by J. M. Ball, St. Louis, Mo.

Some Severe Cases of Tobacco and Quinin Amblyopia, by E. C. Ellett, Memphis, Tenn.

Some Results in Cases of Tobacco Amblyopia, by L. J. Lautenbach, Philadelphia, Pa.

Amblyopia from Auto-Intoxication, by Henry B. Young, Burlington, Ia.

The Clinical Aspects of Toxic Amblyopia, by Casey A. Wood, Chicago, Ill.

The Pathology of Toxic Amblyopia, by G. E. de Schweinitz, Philadelphia, Pa. Discussion opened by F. C. Hotz, Chicago, Ill., and W. H. Wilder, Chicago, Ill.

SYMPOSIUM: THE TREATMENT OF AFFECTIONS OF THE LACHRYMAL APPARATUS.

The Conservative Treatment of Epiphora and Affections of the Lachrymal Apparatus, by Samuel D. Risley, Philadelphia.

Treatment of Disorders of the Lachrymal Apparatus, by Leartus Conner, Detroit, Mich.

The Treatment of Suppurative Dacryocystitis, by Arthur Prince, Springfield, Ill.

The use of Large Probes in Strictures of the Lachrymal Duct, by G. M. Black, Denver, Colo.

The Value of Large Probes in the Treatment of Strictures of the Nasal Duct, by H. O. Reik, Baltimore, Md.

On the Use of Probes in Affections of the Lachrymal Apparatus, by F. M. Chisolm, Baltimore, Md.

Some Experience with Extirpation of the Lachrymal Sac, by J. E. Colburn, Chicago, Ill.

Extirpation of the Lachrymal Sac and Gland, by C. R. Holmes, Cincinnati, Ohio. Discussion opened by B. E. Fryer, Kansas City, Mo., and Chas. Robertson, Davenport, Ia.

Report of a Few Cases of Acute Glaucoma, by H. Bert Ellis, Los Angeles, Cal.

A Case of Hereditary Glaucoma, by H. Harlan, Baltimore.

Glaucoma and Detachment of the Retina, by Wm. Cheatham, Louisville, Ky. Discussion opened by J. L. Thompson, Indianapolis, Ind., and John Chase, Denver, Colo.

Regular Astigmatism is not Always Congenital, Neither is it Unchangeable, by Wm. C. Bane, Denver, Colo. Discussion opened by S. B. Risley, Philadelphia, Pa.

The Field of Fixation or Home of the Guiding Sensation, by G. C. Savage, Nashville, Tenn. Discussion opened by F. B. Eaton, San José, Cal.

The Dynamics of the Extrinsic Ocular Muscles as the Result Obtained by the Examination of 100 Medical Students, by Flavel B. Tiffany, Kansas City, Mo.

Eye Muscle Tests with Colored Glasses, by F. B. Eaton, San José, Cal.

A New Element in the Etiology of Strabismus, by Geo. T. Stevens, New York, N. Y.

Unsatisfied Sexual Desire a Cause of Heterophoria in Both Sexes, by L. R. Culbertson, Zanesville, Ohio. Discussion opened by J. M. Bannister, Ft. Leavenworth, Ark., and D. W. Stevenson, Chicago, Ill.

Epithelial Lip Grafts for Large Wounds of the Conjunctiva, by F. C. Hotz, Chicago, Ill.

Recent Experience with Advancement of the Recti Muscles, by C. H. Beard, Chicago, Ill.

Additional Notes on the Employment of Absorbable Sutures in the Operation of Looping the Tendons of Ocular Muscles, by J. O. McReynolds, Dallas, Texas. Discussion opened by O. Dodd, Chicago, Ill.

Variability of the Visual Field in the Case of Disease of the Heart, by W. F. Southard, San Francisco, Cal.

Preparation of Macroscopic Eye Specimens, H. V. Würdemann, Milwaukee, Wis.

Report of Some Cases of Hereditary Ectopia Lentis, by W. H. Wilder, Chicago, Ill.

Remarks on De Zeng's Refractometer, by Frank Allport, Chicago, Ill.

SOCIETY NEWS.

American Medical Temperance Association. The eighth annual meeting of the American Medical Temperance Association will be held at Denver, Colo., June 8, 1898. The meeting will be confined mostly to the annual business of the society, accepting the address by the President, Dr. N. S. Davis of Chicago. The members of this society are all members of the AMERICAN MEDICAL ASSOCIATION, and the various papers which naturally would be read before the society are now presented and read before the different Sections. This is thought to be more

practical, in attracting attention and discussion, and bringing out the facts before a wider audience. This association is composed of physicians who wish to study the alcoholic problem above all theory and prejudice, and who believe there is a medical and scientific side of this subject not well known, but of the greatest practical interest. This society has already a membership of two hundred physicians, and is modeled after the English society which has a membership of six hundred medical men. France, Germany and Switzerland have similar societies, and the membership comprises many of the leading medical teachers of the world. These societies have all the same end and purpose, viz: to ascertain the value of alcohol as a remedy, and its physiologic action in health and disease. It is believed that medical men can not only decide these questions but can point out solutions of the many vexed problems of alcohol as a beverage, and its effects on society and civilization, and also the practical measures to break up the evils which follow from it. The American Association, like the other societies of Europe, simply aim to ascertain the facts about alcohol, irrespective of all conclusions, and are confident that when the profession takes up this subject in this spirit the most practical results will follow. A "Bulletin" is published giving the new facts along these lines. All members of the AMERICAN MEDICAL ASSOCIATION who would like to help on this work are most cordially invited to join this society. The secretary will furnish all particulars and blanks for membership by addressing him. He will also be pleased to meet any one in Denver who may wish to join in the work.

Address,

T. D. CROTHERS, M.D.,

Secretary, Hartford, Conn.

American Neurological Association.—The Council announces that the twenty-fourth annual meeting of the Association will be held in New York at the New York Academy of Medicine, No. 17 West Forty-third Street, May 26, 27 and 28, 1898. There will be two sessions daily, one from 10 A.M. to 12:30 P.M., the other from 2 P.M. to 4:30 P.M. Send the title of your paper to the secretary, 1719 Walnut Street, Philadelphia, as soon as possible, so as to facilitate the publication of a preliminary program.

Cumberland County (N. J.) Medical Society.—This Society held its annual meeting at Millville April 12. The following officers were elected for the ensuing year: President, Dr. Judson, Newport; vice-president, J. B. Ware, Bridgeton; secretary, Hamilton Mailly, Bridgeton; treasurer, Joseph Tomlinson, Bridgeton; reporter, J. C. Applegate, Bridgeton. Delegates were elected as follows: AMERICAN MEDICAL ASSOCIATION, Drs. H. W. Elmer, T. G. Davis, W. L. Newell; State Medical Society, Drs. L. L. Hand, M. K. Elmer, J. B. Ware, Ellsmore Stites, D. H. Oliver, Rulon Dare; Gloucester County Society, Drs. D. H. Oliver, Ellsmore Stites and J. C. Applegate.

Kentucky State Medical Society.—The following papers are to be read at the Maysville meeting of the Society, May 11, 1898:

A Contribution to the Study of Eye Strain as a Cause of Nervous Diseases, by A. G. Blincoe, Bardstown.

Vaccination, by B. W. Smock, Louisville.

Treatment of Fistula in Ano, by John M. Williams, Louisville.

A Case of Bright's Disease in a Child Three Years of Age, by T. B. Greenly, Meadow Lawn.

Causes and Prevention of Glaucoma, by Richard Taylor, Louisville.

Utility of the Blood Clot in the Treatment of Wounds, by R. C. McChord, Lebanon.

Diagnosis and Treatment of Stricture of the Urethra, by W. R. Blue, Louisville.

Analysis of the Earliest Manifestations of Tuberculosis, by Frank C. Wilson, Louisville.

Uterine Displacements and Their Treatment, W. Esterly Ashton, Philadelphia, Pa.

Ether Pneumonia, by James M. Anders, Philadelphia, Pa.

Gummatous Deposits in the Iris, by Crittenden Joyes, Louisville.

Hazardous and Unwarranted Substitute Procedures in Ophthalmic Surgery, by W. B. Meany, Louisville.

Remarks on the Treatment of Cystitis, by J. G. Garrick, Lexington.

Membranous Croup and Intubation, with Report of Cases, by G. G. Thornton, Gravel Switch.

The Diagnosis and Treatment of Stone in the Common Duct, by H. J. Cowan, Danville.

Abortion and Its Treatment, by E. A. Cherry, Morgantown. The Rational Therapeutics of Some of the Animal Extracts, by R. Alexander Bate, Louisville.

Treatment of Typhoid Fever, by James F. Rinehart, Springfield.

Ether Anesthesia, by Robert Carothers, Newport.

Mental Responsibility, by Dudley S. Reynolds, Louisville.

Surgical Treatment of Hemorrhoids, by P. H. Stewart, Paducah.

The Physiology of the Liver and the Role it Plays in Digestion and Nutrition, by George E. Davis, Lawrenceburg.

Preventive Medicine and Allied Sciences, by Lyman Beecher Todd, Lexington.

Kidney Failure, by Ewing Marshall, Louisville.

Diagnostic Value of the X-Rays, by J. T. Dunn, Louisville.

Deflection of the Nasal Septum, by Thomas C. Evans, Louisville.

Typhoid Fever; Etiology and Treatment, by J. P. Heavrin, Owensboro.

Constipation, by G. J. Monroe, Louisville.

Cholera Infantum; Report of a Case, by Hugh J. McLean, Wilmore.

Malignant Disease of the Uterus, by Louis Frank, Louisville.

A Case of Hematoma of the Vulva Following Normal Delivery; Operation; Recovery, by Isaac A. Shirley, Winchester.

Induction of Premature Labor for Neuro-retinitis Albuminurica to Save the Eyesight, by J. G. Carpenter, Stanford.

Puerperal Eclampsia, by M. C. Cash, Salyersville.

Smallpox and Vaccination, by Albert Bernheim, Paducah.

Exhibition of an Obstetric Outfit, by Henry E. Tuley, Louisville.

Vesico Vaginal Fistula, With Report of a Case, by D. B. Knox, Newton.

Influence of Age and Race in Surgical Diseases, by W. L. Rodman, Louisville.

The Curative Treatment of Hemorrhoids by the Country Practitioner, by J. L. Atkinson, Campbellsville.

Extra uterine Pregnancy, by F. F. Bryan, Georgetown.

The Midwife and Midwifery, by L. C. Wadsworth, Newport. Syphilis, Whence Does it Originate and Where is it Now? by Henry Plummer, Harrodsburg.

Special papers for Discussion: Pathology of Osteomyelitis, by Arch. Dixon, Henderson.

Diagnosis and Treatment, by James B. Bullitt, Louisville.

Pathology and Diagnosis of Diphtheria, by C. W. Aitken, Flemmingsburg.

Treatment of Diphtheria, by S. G. Dabney, Louisville.

Relation of State Boards of Health to Medical Practice, by William Bailey, Louisville.

tired with a competency. Although his name is best known in connection with the laboratory of the Long Island College Hospital, he had many other affiliations such as a Fellow of the Microscopical Society of London, besides being more or less actively identified with the American Geographical Society of New York, the New York Genealogical and Biographical Society, the Long Island Historical Society, the People's Trust Company and the Dime Savings Bank, but most of all does he deserve the grateful remembrance of the medical profession to which he was devotedly attached. He leaves three daughters.

HENRY C. CROUCH, M.D., Denver, Colo., died April 20, aged 40 years. He was graduated from Yale in 1879, represented the United States as consul at Milan from 1886 to 1890, and in the latter year the University of Giessen conferred the degree of Doctor of Medicine upon him. In 1891 he came to Colorado. Dr. Crouch was appointed a member of the State Board of Health in 1892 and bacteriologist both to the State and city boards of health in 1895, holding both positions at the time of his death. From 1893 to 1897 he occupied the professorship of bacteriology in the medical school of the State University.

WILLIAM MEACHER, M.D., Portage, Wis., died April 22, aged 65 years. Dr. Meacher was a member of the board of censors of the Wisconsin Medical Society, an ex-president of the State, the Northwestern Medical and the Central Wisconsin Medical Society. He was a graduate of Rush Medical College, class of 1862, and during the civil war was commissioned assistant surgeon of the Sixteenth Wisconsin. He was at the siege of Atlanta and in the march to the sea with Sherman.

DAVID W. YANDELL, M.D., ex president of the AMERICAN MEDICAL ASSOCIATION, Louisville, Ky., died May 3, after long lingering illness. Further notice will appear in the JOURNAL of next week.

ELLSWORTH D. WHITING, M.D., Rush Medical College, 1897, of the Presbyterian Hospital staff, Chicago, died at Aurora, Ill., April 26, of typhoid fever.

MARTIN VAN BUREN BOGAN, M.D., Washington, D.C., April 19, aged 69 years.—Elizabeth R. Hess, M.D., Iowa City, April 21, aged 54 years.—Benjamin K. Johnson, M.D., Norristown, Pa., April 23.—James A. Leason, M.D., Dillon, Md., April 21, aged 43 years.—H. G. McNaughton, M.D., Albany, N. Y., April 18.—Charles W. Meyers, M.D., Clinton, Iowa, April 21.—Alexander J. Dunne, M.D., Springfield, Mass., April 22, aged 36 years.—Daniel Smicer Forney, M.D., Burlington, Iowa, April 20, aged 90 years, a graduate of Washington University School of Medicine, Baltimore, class of 1828.

BOOK NOTICES.

International Clinics. A Quarterly of Clinical Lectures, etc., etc. Edited by JUDSON DALAND, M.D., J. MITCHELL BRUCE, M.D., DAVID W. FINLAY, M.D. Volume 1, Eighth Series, 1898. Philadelphia: J. B. Lippincott Company, 1898.

Contributors to this volume are as follows: T. McCall Anderson, M.D., J. W. Ballantyne, M.D., Cecil Y. Biss, M.D., Byrom Bramwell, M.D., F.R.C.P., Norman Bridge, M.D., Henry C. Coe, M.D., Charles Greeue Cumston, B. M. S., M.D., Samuel G. Dabney, M.D., Judson Daland, M.D., N. S. Davis, Jr., A.M., M.D., Prof. Hayem, J. O. Hirschfelder, M.D., M. B. Hutchins, M.D., Prof. Jaccoud, Alexander James, M.D., F.R.C.P., I. N. Love, M.D., Herman Marcus, M.D., Prof. Marfan, M.D., Joseph M. Mathews, M.D., Ernest Maynard, B.S., M.D., E. E. Montgomery, M.D., William Oliver More, M.D., Paul F. Mundé, M.D., LL.D., Thomas Oliver, A.M., M.D., A. Pinard, M.D., Thomas R. Pooley, M.D., B. Alexander Randall, M.D., W. O. Roberts, M.D., Albert Robin, M.D., Graham Steell, M.D., Charles G. Stockton, M.D., J. D. Thomas, M.D., Nestor Tirard, M.D., J. S. Todd, M.D., Prof. E. Van Leyden, H. O. Walker, M.D., William H. Wathen, M.D., LL.D.

The volume is well illustrated and gives a fair presentation.

NECROLOGY.

CORNELIUS NEVINS HOAGLAND, M.D., died at his home in Brooklyn, N. Y., April 21, from hepatic trouble. On January 25 he left for a Mediterranean trip and returned on April 5 with cardiac symptoms which culminated in a short and quiet slumber. He was born in Neshanic, N. J., Nov. 23, 1828, but was brought up in Ohio, where his parents removed in 1834 and where, in Cleveland, he received his medical degree from the Western Reserve University. In 1854 he was elected county auditor of Miami County, Ohio, and was re-elected in 1856, which constituted a term of four years. The breaking out of the war found him a private in the Lafayette Blues, a company recruited in Troy, Ohio, and in 1861, in response to the call of President Lincoln for troops, he became its first lieutenant and with them was assigned as Company H, Eleventh Ohio Infantry. In October of the same year he was appointed surgeon of the Seventy-first Ohio Infantry and served as such until January, 1866. He took part in several engagements and was wounded in the breast at Nashville, Tenn. Coming to Brooklyn, N. Y., in 1868, he engaged in business and in 1876 re-

of the clinical teachings of the day on the subjects mentioned in the work.

An American Text-book of Genito-Urinary Diseases, Syphilis and Diseases of the Skin. Edited by L. BOLTON BANGS, M.D., and W. A. HARDWAY, A.M., M.D. Illustrated with 300 engravings and 20 full-page colored plates. Philadelphia: W. B. Saunders, 1898. 8vo. pp. 1230. Price \$7.00.

This voluminous work is thoroughly up to date and the chapters on Genito-urinary Diseases are especially valuable. The illustrations are fine and mostly original. The section on dermatology is concise and every way admirable. We regret to see that the old system of weights and measures has been used instead of the decimal system, but the work as a whole is worthy of all praise.

Chaplo on Insanity. By JOHN B. CHAPIN, M.D., LL.D., Physician-in-Chief, Pennsylvania Hospital for the Insane; late Physician-Superintendent of the Willard State Hospital, New York, etc. 12mo, 234 pages, illustrated. Philadelphia: W. B. Saunders, 1898. Price \$1.25.

This is an admirable manual for those who wish to obtain a general knowledge of the subject without the labor or burden of the study of more voluminous text-books. The essential forms of diseases of mind are well presented, and the work is intended to be for popular as well as scientific reading.

A Laboratory Text-book of Pathology for the use of Students and Practitioners of Medicine. By HORACE J. WHITACRE, B.S., M.D. Illustrated. 8vo. Cl., pp. 172. Philadelphia: P. Blakiston, Son & Co. 1897. [Chicago, E. H. Colegrove, agent.]

This work is not intended as a complete treatise on pathology, but it furnishes the student with an excellent text-book for use in the Laboratory.

Photomicrographical illustrations are used throughout the work and are a very satisfactory method of illustration. None of the more pronounced pathologic lesions are omitted.

Fat and Blood, an Essay on the Treatment of Certain forms of Neurasthenia and Hysteria, by S. WEIR MITCHELL, M.D., LL.D. Seventh Edition. 12mo. Cl. pp. 178. Philadelphia: J. B. Lippincott Company. 1898.

When a book has passed to its seventh edition the most that can be done by the examiner is to record the fact, and to note the changes that have taken place since the preceding edition. The author says, "The present edition like the last has been carefully arranged by my son, Dr. John K. Mitchell. Some changes were made in the sixth edition and a few more have been made now as a result of added years of experience. Some points of treatment have been more fully dealt with. The Chapter on Massage has been wholly rewritten, in order to describe the process according to the methods which on use and observation appear to be the best, and to notice the last physiologic studies and its effects."

Atlas of Internal Medicine and Clinical Diagnosis. By Dr. CHR. JAKOB, of Erlangen. Edited by AUGUSTUS A. ESHNER, M.D., Professor of Clinical Medicine in the Philadelphia Polyclinic; Attending Physician to the Philadelphia Hospital. 68 colored plates, and 64 illustrations in the text. Pp. 260. Philadelphia: W. B. Saunders. 12mo. Cl. Price \$3.00.

This atlas contains a selection of the most important clinical conditions a knowledge of which the practitioner must acquire, and the acquisition is made more simple and easy by its means. We predict a large sale for this work.

Clinical Reports and Notes on Unguentine, Fourth Edition. Paper, pp. 140. Norwich, N. Y. Press of Norwich Pharmacal Co.

This monograph tastily gotten up, contains clinical reports and comments favorable to unguentine. Copy may be had for the asking.

Arsenauro and Mercauro. Paper. Pp. 32. Illustrated. New York: Charles Roome Parmele Co.

This brochure contains clinical records of arsenauero and mercauro as reported in medical journals with several full page plates in colors.

Daydreams of a Doctor. By C. BARLOW, M.D. 12mo. Cloth. Pp. 252. The Peter Paul Book Co. Buffalo, N. Y. 1898.

This work is an incursion into the field of literature from the standpoint of a physician. It is a rather successful attempt of imitating the style of *Ik Marvel* in the *Reveries of a Bachelor*, and will be found very interesting and very instructive. Its style is pleasant and the book will prove an agreeable companion for the doctor when more or less weary by the reading of heavier scientific productions.

PUBLIC HEALTH.

Progress in the Official Organization of Disinfection at Paris.—The Parisian bureau of disinfection has made an important report to the Municipal Council upon the results accomplished under the modernized methods employed for the restriction of infectious disease. From this report it appears that in seven years with a staff which numbers eighty people the organization has carried out in Paris more than 171,000 disinfections, the annual average being at present nearly 40,000. In 1886, before the service was organized, there died in Paris nearly six thousand persons, carried off by epidemic diseases. Ten years afterward, in 1896, the number, which had been gradually falling, fell to below two thousand; that is to say, that three or four thousand human lives were saved every year. Without doubt the works which have been carried out of bringing water straight from the springs have contributed greatly to the amelioration of the sanitary condition of Paris, but disinfection has also played a large part. The total mortality, which was 54,536 in 1892, the date at which the disinfecting service was first organized, fell in 1897 to 46,987, that is to say, an average of 18.54 per 1000 inhabitants in place of 22.47. The principal part of this very considerable diminution in the mortality of Paris is accounted for chiefly by the diminution in zymotic diseases. The mortality from these diseases, which was formerly one-tenth of the whole, fell gradually to one-eighteenth between 1891 and 1895, one-twenty-sixth in 1896 and one-twenty-seventh in 1897. Enteric fever in 1892 accounted for 691 deaths and in 1897 for 231. In 1892 there were 42 deaths from smallpox and only 12 in 1897. In 1892 there were 900 cases of measles and only 811 in 1897. The deaths from scarlet fever, which were 158 in 1892, fell to 76 in 1897. There were 334 cases of whooping cough in 1892 and only 282 in 1897. Finally, diphtheria, which gave rise to 1403 deaths in 1892, was the cause of only 306 in 1897. M. Landrin observed that tuberculosis remained stationary because prophylaxis against this terrible disease, which is accountable for one-quarter of the whole mortality, is not yet a definite part of the social system. He reminded his audience that both the municipal council and the government are ready to make a great effort to fight against tuberculosis. In addition to the measures taken in hospitals and the system of treating the poor at their homes, as well as those unfortunates who are under the care of the Assistance Publique, measures were taken during 1897 by the municipal disinfecting organization with the view of carrying out a more complete and methodical campaign against tuberculosis. The report concludes with the recommendation that measles, which is today one of the most fatal zymotics, should be made a compulsorily notifiable disease.

Progress in the Preparation of Glycerinated Vaccine Lymph in England.—The London *Lancet*, March 5, adverts to an announcement that has been made in some of the medical journals to the effect that the local government board will at once proceed to distribute glycerinated calf lymph to public vaccinators. The statement is evidently premature, for although the board are making arrangements to secure a proper laboratory where the necessary processes of preparing and storing the lymph can be carried out, these arrangements are not yet completed.

There must also necessarily be delay after the laboratory and its staff are in working by reason of the necessity of keeping the glycerinated lymph a sufficient period of time for the destruction of extraneous organisms and for testing the keeping qualities of the lymph. If, as announced by Mr. Chaplin, glycerinated calf lymph is to be available for all vaccinations it is clear that the use of humanized lymph must practically cease, and before this can take effect the department supplying the glycerinated lymph will have to feel confident that it can meet the many demands which will be made on it by supplying in large amount a lymph that can be depended on. We therefore doubt whether any such supply as is needed will be forthcoming for some months to come. But there is reason to believe that such a supply will be issued quite independently of the passing of any vaccination bill. The editor further states that he has received specimens of lymph from the Jenner Institute, prepared and glycerinated in strict accordance with the methods now well known and first advocated by Dr. Copeman. The tubes, it is stated, are only sent out after testing by plate cultivating, and after negative evidence has been obtained of the complete absence of the "adventitious" microbes, as Lord Lister has described them. The calves from which the lymph is obtained are first tested with tuberculin prior to being inoculated. The glycerin used is kept under strict aseptic precautions. As is well known, lymph prepared in this approved way is bacteriologically pure and free from pus producing organisms.

MISCELLANY.

The Sense of Smell in Troubles of the Ears.—Collet has established the fact, with Zwardemaker's olfactometer, that the sense of smell is materially diminished in all disturbances of the ears: least in otitis media and cicatrized tympanum, most in sclerosis.—*Deu. Med. Woch.*, February 24.

Pasteur Institute at Florence.—A Pasteur Institute is to be established at Florence, Italy, for the treatment of rabies, the latter being of common occurrence in Tuscany, where most of the population is engaged in agriculture. Milan, Rome and Naples are already provided with institutes in which the Paster treatment is employed.

A Blow at "Face Specialists."—A bill has been introduced in the New York assembly to put a stop to unprincipled persons who make a business of removing facial blemishes and making dimples. The bill provides that such work may not be done by any but practicing physicians. A fine of \$250 and imprisonment for six months will be the penalty for the first offence, a fine of \$500 and a year's imprisonment for a subsequent conviction.—*Medical News*, April 2.

The Second French Congress of Gynecology and Obstetrics.—The second periodic French Congress of Gynecology, Obstetrics and Pediatrics will be held at Marseilles, France, from October 8 to 15 under the presidency of Professor Pinnard (Section on Obstetrics), Professor Pozzi (Section on Gynecology) and Professor Broca (Section on Pediatrics). All communications should be addressed to Dr. Quirel, general secretary of the Congress, 20 Rue Grignan, Marseilles.

The Prevention of Fire in Lodging Houses.—The New York houses for lodgers are said to number 113, at least that is the number on record in the Department of Health as being operated under an official permit. In consequence of the disastrous fire which recently occurred at one of the Bowery houses a simultaneous inspection was made of the entire number on a given night. The result was quite satisfactory, as only five of the houses were discovered to be conducted in violation of the terms of their permits or the requirements of the lodging-house law.

Swiftwater Biological Laboratory.—Dr. Richard Slee, formerly of Brooklyn, has established at the above named town in Pennsylvania a plant for the production of therapeutic animal products, as antitoxins and vaccines. His laboratories have been planned in conformity with the requirements of the State Board of Health, of which he is an officer. Bovine vaccine will be produced in the form of glycerinated virus in Sternberg bulbs or in capillary tubes, or on ivory points.

The "Strabo" at New York Quarantine.—The Health Officer of the port of New York, Dr. Doty, has detained for disinfection purposes the English coffee steamship, *Strabo*, because of a death by yellow fever on the voyage north. Both the captain and cook were taken with the disease on the way up. The former recovered and was able to resume command of his ship. The cook died and was buried at sea. At St. Lucia the ship was disinfected. As there was no evidence of sickness on board at the time of her arrival in the harbor, Dr. Doty directed that the steamer be disinfected again and then be allowed to proceed.

The Rotation Method of Reducing the Blood Pressure.—Von Wenusch has been testing the effect of fastening a person on a revolving table in a dark room, and finds that the frequency of the pulse and the blood pressure is much reduced by this centrifugalization, which he thinks may find some therapeutic application. The table makes sixty revolutions to the minute, but the patient feels no motion, only a tingling in the peripheral vessels from the accumulation of the blood. *Klin. Therap. Woch.*, February 27.

Telegony.—This term was proposed by Professor Weismann to denote the cases where the female is so far influenced by the first sire to which she bears offspring that the subsequent offsprings to other sires presents some of the characteristics or peculiarities of the first. Early in the century Lord Morton bred from a chestnut mare a quagga hybrid, and the mare afterward produced to a black Arabian horse a filly and a colt marked like the hybrid. In the *Scottish Medical and Surgical Journal*, Dr. J. C. Ewart takes up the subject from the view-point of his own original researches. In 1895 Professor Ewart formed a small stud and commenced various crossing experiments between horses and zebras. He now has five zebra mare hybrids, and the dam of a last year hybrid has recently produced to an Arab horse a foal presenting numerous zebra-like stripes over the croup and loins. He enumerates the explanations of this phenomenon that have been suggested by Sir Everard Home, Herbert Spencer and Weismann, all of which he thinks are highly improbable.

The Antitoxic Action of Nerve Pulp in Strychnin Intoxication announced by Vidal and Nobecourt, is now explained in a disappointing fashion by Thoinot and G. Bronardel, who find that a number of inert substances are also capable of neutralizing the poison, and by the simple mechanism that they absorb and retain its toxic essence so that the filtered fluid contains none of the actual poison, and can be injected with impunity. Nerve pulp, talcum powder, charcoal, etc., were nearly equally effective in thus "neutralizing" the poison. *Presse Méd.*, March 26. They are now investigating whether these conclusions will also apply in any degree to Wassermann's successful experimental neutralization of tetanus with emulsified brain matter injected several hours before the tetanus toxin. *Ibid* JOURNAL, pages 449 and 935.

A Hint to Advertisers.—To our friends in the drug trade and elsewhere, who deal in artistic ways of announcing their products, we may say that an antique glyptic portraiture of Esculapius has recently been discovered and introduced into English literature. In Professor J. G. Frazer's book, on the "Description of Greece by Pausanias," appears a photo illustration of a marble relief showing the medical divinity as found in the Epidaurian sanctuary. The figure of Esculapius is an

eminently dignified one and if properly reproduced in illustration will be quite sure to arrest medical attention, and this is what our friend, the artistic advertiser, is glad to do. The best imprint is to be found in the *Ephemeris Archæologica* for 1896.

Bequests of a New York Physician.—Under the will of the late Dr. Edward C. Seguin of New York City the Academy of Medicine will fall heir to an oil painting of his father, the late Dr. Edward A. Seguin, together with a frame autograph letter dated Dec. 16, 1847, of Pope Pius IX. He leaves to the same institution a bronze medallion of Charcot and a large photograph of Brown-Séquard. All his instruments and appliances for the study of the nervous system and also all books in his library relating to the anatomy and physiology of the nervous system, he leaves to the pathologic laboratory of the Alumni Association of the College of Physicians and Surgeons, provided a special bookcase and drawers are set apart for their keeping and a catalogue of them is made. In case this bequest is not accepted the collection is to be given to the New York Academy of Medicine, also his special collection of monographs and pamphlets on the nervous system and his other books on the same subject.

A "Healtheries" at New York City in May.—From April 25 to May 31 an International Health Exposition will be held at New York in the Grand Central Palace, Lexington Avenue. The New York Household Economic Association and kindred organizations will co-operate with the management of the Exposition, which will embrace everything relating to health, both indoors and outdoors, and illustrate the sanitary and hygienic progress of the century. Mr. Charles E. Wingate is the supervising director. All exhibitions of this description should be encouraged, for they are of distinct benefit: first, in bringing together for comparison the latest sanitary appliances and methods, and second, in educating the public in their use and benefits. The second point is perhaps the most important, because whatever sanitarians may do with regard to the improvement of their science, the resulting benefits to the health of the community must be tardy unless the public is ready to aid in the application of the improved processes. In our own country we have far too few of these exhibitions, and sanitary science would be much benefited if the public were better educated in this matter. *Medical News*, April 16.

Ligatures to Produce Atrophy in Inoperable Tumors have been revived of late, as mentioned in the *JOURNAL*, January 1, page 37, and examination of several of the neoplasms at the death of the patients, five to seven months after the ligatures had been applied, show that ligature of the uterine artery is far superior to ligature of the internal iliac in respect to the hemostasis of the uterus secured. The uterine artery is easily located by its relations to the ureter. A peritoneal incision in front of and parallel to the ureter in the bed of the ovary, discloses the uterine, without fail, at its starting point. In cancer of the uterus the atrophying ligatures seem to diminish the discharges, at least temporarily, but do not conspicuously modify the course of the neoplasm. An interesting point noted is that the ligature was never followed by the formation of a clot, thus confirming in man previous experimental results.—*Presse Méd.*, February 12.

Sixty-six Years Make an "Aged" Person.—The supreme court of Georgia thinks that it would be difficult to designate an exact period of life when one might with certainty be said to have become aged. And, while it concludes that the term "aged" as applied to human beings is not, for all purposes, susceptible of precise definition, and that it is not practicable to arbitrarily fix a period of life at which the condition of being aged may be said to have certainly begun, it holds, in the recent case of *Allen vs. Pearce*, that it is safe to say that a man 66 years old is entitled to an exemption of his property from levy

and sale, under that clause of the constitution of Georgia allowing this right to "every aged or infirm person," and this even though he may be a hale and hearty man. In an English case it has been held that persons 50 years of age are aged, within the meaning of the statute of charitable uses, providing for gifts "for the relief of aged and impotent and poor people."

Egg and Coffee, the New Differentiating Culture Medium.—White of egg poured over raw grains of coffee turns a bright green and bacilli develop readily in it, not affected by the color, but with the peculiarity that each species is surrounded by a zone of some other color, which lasts as long as the colonies retain their vitality. Colonies of meningococcus and pneumococci are surrounded by a zone of bright orange. The staph. pyog. aur. is encircled with a zone of light yellow and slightly liquifies the medium, while around the proteus vulgaris extends a reddish zone. If the colonies are killed the discolored zone gradually returns to its original green. The fresh albumin, 100 grams, is poured over green coffee grains, 20 grams, and set aside for two or three days, then filtered into 10 c.c. test tubes and sterilized by exposure 60 to 65 degrees C. for a couple of hours each day for six days, when it is solidified by raising it to 70 degrees. Acids produce a different effect, so the discoloration by the bacteria is not due to an acid. The green of the albumin is not caused by chlorophyll as the spectrum is quite different, resembling more that of xanthophyll. (Pacinotti and Municchi in the *Gaz. degli Osp. e delle Clin.*, March 13.)

Skin Grafting Case at the Antipodes.—A curious case was tried recently at Sidney, where a woman brought an action for damages against a doctor who had removed fifty-two square inches of skin to graft on a patient who had been severely burned. It must be admitted that this was a rather a large draft on any one's abnegation, and the good lady seems to have regretted her generosity when it was too late. Unfortunately for her, the fact that she was a consenting party was held by the jury to exonerate the doctor, so she is minus both skin and damages. Possibly a claim would lie against the beneficiary, though even a committee of experts would find it difficult to appraise the value of skin per square inch. On any future occasion we would suggest that she stipulate beforehand how much skin she was prepared to "shed." However, the plaintiff appeared to have just cause for complaint, and we are quite unable to approve the conduct of the surgeon who, even by consent, partially flays one person in the interest of another.

Medical Press and Circular.

A Railroad Hospital Car in Belgium.—A modern improvement that Belgium has put upon one of her railway systems is a specially designed and specially built hospital car, which will be available in the case of a serious railway accident. It may also be employed in conveying invalids from one point to another as, for instance, from the inland towns to the health-giving sea-side watering places. The interior of the carriage is divided into a main compartment and two small rooms at the end. In the larger room are twenty-four beds, and each patient lies in front of two small windows which can be opened at will. A movable table can be lowered over each bed. There are lockers in the corridors for ice-chests, provisions and linen. If necessary a part of the saloon can be transformed into an operating chamber. In connection with the hospital is a small chapel for religious services, and the patients will be in charge of a surgeon and nurse. Although primarily designed to meet the wants of the traveling public, this car may be readily adaptable to the needs of injured railroad employees.

Primary Disseminated Sarcomatosis in the Soft Membranes of the Central Nervous System.—F. Svenson has classified the fifteen cases on record. Three were tumors of endothelial origin with endothelial cells, rapid in their development, three and a half

months maximum; five of endothelial origin, in which the cells had lost their endothelial type, course from two months to six years, besides the symptoms indicating pressure there were other morbid manifestations: and seven round-celled sarcomas, average age at death thirteen years, course rapid, from two and a half to twelve months. In his personal case, belonging to the second group, the base of the brain was found dotted with large and small tumors in the pia mater, respecting the nerve substance almost completely, and a single large tumor in the lower part of the occipital and temporal prolongations, distinguished by an alveolar structure, although three kinds of tissue were evident, granular nuclear cells clearly defined, surrounded with a thin layer of protoplasm, ramifying on all sides. These ramifications united with others and formed a myxoma-like tissue. There were also other similar cells without clear outlines. An ependymitis sarcomatosa was also noted. The first manifestations were headaches and convulsions followed by inco-ordination, facial paresis, blindness from papillary stasis, frequent unconsciousness and diminished psychic functions: after six years death in coma, interrupted by convulsions. His article in the *Nordiskt Med. Ark.*, No. 32, 1897, is fluently illustrated.

Pill-dipper Patent Void.—Letters patent No. 389,455, issued by the United States, Sept. 11, 1888, to John B. Russell, was for a "device for holding and dipping pills," etc. This device has been described as consisting of a bar having a number of hollow seats for the reception of pills, which bar is adapted to be connected with an exhaust or sucking apparatus, so that the pills to be dipped are held to their seats by atmospheric pressure while being dipped. The specification of Russell's patent contained the following: "Pills are now dipped in gelatin by the use of what is known as a 'needle bar,' viz., a bar in which are set a number of needles. The pills are impaled on these needles, partially dipped, are allowed to dry and then removed from the needles, usually by spring fingers, and the uncoated portion dipped. This, of course, makes a hole in each pill, and requires considerable manipulation. My invention consists in holding the pills on the dipping mechanism by atmospheric pressure, and I do this by maintaining a partial vacuum behind the pills when in position." Unfortunately, however, for the validity of the patent, the United States circuit court of appeals holds, reversing the circuit court, Frederick R. Stearns & Company vs. Russell, February, 1898, that, notwithstanding the utility and success of the application of the device to pill-dipping, this was but a new application of an old device and hence not patentable.

Goat's Milk "Cures" in Switzerland.—Dr. Irving Richman, of the Consular service, writes from St. Gall, Switzerland, that he has been able to find few specialty-cures for the treatment of the sick by the use of goat's milk in that country. There would seem to be a few, if any, purely goat-milk cure establishments in the country. At all the mountain resorts and "*Kurorte*," goat milk is provided as well as the milk of the cow. Goat's milk is believed to be immune to tubercle and more nourishing than any other milk, and hence is often prescribed for patients with a consumptive tendency. I am told that, except for the above mentioned qualities, goat's milk is of no greater value than the milk of the cow. In fact, it is stated that the latter, when boiled, is quite as good as the milk of the goat; inasmuch as many persons dislike to drink boiled milk, fresh goat milk is prescribed instead. In French Switzerland, at Lausanne, Vevey, and other places, boys go from house to house with a half dozen goats, supplying milk as it is called for by milking the animals on the premises. The price of goats is from \$5 to \$8 each. The canton of Appenzel, in northeastern Switzerland, is particularly noteworthy for "*Kurorte*," whence is dispensed the milk of the cow and the goat, the towns of Heiden and Appenzel being the principal points.

Carne Liquida, a new Uruguayan Food Product.—The *Consular Reports* inform us that 200,000 cattle are slaughtered yearly in Uruguay in the production of meat extracts. Taking into consideration that 100 pounds of good, solid meat yields only 2½ pounds of extract, the immense loss of alimentary substance to the world may be imagined, and therefore from a standpoint of national economy, as well as food, the production of meat extract must be considered as a great wastage of alimentary matter. No doubt this fact has given rise to the various and extensive experiments made in the field of chemistry everywhere, as well as in the great meat-producing country of Uruguay, and beyond question has also led to the discovery made by the Uruguayan chemist, Dr. Valdes Garcia, of the so-called "*carne liquida*" (liquid or fluid meat), in which he endeavors to combine the qualities of the extract of meat with the nourishing properties of the meat itself. This is already the third in prominence of the meat products of the country. The success of this comparatively new product has been so far very satisfactory, as regards the purposes for which it was intended. It is building up a considerable reputation the world over, and is already called for by merchants of Europe, Africa, America, and Australia, so that the factory is pushed to supply the demand. This very digestible and nourishing aliment is recommended especially to hospitals by the various chemists who have analyzed it.

Dentistry Practice Kind of Certificates Required in Maryland.—An interesting point of statutory construction is involved in the decision of the court of appeals of Maryland, which was handed down Feb. 10, 1898, in the case of Knowles against State. An 1896 act of that State declares that it shall be unlawful for any person to practice dentistry in the State without first obtaining a certificate as provided by the act, while section 12 thereof excepts from its operation certain classes of persons, providing, among other things, that nothing therein shall be construed as to interfere "with persons holding certificates issued to them prior to the passage of this act." In this case, after a conviction in the criminal court of Baltimore City for unlawfully practicing dentistry without having obtained from the State Board of Dental Examiners a certificate as required by the foregoing act, appeal was taken, contention being urged that the trial court had erred in rejecting as evidence a certificate of qualification and registration issued by the Board of Dental Examiners of the State of Ohio. But the court of Appeals of Maryland takes the position that it was the intention of the legislature to confine the act of 1896 in its application to certificates which had been issued by the Dental Board of that State, under article 32 of the Code of Public General Laws, and to save all certificates which had been previously issued thereunder, without giving the act any extra-territorial force, especially as its language, taken in connection with the previous legislation on the subject, shows conclusively that the act refers only to certificates issued by the Board of Dental Examiners of Maryland, and not to those issued by other States. For these reasons, it holds that there was no error in the rejection of the testimony offered in presenting the Ohio certificate.

Postponed Impregnation.—A rather puzzling class of cases for obstetricians is that of delayed conception. De Koninck has, in the *Revue Médicale*, October 30, analyzed about 400 cases of primiparous labor in wives married for several years and relatively mature. He favors the thirtieth year as the earliest proper to be included under the term of "maturity," or the *primipares agées* of the French writers. It appears that in a genuine uncomplicated case of delayed impregnation the advent of the catamenia is always found to have occurred late in youth. Out of 401 such cases menstruation was retarded till 20 in 39, till 24 in 4, and till 26 in 1. As to the retarded first pregnancy, such complications as abortion, ectopic gestation, twins and

special renal mischief, are relatively frequent. Above all, lingering labor is especially common, statistics even exceeding guesses and *a priori* reasoning in this respect. In 12 out of 17, noted by De Koninck, labor lasted from forty to fifty hours, the remaining labors being yet longer; one exceeded ninety hours. Feebleness of uterine contraction is absolute from first to last, and independent of any obstetrical combination. They also cause far more physical and mental exhaustion than the vigorous contractions of a young uterus, and at the same time are more painful. There are discrepancies in the "pains" seen in mature primiparæ of the same age, probably homologous with the great variations in the age of menopause observed in otherwise normal women. The uterus may be older in one woman aged 35 than in another of the same age. The forceps and other obstetrical operations are often required in the mature. Most of the above facts are easily explained. The excess of male infants borne by mature primiparæ (30 per cent.) is a less explicable phenomenon. Hecker considers the predominance of male infants as a specialty of all primiparæ, but Rumpe turns attention to the fact that in a family of children the predominance of males is commoner the further the mother is from her first menstrual period.

When Doctors are Balld.—An important precedent, of particular interest to physicians and surgeons, is established by the decision rendered by the appellate division of the supreme court of New York, in the case of Yaggle vs. Allen, January, 1898. This was an action brought against two doctors, father and son, for negligently causing the death of Frederick Yaggle, who had called at their office to have a shoulder set, that was subject to dislocation. After this operation had been performed, and while still under the influence of the chloroform, or while recovering from its influence, or just after recovering from its influence, as to which there was a conflict in the evidence, but while still in the operating-chair, Yaggle suddenly expired. There were only three persons present at the time of the administration of the chloroform to, and the performance of the operation upon, the deceased, viz., his son and the two doctors. The son and the doctors were in direct conflict in regard to the amount of chloroform used, the manner of its administration, and several other details, which were relied upon as evidence of the negligent and unskilful manner in which the operation was conducted. Moreover, the only physician sworn on behalf of the plaintiff testified, from the plaintiff's own evidence as to what took place, that he was unable to state the cause of death. One of the physicians sworn for the defendants stated that he was unable to give the cause of death, and two others stated that, from the condition in which the lungs were found, death was not the result of suffocation or strangulation, but, in their opinion, was produced by calcareous degeneration or fatty change of the vessels of the heart. Under such circumstances, which it distinguishes from a case of conflicting expert evidence, the appellate division holds that a jury could not determine the cause of death, because neither juries nor courts are permitted to render verdicts or judgments upon guesses or surmises. For these reasons it reverses a judgment that was rendered in the court below against the doctors, and grants a new trial.

Restates the Law Relating to Malpractice.—The court of appeals of New York says, in the case of Pike vs. Honsinger, March 1, 1898, that the law relating to malpractice is simple and well settled, although not always easy of application. A physician and surgeon, by taking charge of a case, impliedly represents that he possesses, and the law places upon him the duty of possessing, that reasonable degree of learning and skill that is ordinarily possessed by physicians and surgeons in the locality where he practices, and which is ordinarily regarded by those conversant with the employment as necessary to qualify him to engage in the business of practicing medicine and surgery.

Upon consenting to treat a patient, it becomes his duty to use reasonable care and diligence in the exercise of his skill and the application of his learning to accomplish the purpose for which he was employed. He is under the further obligation to use his best judgment in exercising his skill and applying his knowledge. The law holds him liable for an injury to his patient resulting from want of the requisite knowledge and skill, or the omission to exercise reasonable care, or the failure to use his best judgment. The rule in relation to learning and skill does not require the surgeon to possess that extraordinary learning and skill which belong only to a few men of rare endowments, but such as is possessed by the average member of the medical profession in good standing. Still, he is bound to keep abreast of the times, and a departure from the approved methods in general use, if it injures the patient, will render him liable, however good his intentions may have been. The rule of reasonable care and diligence does not require the exercise of the possible care, and, to render a physician and surgeon liable, it is not enough that there has been a less degree of care than some other medical man might have shown, or less than even he himself might have bestowed, but there must be a want of ordinary and reasonable care, leading to a bad result. This includes not only the diagnosis and treatment, but also the giving of proper instructions to his patient in relation to conduct, exercise and the use of an injured limb. The rule requiring him to use his best judgment does not hold him liable for a mere error of judgment, provided he does what he thinks is best after careful examination. His implied engagement with his patient does not guaranty a good result, but he promises by implication to use the skill and learning of the average physician, to exercise reasonable care, and to exert his best judgment in the effort to bring about a good result.

Bellevue Hospital Overcrowded. A telegram from Albany, N. Y., shows that the State Board of Charities are about to report certain serious defects at the Bellevue Hospital. The cellars especially of that institution have not been properly cared for. The wooden floors were found in a very bad condition, the boards being rotten and broken. They contained several old and leaky ice boxes. The exhaust from a service steam pipe enters the sewers within ten feet of some of the ice boxes and ends there. Several of the cellars are used for storage purposes, but there is little system, and their use for this purpose should be discontinued. In the carpenter shop there were several lighted candles unprotected by wire screens. Heaps of shavings on the floor suggested the danger of fire from an overturned candle. Recommendation was immediately made that the carpenter shop be removed from the cellar. Other cellars were occupied as eating places for self committed men who work a few days for their board. In one of these were several dining tables made of rough wood, one of which at least was uncleanly. An adjoining cellar was used as a dormitory for homeless men. It contained thirty-two beds. It was very dark, badly ventilated and out of repair; unfit for decent human habitation, and greatly overcrowded. Preliminary measurements show that the lawful amount of cubic space is not given the inhabitants of the cellars. The same conditions apply to a cellar room used as a dormitory for male help. The cellars were found in a condition that must be dangerous to the health of the inmates of the upper floors, as well as unfit for occupation. The orderlies' dining room, in the basement, was a dismal apartment in bad order. The alcohol ward overcrowded. In the sitting-room of that department were twenty men, convalescent, and for want of space several of them were obliged to lie on the floor. The female ward was also overcrowded; there were eighteen inmates and only fourteen beds.

Insane Person not Deprived of Liberty Without Due Process of Law.

—There are many cases, says the supreme court of errors of Connecticut, in which a man may be restrained of his liberty

by any one and without warrant. These have always been holden not to infringe the constitutional provision which says that no person shall be deprived of his life, his liberty, or his property without the due process of law. Thus, one who is prevented from injuring another can not justly assert that he has himself been deprived of any right. And an insane person, whose going at large is dangerous to others or to himself, and who is restrained, can not maintain that he has been deprived of any right or that he has suffered any injury. But a private person can act in restraining another of his liberty only in an emergency, and then only at his peril, the peril of being unable to prove the existence of the emergency which is his justification. So the court goes on to say in *Porter vs. Riech*, January, 1898, that a wise administration of government does not leave it to private persons to decide when these restrictions shall be exercised, but statutes are passed which directly name or authorize a municipal board to appoint some one to judge of the emergency and direct the performance of those acts which any individual might do at his peril without any statute, and where private persons might not be willing to take the hazard. Such a one as is so named or appointed is the agent of the law and incurs no personal liability. Statutes of this kind, and in many States, the court adds, have been upheld, and so far as it knows without exception. Upon this basis the court especially holds that a statute naming the judge of probate in each district as the agent of the law to determine whether such conditions exist as make it necessary to confine a person supposed to be insane for a temporary period, as pending proceedings for a hearing and examination does not violate any constitutional provision, but is clearly within the police power of the State.

The "Fango" Treatment.—According to the correspondent of the London *Lancet*, March 5, at Vienna, this subject has recently been discussed in one of the medical societies of that city. The "fango treatment" consists in the therapeutic use of a kind of mud obtained from the five lakes of Bataglia, fango being the ordinary Italian word for mud. The substance in question forms a grayish-brown homogeneous mass which adapts itself to the body like a plaster-of-Paris bandage, it retains its heat for a longer time than any poultice does, and it has the advantage that it does not cause the rashes which were brought out by moor (a kind of peat). It contains abundance of oxid of iron, salts of calcium and magnesium, silicic acid and a little organic matter. In the paper on the application of fango read by Dr. Rufschnaiter at the last meeting of the Vienna Medical Society he stated that the affected part of the body is plastered with it and covered with a cloth. At the commencement its temperature ought to be 42 degrees C. (106.6 F.), and may be increased to 54 degrees C. The application lasts twenty-five minutes and produces copious perspiration without any increase of either the respiration or the pulse-rate, and there are no symptoms of weakening of the heart such as result from bathing in water, but the temperature may rise 1.5 degrees C. (2.7 F.) Analysis shows an increase of the nitrogen and the uric acid excreted and a diminution of the water in consequence of the diaphoresis. Fango may be applied over extensive surfaces without producing congestion; it acts as a diaphoretic, as a derivative in hyperemia of the internal organs, as an anodyne in neuralgia and rheumatism, and as an absorbent in joint affections and chronic endometritis.

Experiment Upon Dead Body Not Satisfactory.—The judgment for \$1,741.66 recovered in the malpractice case of *Hastings vs. Stetson* was affirmed by the supreme judicial court of Maine, January, 1898. The evidence tended to show that the plaintiff having suffered a subglenoid dislocation of his right shoulder on November 6, called in the defendant, who failed to discover the dislocation until the twelfth day after the injury. This leads the court to hold that the jury were justified in finding the defendant guilty of negligence in the case, for if he had

exercised the care the law requires of a surgeon, it declares he could and ought to have ascertained the fact of dislocation before the lapse of twelve days. But, it says, he was responsible only for the consequences of that negligence. The dislocation was reduced on November 20 by another surgeon. Nearly complete paralysis of the arm and hand had resulted before the reduction. The plaintiff contended that this was caused by the head of the humerus resting upon and pressing the brachial plexus, a network of nerves in the armpit, for twelve days; and that the defendant's negligence in failing to reduce the dislocation for that length of time caused the paralysis. The defendant, on the other hand, maintained that the head of the humerus, in that kind of dislocation, does not and can not rest upon the brachial plexus, and that the paralysis was the result of the blow which dislocated the shoulder, the head of the bone, in its progress from the socket, lacerating the nerves of motion and sensation which supplied the arm. Many experts in surgery and nerve troubles were examined. Some of them said that, in a subglenoid dislocation of the shoulder the head of the humerus can not rest upon or press injuriously the brachial plexus; that it is an anatomic impossibility; that an experiment upon a dead body demonstrates this; while others said that in that dislocation the head of the humerus would rest upon the brachial plexus: while still others said that in such a dislocation the head of the humerus does not ordinarily rest against the brachial plexus, though it sometimes does, but not frequently. The experiment upon a dead body, the court declares not satisfactory, as there must be a difference in the action of a living sensitive muscle from that of a dead one. And, while the experts were likewise divided as to the cause of the paralysis, the court holds, particularly as it came on gradually for several days after the injury, that the long delay before the dislocation was reduced was the proximate cause of the paralysis: that the defendant was liable for that delay, and that the award of damage therefor could not be said to be too large.

Did the Plague Exterminate the Hellenic People.—A writer in *Lippincott's Magazine* advances the theory that the Greek nation, of the classic period, was wiped out by the plague in the eighth century; and that therefore, the modern Greek is not a Greek at all. He says that the classic Hellene, the typical Greek of antiquity as depicted in sculpture and described in poetry was tall and powerful. So peculiar to his race was his nose that the occasional occurrence of the same kind of nose among modern nations is called Grecian. No other nation, ancient or modern, shows this nose except in rare and sporadic instances. From the Greek sculptures we are led to believe that practically all ancient Greeks had this nose. The ancient Greek was a blond. His hair was of tightly clinging reddish curls. His eyes were blue. The modern Greek possesses none of the foregoing physical characteristics save the curly hair, which is dark. Indeed, no Indo-European nation is a more complete contrast to the general conception of the ancient Greek type. Observing these things it is not strange that a number of German scholars declared that the modern Greek is not a Greek, and that the ancient Greek has passed from the earth, well nigh as extinct as the dodo. At first thought the evidence would seem to prove this theory conclusively. Not only does the modern Greek differ in physical characteristics from the type of ancient Greeks as generally accepted, but there are historical grounds for believing that there is no kinship between the two. In the eighth century a plague devastated Greece, Slavs and Albanians emigrated to fill the depopulated regions. This plague is supposed to have caused the disappearance of the Greek population and the substitution of Slavs and Albanians.

A Distinguished Saltarist of Scotland.—The *Scalpel* for February contains a portrait, with life-sketch, of Sir William Ten-

ant Gairdner, M.D., a prominent Glasgow member of the British Medical Association, a physician to her Majesty in Scotland, professor in the Glasgow University in the Theory and Practice of Medicine for over thirty years, and member of the General Council of Medical Education and Registration representing his University. In 1848 he succeeded that pathologist and author so well known and admired by Americans. Dr. Hughes Bennett, as Pathologist at the Edinburgh Royal Infirmary, where he remained nine years until called to Glasgow. In 1863 he became the health officer for Glasgow, and his accomplishments in the sanitary field lost nothing in comparison with his deeds in the less important duties of teaching and medical politics. This last appointment was accepted with some hesitation, but Sir William Gairdner has since on many occasions borne witness to the great influence for good which the experience gained in that office has had upon his career as a clinical physician and as a teacher of medicine. The sanitary condition of Glasgow at that time was most deplorable. In some parts there was such great overcrowding that nearly 1,000 persons lived upon an acre of ground. The habits of the people were often extremely filthy, and the possibility of cleanliness was too often denied to them by the faulty construction of the enormous tenement houses in which they dwelt, and by the insufficient supply of water, which in any case was of doubtful purity. The prevalence of typhus fever was only an index of the numerous other preventable diseases produced or fostered by insanitary surroundings, but having enlisted the support of the lay officials of that day, an immense transformation was worked under the Glasgow City Improvement Act, and when the great epidemic of cholera reached Glasgow so many improvements had been effected, and public opinion had been so completely won over, that the city was able to face it without panic, and the citizens showed no disposition either to conceal or to exaggerate individual cases of diarrheal disease. As a matter of fact, Glasgow was able to show a death-rate from cholera very much less than that of any other large town in Scotland, except Paisley, which had been the first to adopt similar precautions. Not the least of the services which Sir William Gairdner rendered to the city of his adoption was that he was able, when he resigned the office of medical officer, to point out as his successor Dr. J. B. Russell, whose name is known the round world over as a sanitarian indeed in whom there is no guile, with his whole soul in his work, and an ample Scottish brain to co-ordinate it. On New Year's Day of 1898 Dr. Gairdner received his latest title of honor, having been designated by his Queen to be a knight, with the right to use K. C. B. after his name. He is also the Dean of the Medical Faculty of his University.

Bequests to Brooklyn Institutions.—Under the will of the late Mrs. Charlotte Buck, of Brooklyn, the City Hospital and the Long Island College Hospital will each receive \$5000. Also, under codicil the Brooklyn Eye and Ear Hospital has the reversion of an equal amount, while other donations will eventually reach about twenty more charitable homes and societies, the aggregate of which is about \$340,000.

Many Returns of the Day.—The University of Pennsylvania owns as one of her worthy sons, Dr. Samuel C. Busey of Washington, whose class was that of 1848. The Doctor recently celebrated the golden anniversary of his graduation as Doctor of Medicine, as we published at the time. Among the out-of-town guests were Dr. Jacobi of New York, Dr. Pepper of Philadelphia, Dr. Blackader of Montreal, and Drs. Kelly and Hurd of Baltimore. It may be added that Dr. Busey's connection with our Association was only five years later than the date above given. He was one of our vice-presidents in 1876.

Medical Officers of the Asiatic Fleet.—The following is the list of medical officers attached to vessels of the U. S. Navy under command of Admiral George Dewey, who won the great naval victory at Manila May 1, 1898: *Olympia*, flagship: Medical inspector, A. F. Price; passed assistant surgeon, J. E. Page;

assistant surgeon, C. P. Kindleberger. *Raleigh*: Surgeon, E. H. Marsteller; assistant surgeon, D. N. Carpenter. *Boston*: Surgeon, M. H. Crawford; assistant surgeon, R. S. Blakeman. *Baltimore*: Passed assistant surgeon, F. A. Hessler; assistant surgeon, R. K. Smith. *Concord*: Passed assistant surgeon, R. G. Broderick. *Petrel*: Passed assistant surgeon, C. D. Brownell.

A Combatant Medical Man.—Captain Leonard Wood, Assistant Surgeon, U. S. A., for some time past on duty as assistant to the attending surgeon, Washington, D. C., has been granted authority to raise a regiment of volunteer mounted riflemen, to be organized under section 6 of the Act of Congress approved April 22, 1898. He has been directed by war department orders to proceed to Muscogee, Indian Ter.; Guthrie, Oklahoma: Santa Fe, N. M.; Prescott, Ariz.; Carson City, Nev., and Salt Lake City, Utah, to expedite recruiting, examine the volunteers as to their physical qualifications and muster the accepted recruits into the United States service. It is understood that he will be appointed colonel of this regiment of "rough riders," and that the present Asst. Secretary of the Navy, Mr. Theodore Roosevelt, will become its lieutenant-colonel. There is no particular or essential reason why a medical man may not at least succeed as well as those entering the volunteer service from any other profession or trade, but heretofore the legal profession have had a monopoly of the commissions in the volunteer service.

Mustering in of Volunteer Medical Officers.—In the instructions just published by the War Department for the guidance of officers assigned to the duty of mustering into the United States service the volunteers who respond to the call of the President it is stated that during the organization of a volunteer regiment, its medical officers may be mustered in at any time to aid in recruiting the regiment; but before being mustered they will be required to pass a satisfactory examination as to character and professional ability before a board of army or civilian surgeons, or both, designated by the Surgeon-General of the army. It is provided also that if there be no medical officers duly appointed present, the mustering officer on consultation with the regimental commander, will select and engage the services of one or more physicians having diplomas, and of well established capacities and character, to assist him in inspecting the officers and men to be mustered, and so attend upon and accompany the troops on their march till relieved by others regularly appointed.

To Medical Officers of the Army.—Surgeon-General Sternberg has issued a circular of instructions to medical officers of the army giving directions for obtaining the best sanitary conditions in camp, and for protection against malarial and yellow fevers. It reads as follows:

In time of war a great responsibility rests upon medical officers of the army, for the result of a campaign may depend upon the sanitary measures adopted or neglected by the commanding generals of armies in the field. The medical officer is responsible for proper recommendations relating to the protection of the health of troops in camp or in garrison, and it is believed that as a rule medical officers of the United States Army are well informed as to the necessary measures of prophylaxis and the serious results which infallibly follow a neglect of these measures, especially when unacclimated troops are called on for service in a tropical or semi-tropical country during the sickly season. In Cuba our army will have to contend not only with malarial fevers and the usual camp diseases, typhoid fever, diarrhea and dysentery, but they will be more or less exposed in localities where yellow fever is epidemic and under conditions extremely favorable for the development of an epidemic among unacclimated troops. In view of this danger, the attention of medical officers and of all others responsible for the health of our troops in the field is invited to the following recommendations: When practicable camps should be established on high and well drained ground not previously occupied. Camps should be changed to fresh ground every ten days or oftener. Sinks should be dug before a camp is occupied, or as soon after as practicable. The surface of fecal matter should be covered

with fresh earth or quicklime or ashes three times a day. New sinks should be dug and old ones filled when contents of old ones are two feet from surface of ground. Every man should be punished who fails to make use of the sinks. All kitchen refuse should be promptly buried and perfect sanitary police maintained. Troops should drink only boiled or filtered water and coffee or tea (hot or cold), except where spring water can be obtained which is pronounced to be wholesome by a medical officer. Every case of fever should receive prompt attention. If albumin is found in the urine of a patient with fever it should be considered suspicious (of yellow fever) and he should be placed in an isolated tent. The discharges of patients with fever should always be disinfected at once with a solution of carbolic acid (5 per cent.) or of chlorid of lime (6 oz. to gallon of water) or with milk of lime made from quicklime. Whenever a case of yellow fever occurs in camp the troops should be promptly moved to a fresh camping ground located a mile or more from the infected camp. No doubt typhoid fever, camp diarrhea and probably yellow fever are frequently communicated to soldiers in camp through the agency of flies, which swarm about fecal matter and filth of all kinds deposited upon the ground, or in shallow pits, and directly convey infectious material, attached to their feet or contained in their excreta, to the food which is exposed while being prepared at the company kitchens or while being served at the mess tent. It is for this reason that a strict sanitary police is so important. Also because the water supply may be contaminated in the same way or by the surface drainage. If it can be avoided, marches should not be made in the hottest part of the day, from 10 A.M. to 5 P.M. When called upon for duty at night or early in the morning a cup of hot coffee should be taken. It is unsafe to eat heartily or drink freely when greatly fatigued or over-heated. Ripe fruit may be eaten in moderation, but green or over-ripe fruit will give rise to bowel complaint. Food should be thoroughly cooked and free from fermentation or putrefactive changes. In decidedly malarious localities from three to five grains of quinin may be taken in the early morning as a prophylactic, but the taking of quinin as a routine practice should only be recommended under exceptional circumstances. Light woolen underclothing should be worn, and when a soldier's clothing or bedding becomes damp from exposure to rain or heavy dew the first opportunity should be taken to dry it in the sun or by fire.

Typewriters' Cramp.—Sufferers from writers' cramp are, in the majority of cases, quite able to produce manuscript by means of a type-writing machine, but an instance in which this resource failed is recorded by Dr. F. Hampson Simpson in the *Birmingham Medical Review*. He states that he is not acquainted with any authentic record of a similar case, although he has recently met with two examples of what was called typewriters' cramp; one of these patients, however, seemed to suffer from neuritis and the other from pain and fatigue in the right hand unaccompanied by muscular weakness or spasm. The patient is a muscular man, 33 years of age. He became a clerk when 18 years old and then wrote with a pen on an average from seven to eight hours daily. In March, 1889, that is, after about seven years of this employment, the initial symptoms of writers' cramp declared themselves and at the end of three months all the fingers of the right hand were invaded by spasm, which seriously interfered with writing. In 1889 he learned to use the typewriting machine and he commenced learning to play the harp, but after a few months he found that playing brought on cramp, affecting the right hand generally, more especially the first and second fingers, so that he gave up the harp at the end of 1890. For three years he was at sea as interpreter on board a transatlantic steamer. In January, 1897 he entered an office as typewriter, but was only engaged in working the machine for two or three hours daily. Toward the close of one of the days at the end of February, whilst at work "typing," his right index finger became bent by cramp. From this time on, a repetition of the cramp occurred toward the evening of each day, a slight involuntary flexion at the wrist being superadded, and in less than a month the exaggeration of the spasm led him to substitute the middle of the index finger; six or seven days later this middle finger also became the seat of similar spasm. Dr. Simpson observed very little tendency to spasm

in the operating finger of the right hand during the early portion of a day's work, but after about two or three hours typing the index finger of the right hand became very fatigued and to the flexion of the finger and wrist incidental to striking the keys there was superadded a spasmodic contraction which overflexed those parts. This did not appear to seriously impair the precision of his touch and an inspection of his typewritten work revealed no objective evidence of the spasm in the right finger. It was suggested that he should strike the keys with a little hammer or percussor and he employed this with much benefit and relief for some little time, but the cramp now effects the whole forearm. He has been a pianist for many years and his piano playing is not in the least interfered with by any spasm.

Colleges.

THE SIOUX CITY COLLEGE OF MEDICINE, Sioux City, Iowa, graduated a class of twelve on April 5.—At the commencement of the Medical Department of Fort Worth University, Texas, April 7, twenty-one were graduated.—The graduates from Baltimore Medical College, April 21, numbered 144.—Buffalo University had sixty-three graduates in its medical department, April 26, and the recent commencement of the Toledo (Ohio) Medical College added twenty-seven to this year's medical graduates.

Societies.

The following meetings are noted:

Connecticut.—The 106th annual of the Middlesex Medical Association, Hartford, April 28; Tolland County Medical Society, Hartford, April 19.

Illinois.—Chicago Medical Society, May 4; District Medical Society of Central Illinois, Pana, April 26.

Indiana.—Wabash County Medical Society, Wabash, April 21.

Maryland.—Baltimore County Medical Association, Baltimore, April 21.

Massachusetts.—Hampden District Medical Society, Springfield, April 19; Middlesex South District Medical Society, Watertown, April 21.

Missouri.—Linn County Medical Society, Brookfield, April 19.

New York.—Syracuse Academy of Medicine, April 19.

Pennsylvania.—Blair County Medical Society, Altoona, April 21; Carbon County Medical Society, Mauch Chunk, April 22; Columbia County Medical Society, Blinnsburg, April 19; Franklin County Medical Society, Chamberburg, April 19.

Philadelphia.

THE EXAMINATIONS before the Pennsylvania State Board of Medical Examiners and Licenses will begin at 2 P.M., June 14; they will be held both in this city and in Pittsburg. Dr. H. G. McCormick of Williamsport is President, and Dr. Wm. S. Foster of Pittsburg, Secretary, for the current year, of the Board representing the Pennsylvania State Medical Society, which the daily papers seem to take a special delight in designating by the Hahnemannian epithet of "allopathic," in order to distinguish it from the homeopathic and eclectic examiners on the State Board.

THE WOMAN'S MEDICAL COLLEGE OF PENNSYLVANIA, in order to raise money for the new laboratories, decided to give a series of entertainments of a popular character, the first of which was at the Academy of Music on the 25th ult. Yeaye, Marteau, Gerardix and Lachaume, were the principal artists.

THE WAR FEVER has broken out among the students at the colleges, and, on Friday night, last week, about 500 University men, headed by a band of music, had a street procession. The Medico-Chirurgical College men to the number of over 400 also marched down Chestnut street with flying colors and drums beating in military style, displaying much enthusiasm.

THE COUNTY MEDICAL SOCIETY at its business meeting held

on the 20th ult., received the report of the committee appointed to wait upon the Mayor of the city to urge upon him and upon City Council the necessity of taking immediate steps to secure filtration of the water-supply of the city. The committee consisted of Drs. Solomon Solis Cohen, Edward Jackson, Wm. W. Welch and James Tyson. The language of the report reflected the state of mind of the community on the almost criminal delay in providing the remedy appealed for. The Society adopted the following as the sense of the meeting:

"Resolved, By the Philadelphia County Medical Society that the public safety demands the immediate enactment of such legislation as may be necessary to authorize the construction, maintenance and operation, under public ownership and control, of a proper filtration system."

THE WOMEN'S HEALTH PROTECTIVE ASSOCIATION has handed over to the trustees of the proposed Hospital for Infant Diseases, the sum of \$2,000, the proceeds of a recent entertainment held in this city.

THE PHILADELPHIA COUNTY MEDICAL SOCIETY held a very interesting meeting on April 27. Dr. Judson Daland demonstrated the methods of determining the percentage of red blood cells and hemoglobin, with remarks on their value. Dr. S. E. Solly of Colorado Springs read a paper, by invitation, on "The Blood Changes Induced by Altitude and Their Practical Value." The discussion was opened by Dr. E. O. Otis of Boston, followed by Roland G. Curtin, A. E. Taylor, J. P. C. Griffith, F. P. Henry, J. B. Walker and others.

THE PATHOLOGICAL SOCIETY listened to an address by Dr. F. B. Mallory, assistant professor in the Medical School of Harvard University, at its meeting held on April 28. Dr. Mallory's subject was "A Histologic Study of Typhoid Fever." After the exercises were concluded Dr. Mallory was a guest at a reception given in his honor at the University Club, which was largely attended by the profession.

DR. CHARLES W. BURR has resigned from the chair of neuropathology in the Philadelphia Polyclinic on account of pressure of other engagements.

YELLOW FEVER IN CUBA. — Dr. John Guiteras recently spoke (Press) of the danger necessarily arising from the occupation of Cuba by the United States troops. A great deal has been recently said of what is termed "individual precautions" against yellow fever while in an infected district, which Dr. Guiteras thinks is almost useless in time of war. He said that the disease ought not to be treated from the standpoint of the individual but from the standpoint of the mass. Possibly the most important measure to be exercised by the army would be general measures affecting the distribution of troops, the manner and place of landing, the location of distributing centers of supplies, and the selection of sites for the establishment of camps. The Island of Cuba is usually free from the disease till the middle of June, when it continues until the middle of October, being worse during the months of August, September and October. Outside of the large seaport cities the climate is most pleasant, malarial fevers and dysentery not being more prevalent than during the civil war. The interior of the island is free from the disease, while Havana and other seaport cities are the danger spots of the disease and always infected. Another important factor in the proper protection of the troops is the shipping of all food supplies from the United States. Dr. Guiteras holds the belief that the whole island could be kept free from the disease the year round by means of proper sanitary measures, and that the island has always been a menace to the United States owing to the lack of proper precautions maintained under Spanish misrule.

MEDICAL COLLEGES OF PHILADELPHIA will all furnish their quota of men and trained nurses ready to go to war. It is gratifying to state that if their services are needed a full quota of physicians will be sent out by the faculty and students of the medical colleges of this city. Coach Woodruff, who began organizing a company some time ago at the University of Penn-

sylvania, has extended the invitation to other colleges and now has almost enough men to form two regiments. A number of students in the medical department have passed final examinations preparatory to going into camp. Dr. Martin H. Williams, Chief of the Surgical Clinic at Jefferson Medical College, with four other physicians of the staff, eight trained nurses and a directress will offer their services and if need be will take charge of a hospital in Cuba. It is their intention to be an organized body and to work as such wherever placed. None the least enthusiastic are the faculty, class and trained nurses of the Medico-Chirurgical College, who have held an enthusiastic meeting in the clinical amphitheater and a large delegation have decided to answer the nation's call. Resolutions were adopted offering the services of the staff and the beds of the hospital free of charge. The trained nurses have also volunteered, so that it may be said that Philadelphia if called upon will do her full duty toward rendering first aid to the injured.

PHILADELPHIA COUNTY MEDICAL SOCIETY FOR FILTRATION.

—At a recent meeting of this Society the subject of the water-supply was discussed and the Society came out strongly in favor of filtration and of the public ownership of the filtration plants. It was stated that "the public safety demands the immediate enactment of such legislation as may be necessary to authorize the construction, maintenance and operation under public ownership and control of a proper filtration system," and that "the Society warmly appreciates the course of those members of select and common councils who have earnestly and untiringly worked for filtration under public ownership."

NEW INSANE WARDS FOR THE PHILADELPHIA HOSPITAL. — It will be remembered that a short time ago the JOURNAL mentioned the fact that the condition of the insane wards at the above hospital had reached the stage of overcrowding and more room should necessarily be provided. It is gratifying to state that an ordinance has recently been passed by the Council Committee appropriating \$60,000 for the erection of two wards for the insane at the Philadelphia Hospital.

EMERGENCY CORPS OF PHILADELPHIA WANT TO GO TO THE FRONT. — Dr. T. H. Andrews of the Emergency Corps of the Department of Public Safety recently tendered to the government the services of the entire corps, including the police surgeons and assistant medical inspectors. So far no word has been received from the proper officials regarding the acceptance of the offer, but all are eager to enlist.

Washington.

HEALTH OF THE DISTRICT. — The report of Health Officer Woodward for the week ended April 23 shows there were 105 deaths, of which 56 were white and 49 colored. The principal causes of death were, diseases of the lungs, 26, of which 18 were from consumption; nervous diseases, 19; circulatory, 9. There were 4 fatal cases of typhoid, 2 of diphtheria and 4 from la grippe. There were 35 cases of diphtheria and 47 of scarlet fever under treatment at the close of the week. Dr. Maurice E. Miller was appointed assistant medical sanitary inspector and Dr. Walter K. Brothly physician to the poor.

WASHINGTON OBSTETRICAL AND GYNECOLOGICAL SOCIETY. — The 280th meeting of the society was held on April 22 at the residence of Dr. H. L. E. Johnson. Dr. J. T. Kelly, Jr., read the essay of the evening, entitled "Vaginismus." A very interesting discussion followed, participated in by Drs. Sprig, S. S. Adams, Smith, J. T. Johnson, Acker, Bowen and H. L. E. Johnson.

MEDICAL SOCIETY. — The meeting of the Medical Society held on April 20, was conducted jointly with the Washington Anthropological Society, Dr. S. C. Busey, the president, presided. The general subject for discussion was the treatment and education of the deaf. Dr. Frank Baker discussed the anatomy and physiology of the ear; Dr. Reyburn, causes of

deafness; Dr. Lamb, the criminal and degenerate ear, and Dr. E. M. Gallaudet, the European methods of treating the deaf. At the meeting held on the 27th ult., Dr. Robert Fletcher read a paper entitled, "A Tragedy of the Great Plague of Milan, 1630;" Dr. Snyder, "Cerebellar Abscess Following Otitis Media; Case and Specimen;" Dr. Lamb, "Specimen of Anencephalic Fetus."

COMPLIMENTARY DINNER TO DR. SAMUEL C. BUSEY.—On April 16 fifty members of the Medical Society gave a complimentary dinner to Dr. Samuel C. Busey, their president, in honor of the fiftieth anniversary of his graduation as Doctor of Medicine. Dr. A. F. A. King was toastmaster. Dr. T. C. Smith responded in an eloquent speech to the toast, "Dr. Busey, President of the Medical Society." Surgeon-General George M. Sternberg, in his usual classic manner, responded to the toast, "Dr. Busey, Citizen and Sanitarian." Dr. George M. Kober, in a brilliant speech, responded to the toast, "Dr. Busey, Physician, Author and Teacher." Dr. Busey's response was the feature of the occasion and will be pleasantly remembered by all present.

CENTRAL DISPENSARY AND EMERGENCY HOSPITAL.—At the meeting of the board of directors, held on April 29, the following members were elected to serve as directors for three years, Drs. George B. Harrison, W. H. Hawkes, T. M. Murray, J. T. Johnson, Mrs. Arnold Hague, Mrs. Richard Mulligan, W. J. Boardman, John W. Foster, J. L. Bradley and George McLanahan.

Cincinnati.

THE REGULAR Monday meeting of the Academy of Medicine of April 25 was devoted to reports of cases with discussion. Dr. Louis Stricker exhibited a patient aged 23 years who had suffered from the discharge of a couple of sinuses behind the left ear, evidently coming from the mastoid process, for twenty years. When first seen she was semi-comatose with attending symptoms. An immediate operation was advised and she was put on the table that same day. The Stacke-Schwartz was the operation made, and the antrum, the attic, the middle ear and the operative wound were all thrown open into one large cavity, which was subsequently treated with dry dressings. As was expected on opening the mastoid, extensive necrosis was present and the diseased bone was removed for the most part with the spoon. Dr. Joseph Ransohoff reported a case of uterine fibroid, in which the tumor mass had involved one of the cornua and had extended into the broad ligament, causing some pressure symptoms and giving the impression to the examining finger of ovarian and tubal disease. The same member also reported the following: Girl, 4 years of age, was brought to the city with a history of a tumor of the right neck of several months' duration and very rapid growth. Three weeks ago the parents had noticed that the child's feet and eyelids were somewhat swollen every morning but that this swelling promptly disappeared during the day. The tumor had pushed the larynx far over to the left, it was nodular, and these symptoms combined with rapid growth and situation of the neoplasm, determined him in the diagnosis of lymphosarcoma. The examination of the urine showed in addition to a considerable amount of albumin, epithelial casts and numerous blood corpuscles. It was thought that the acute nephritis was dependent upon septic infection from the tumor and it was determined to remove the latter, which was easily done under chloroform anesthesia. The result was gratifying in every respect: the albumin, casts and corpuscles disappeared completely from the urine and the dropsical symptoms also disappeared. Microscopic examination of the tumor confirmed the clinical diagnosis of lymphosarcoma. Discussion was by Drs. Ricketts and Kramer. Dr. J. M. Withrow read a report of fifteen cases of abdominal section supplementary to the thirty-five reported last fall, making a total of fifty consecutive cases without mortality. Dr. W. E. Keily reported a case of walking

typhoid in a woman aged 60, who died of peritonitis following perforation of the bowel. The peculiar symptomatology led him at first to suspect acute dysentery, but this diagnosis was soon changed to appendicitis with rupture and an operation was advised, but was refused by the woman. The occurrence of five bloody stools rather invalidated the latter diagnosis and typhoid was next thought of. Postmortem showed the case as above stated. Discussion was by Drs. Cleveland, Ransohoff, Kramer (Widal reaction), Schenck (blood count), Oliver (perforating duodenal ulcer), Ricketts and Keily. After report of case of ophthalmia neonatorum by Dr. S. C. Ayres the meeting adjourned.

THE ANNUAL REPORT of the health department for 1897 is now being distributed among Cincinnati physicians. During the past year a laboratory has been fitted up in the city buildings where bacteriologic and pathologic examinations among the poor are made free of charge. For the most part these have been in diphtheria and tuberculosis patients. According to a law enacted by the department, cases of tuberculosis are being reported and more rigid measures than formerly taken to prevent the spread of the disease. The milk and water supply have also attracted the attention of the health officer and the lessening of the number of cases of typhoid and summer diseases of children is the best witness of the efforts made in this direction. The law passed by the legislature several years ago requiring midwives to report cases of ophthalmia neonatorum immediately, which had practically become a dead letter, is again in force, and many cases of purulent ophthalmia in infants have received early treatment with a consequent saving of sight. In regard to school inspection, which question has been agitated by the department for some time, very little progress has been made, the necessary expense involved being the obstacle. In order to improve the efficiency of the force, examinations are called from time to time, and records here obtained are used in bestowing promotions. Two large maps inserted in the report show that contrary to general opinion, diphtheria and tuberculosis are more prevalent and deadly along the river and Mill Creek than in the heart of the city where the population is much greater.

VITAL STATISTICS.—The number of deaths during the year amounted to 5565, of which 5127 were white and 438 colored. The death rate for the total inhabitants on an estimated population of 405,000, was 13.74 per thousand as against 5916 deaths in 1896, a death rate of 16.90 per thousand on an estimated population of 350,000. For the whites the death rate was 13.14 and for the colored 29.20 per thousand of population, estimating the blacks at 15,000. The principal causes of death were: Phthisis pulmonalis, 675; pneumonia, 511; heart disease, 310; bronchitis, 235; diphtheria, 102; typhoid, 101; deaths by accident, 207; suicide, 69; homicide, 10.

THE PUBLIC SERVICE.

Vision of Recruits.

WASHINGTON, D. C., April 20, 1898.

In reply to Dr. L. R. Culbertson of Zanesville, Ohio, the following letter was written. Its publication is requested by Dr. Culbertson.

I am directed by the Surgeon General to acknowledge the receipt of your inquiry of the 18th inst., and to reply as follows:

Applicants whose eyes exhibit refractive errors requiring glasses for their correction should not be accepted for the line of the Army. Slight visual defects which, in the opinion of the examining officer, will not disqualify for service in the line, may be waived; but the same should be noted on the form for the physical examination of the recruit.

Color blindness is not a cause of rejection, but it likewise should be noted on the form.

Applicants may, however, be enlisted in the *Hospital Corps* who are subject to refractive errors of vision; provided these errors are not excessive, may be corrected by glasses, and are not progressive or accompanied by ocular disease. Nor do such defects disqualify candidates for appointment in the Medical Department.

Conjunctivitis, or other disease of the eye, if a temporary ailment, and susceptible of speedy cure without injury to vision, does not disqualify, but it should be noted on the examination form.

Respectfully,
CHARLES SMART,
Deputy Surgeon-General, U. S. Army.

Physical Examination of the State Volunteers.

Arrangements have been made by the War Department for the examination of the Volunteer troops called out under the President's proclamation of April 23, 1898, as to their physical qualifications for the military service. Medical officers of the Army have been assigned to the various rendezvous for this duty as follows:

State.	Rendezvous.	Medical Officer.
Alabama	Mobile	Capt. Wm. E. Purviance, Ass't Surgeon.
Arkansas	Little Rock	Major Harry O. Perley, Surgeon.
California	San Francisco	Major Robert H. White, Surgeon.
Colorado	Denver	Lieut. Col. Alfred A. Woodhull, Deputy Surgeon General.
Connecticut	Niantic	Major Ezra Woodruff, Surgeon.
Delaware	Wilmington	Capt. M. C. Wyeth, Assistant Surgeon.
Florida	Tampa	Major Henry S. Kilbourne, Surgeon.
Georgia	Atlanta	Major Blair D. Taylor, Surgeon.
Idaho	Pendleton	Major Louis Brechemin, Surgeon.
Illinois	Springfield	Capt. H. P. Birmingham, Ass't Surgeon.
Indiana	Evansville	Capt. Wm. J. Wakeman, Ass't Surgeon.
Iowa	Des Moines	Capt. G. J. Newgardner, Ass't Surgeon.
Kansas	Fort Leavenworth	Major John M. Banister, Surgeon.
Kentucky	Lexington	Lieut. Col. William H. Gardner, Deputy Surgeon General.
Louisiana	New Orleans	Capt. C. E. Woodruff, Ass't Surgeon.
Maine	Portland	Capt. H. R. Stiles, Assistant Surgeon.
Maryland	Baltimore	Major Louis W. Crampton, Surgeon.
Massachusetts	Springfield	Capt. G. E. Bushnell, Ass't Surgeon.
Michigan	Detroit	Capt. Benj. Munday, Ass't Surgeon.
Minnesota	La Crosse	Major Philip F. Harvey, Surgeon.
Mississippi	Jackson	Capt. J. D. Glennan, Ass't Surgeon.
Missouri	St. Louis	Capt. C. B. Ewing, Ass't Surgeon.
Nebraska	Omaha	Major Egon A. Koerper, Surgeon.
New Hampshire	Concord	Major Charles B. Byrne, Surgeon.
New Jersey	Jersey City	Capt. W. C. Gorgas, Assistant Surgeon.
New York	Peekskill	Major Louis M. Maus, Surgeon.
North Carolina	Raleigh	Capt. F. A. Winter, Assistant Surgeon.
Ohio	Columbus	Major Valery Havard, Surgeon.
Oregon	Portland	Capt. Edward R. Morris, Ass't Surgeon.
Pennsylvania	Mt. Gretna	Major J. D. Hall, Surgeon.
Rhode Island	Providence	Major C. L. Heizmann, Surgeon.
South Carolina	Charleston	1st Lieut. W. F. Lewis, Ass't Surgeon.
Tennessee	Nashville	Major W. F. Carter, Surgeon.
Texas	Austin	Capt. E. A. Mearns, Assistant Surgeon.
Utah	Ogden	
Vermont	Burlington	Capt. J. R. Kean, Assistant Surgeon.
Virginia	Richmond	Major G. W. Adair, Surgeon.
Washington	Tacoma	Capt. J. L. Phillips, Ass't Surgeon.
West Virginia	Martinsburg	Capt. B. L. Ten Eyck, Ass't Surgeon.
Wisconsin	Milwaukee	Lieut. Col. Henry R. Tilton, Deputy Surgeon General.
Wyoming	Cheyenne	Major Curtis E. Munn, Surgeon.
Dist. Columbia	Washington	Col. W. H. Forwood, Assistant Surgeon General.

Army Changes. Official List of Changes in the Stations and duties of officers serving in the Medical Department, U. S. Army, from April 23 to 29, 1898.

Major William C. Shannon, Surgeon, having been found by an Army retiring board incapacitated for active service by reason of disability incident to the service, his retirement from active service this date, by the President, is announced. April 23, 1898.

First Lieut. Benjamin Brooke, Asst. Surgeon, is retired from active service as a Captain, upon the finding of an examining board that he is disqualified for the duties of Asst. Surgeon with the rank of Captain, by reason of disability incident to the service, to date from April 20, 1898.

Capt. Leonard Wood, Asst. Surgeon, is relieved from duty in this city, Washington, D. C., and will proceed to the following named places, in the order designated, for duty in connection with the recruitment of a regiment of mounted riflemen, to be organized under section 7 of the Act of Congress approved April 23, 1898: Guthrie, Oklahoma Ter.; Santa Fe, N. M.; Phoenix, Ariz. Ter.; Carson City, Nev.; Salt Lake City, Utah; Cheyenne, Wyo.; Boise City, Idaho.

CHANGE OF ADDRESS.

Anderson, H. G., from 6658 State to 128 W. 67th st., Chicago, Ill.
Bennett, A. L., from Gross Butanga, Kameruns, to Gaboon, Libreville, West Africa.

Carr, B. M., from Chicago, Ill., to Cedar Springs, Mich.; Capron, V. J., from Kau, Hawaii, to Everett, Wash.; Curtis, A. M., from Chicago, Ill., to Freedman Hosp., Washington, D. C.; Corbel, R. L., from Richmond to Chucksuck, Va.; Caton, G. A., from Richmond, Va. to Grantsboro, N. C.; Couch, E. E., from Milwaukee to Glenbenlah, Wis.

Dillon, I. H., from Chicago, Ill. to Auburn, Neb.; Dickinson, J. W., from St. Louis, Mo. to Keswick, Ia.
Earl, R. W., from Milwaukee to Columbus, Wis.

Fuson, A. U., from Chicago, Ill. to La Pay, Ind.; Feehey, F. S., from Chicago, Ill. to Rochester, Minn.

Hartman, Jr., J. C., from Pittsburg to Keown, Pa.; Hawley, E. A., from Chicago, Ill. to Greenville, Tex.; Harrison, A. C., from Meyersdale, Pa. to Tallersville, Kent co., Va.; Holmes, E. L., from 206 Cass St. to 558 E. Division, Chicago, Ill.; Hooper, E. W., from Des Moines, Iowa, to La Harpe, Kans.; Homer, H. C., from Chicago, Ill. to Crain Creek, Ia.; Hull, J. F., from Iowa City to Badger, Ia.

Korn, A., from 741 S. Halsted St. to 8269 Cottage Grove Ave., Chicago; Kinneman, J. G., from Mexico to Goodland, Ind.; Kilgore, F., from Yorktown to Parker, Ind.; Kline, J. H., from Bandon, Ore. to Fortuna, Calif.

Lucas, F. B., from Chicago to Peoria, Ill.
Miller, De Laskie, from 56 to 110 Astor St., Chicago, Ill.; Mosher, B. D., from Sandwich to Prairie Center, Ill.; Meek, J. H., from Glencoe to Smithfield, Ohio; McDougall, G. T., from Milwaukee to Osseo, Wis.

Oshrofferson, A. L., from St. Louis, Mo. to Lind Center, Wis.

Page, T. H., from Chicago to Jerseyville, Ill.; Potts, J. M., from Wilmington to Massillon, Ohio; Pilleher, J. E., from Fort Crook, Neb. to Carle, Pa.; Patch, Wm., from Ellsworth to Stamford, Ill.; Perkins, E. L., from Indianapolis to Owensburg, Ind.

Rumbold, T. F., from Union Trust Bldg. to Century Bldg., St. Louis, Mo.; Rawley, W. S., from 6325 Monroe Ave. to 68 and Wallace, Chicago,

Ill.; Roby, Palmer Mrs., from Cleveland, Ohio, to New Castle, Pa.; Runkel, W. W., from Jefferson to Cambria, Wis.

Small, A. R., from 3131 to 3035 Indiana Ave., Chicago, Ill.; Snyder, L. A., from Columbus, Ohio, to 246 W. Adams St., Chicago, Ill.; Shastid, T. H., from Galesburg, Ill. to 175 Mauchester St., Battle Creek, Mich.

Terrell, H. W., from Greenville to La Grange, Ga.; Turner, J. A., from Indianapolis to Martinsville, Ind.; Trueblood, Chas., from 302 E. New York St. to City Hospital, Indianapolis, Ind.

Visser, J., from Chicago, Ill. to Ogema, Wis.

Whiting, E. D., from Chicago to Aurora, Ill.; Walker, J. W., from 305 Park Ave. to 1629 West Adams, Chicago, Ill.; Witter, G. F., from Grand Rapids, Wis. to San Jose, Calif.; Waddell, G. from St. Louis, Mo. to Essex, Mo.

Yoder, J. A., from Cleveland to Millersburg, Ohio.

THE CLIMATE OF COLORADO FOR RESPIRATORY DISEASES.

BY CHARLES DENISON, A.M., M.D.

Emeritus Professor of Diseases of the Chest and of Climatology,
University of Denver; Ex-President of the American
Climatological Association, etc.
DENVER, COLO.

(Concluded from page 1073.)

PART II:—SENSIBLE TEMPERATURE AND THE EXPERI- ENCE OF INVALIDS, WITH CONTRAINDICATIONS FOR THE HIGH ALTITUDE CLIMATE.

Variability versus equability.—The study of temperature ranges assumes importance from the undue weight given by the medical profession and the laity to supposed injurious effects of thermal changes. Let us investigate and see if it is the dampness and not the thermal oscillation which is responsible for the injury. How uniformly variability goes with dryness and equability with moisture may be illustrated by the daily and monthly ranges of temperature at places which represent dry and moist climates. Chosen without reference to this particular evidence, twenty-five *dry* and twenty-five *moist* prominent signal stations and health resorts in the United States give the following remarkable average excesses of mean daily temperature ranges. The excess of the driest one-fourth over the moistest one-fourth of them is 22.9 degrees, and the same average excess for the monthly ranges of temperature is 2.1 degrees greater variation in the dry than in the moist localities.

Again, taking the fifteen *most* and the fifteen *least variable* signal stations in the United States (out of 136 stations) for the year, we have an average excess of temperature variability of the most over the least changeable stations for spring, 18.5; summer, 16.2; autumn, 17.6; winter, 16.5, and for the year, 16.8 degrees F. The first fifteen are *extremely dry* with daily average for the year of 28.7, and the second fifteen *decidedly moist* localities with a daily average variability of only 11.9 degrees F. This evidence is conclusive that variability goes with dryness.

Seasonal ranges of temperature likewise show the inseparability of equability from atmospheric moisture, and of variability from dryness. Compare the winter and summer temperature lines on seasonal charts. The sea is the great equalizing influence, and the colder land in winter turns these isotherms to the south for a considerable distance in the United States, viz., on the western boundary, about parallel with the coast. In the summer, however, when they leave the ocean, these lines are turned nearly as much to the north as the winter ones are to the south. The farther we get away from the humid influences the greater is the variability of temperature. It is not maintained that extreme variability should always be

sought or that of two places, with all other advantages the same, the more variable one is the better. On the contrary, the less variable would certainly be preferred in cold weather. It is maintained, however, that variability is quite a uniform constituent of dry high places and that as the dryness predominates the marked variability is less felt and is less, if at all, objectionable. On the other hand, marked atmospheric equability, wherever found, is *prima facie* evidence of excessive humidity.

The worst that can be said against combining variability with the favorable attributes of climate for consumption is that its defence is necessary in order to overcome a prevailing prejudice and to show that this variability is a *sine qua non* of the preferable combination. But there would be no excuse for advocating a false theory of climate, even if this one element were unfavorable. There is a prevalent exaggeration of the effect of temperature changes. The change gets the blame which rightly belongs to the element of humidity, which constituent is always excessive when a given change is injurious. For instance, a change of 20 degrees from a warmer to a colder temperature, with the relative humidity 50 per cent. does not equal in the sensation or shock to the system a change of 8 degrees with the relative humidity at 80 per cent. The former change does not produce saturation, but the latter does; so does a change of 5 degrees with the humidity at 90 per cent., and even 2 degrees with the humidity a 95 per cent. of saturation (see Glashier's table). Therefore it is the humidity of the air which, through conduction of heat from the body, makes a slight temperature change, with the air near saturation, equivalent to a much greater change with the air dry. It is one of the mistakes of medical antiquity for equability to be insisted on as a constituent of the best climate for consumptives, yet this seems to be a fallacy most difficult to correct. It is essential to insist upon equability for humid climates, but for dry, cool, elevated resorts it is out of the question. There is something wrong with the reasoning powers of an author who jumbles together climatic attributes so that his "ideal climate" has no real counterpart among the known climates of the world. The trouble is chiefly with the vague use of the words equability and variability. Until now there has been no accepted line of definition between these two terms. This we should have. If the mean of variability for the whole country were taken as a just division, and the daily and monthly ranges of temperature were the criterion to decide by, we would then have a division line approximately represented by 18 to 20 degrees F. for the daily, and 46 to 48 for the monthly range, the same being in harmony with the dividing line between moisture and dryness on the writer's climatic charts. This is a fair line of division which is commended for general adoption, especially by those authors who write about equability as essential to pulmonary resorts.

Actual versus sensible temperature.—Captain W. A. Glassford, signal officer United States Army, Denver, Colo., has given much attention to comparing the actual with the apparent climate in Colorado. Omitting interesting but lengthy illustrations, he says: "Taking the city of Denver, we find that during the year there are 172 days on which the daily mean temperature is above 50 degrees F. and 64 days below 32. The 50-degree point is the lowest mean temperature which mankind considers comfortable, and it is the critical point as regards the growth and development of the most important staple crops. The same number of comfortable days prevail during the year at Albany, N. Y., as here, but instead of 64 they have 107 days with temperature below 32 degrees (freezing).

"Let us now turn to a few facts as to Colorado summers. Denver is on the line of 105 degrees extreme maximum temperature, that being the highest ever observed here. To the west of this line these extremes diminish and to the east they increase.

"I wish, here, to draw particular attention to the unfairness—unintentional to be sure—to which Colorado and the entire West is subjected in the official consideration and publication of its record of heat as affecting animal life, in that there is overlooked the important element of dryness, which moderates the sensible effect of the extremes of heat as well as of cold. There are in all temperature records two elements—the sensible temperature or that which expresses the heat or cold felt by the human beings, and the apparent temperature, a mere record of how the mechanical thermometer is affected. It is the apparent that receives publication, greatly to the undue advantage of the East and the detriment of the West.

"Strange as it has always appeared to me, the people of the West have always allowed this thermal element of climate to rest upon a common standard for the East and West, where the resultant effects are so dissimilar, in that the important factor of dryness of the air is entirely overlooked. The West should insist upon the publication of the sensible temperature, that is, what is technically known as the reading of the wet bulb. We would understand then why the high thermal conditions, apparently the same, do not here cause the cessation of business, prostration or death to man or beast, as among our Eastern neighbors. The difference between the apparent and the sensible heat in this vicinity being many degrees, explains our extreme comfort, while summer prostration in the East is explained by their slight range of difference. The very highest official record of heat at Yuma, Ariz., is 118 degrees, but the sensible heat at the time—that in the reading of the wet bulb—was 32 lower or 86 degrees. In the Eastern States 86 degrees of sensible heat is not uncommon when the thermometer stands in the nineties."

Besides the quality of stimulation which is associated with variability, there is an important consideration in the purifying of the atmosphere which variability indicates. This happens through the alternate expansion of the air by heat and its contraction by cold together with the nightly chilling and sometimes freezing, which regularly render it inimical to germ life. The purity of the atmosphere which is represented by warm, moist and equable climates, is not to be compared with that purity which is represented by the opposite attributes. The first is where the temperature keeps within the limits of the

microbe's needs, where sound as well as heat is smothered within a short distance and the sun's rays give a dusky red glow. The second, indicating a comparative absence of germs, is where exposed meat can cure and not spoil, where distant objects appear near and where the unobstructed rays of the sun give nearly as white a light as an electric lamp does.

Diathermancy preferred to dense, moist or smoky atmosphere.—This diathermancy is the clearness or transparency of the air, which is a decided indication of its purity. It is with the atmosphere as with water. The larger the lake, with perfectly clear water through which one can see to a great depth, the better is the evidence of purity. So a large area, having throughout a similar atmosphere, through which one can see to most remarkable distances, must indicate as its coldness, rarefaction and dryness do, that the purity is approaching the absolute. This increasing purity of atmosphere, the absence of dust, smoke or moisture with its attendant infusoria is a decided feature of elevation, because with each rise of 1000 feet an equivalent stratum of air has been left below and, according to Professor Tyndall, each higher successive stratum contains less and less of infusoria. Professor Miquel of the Observatoire de Montsouris, near Paris, has achieved a result in the analysis of the air which is very interesting in this connection.¹

Miquel found the following numbers of bacteria in ten cubic meters of air taken as nearly as possible at the same time at the respective places: At an elevation from 2000 to 4000 meters, none; on the Lake of Thun (560 meters), 8; near the Hotel Bellevue, Thun, 85; in a room of the Hotel Bellevue, Thun, 600; in the Park of Montsouris (near Paris), 7600; in Paris itself (Rue de Rivoli), 55,000. These figures are certainly suggestive of the fact that atmospheric purity keeps pace with diathermancy. A rule for the average change in diathermancy, for each rise in elevation, was devised by the writer in 1876 from consecutive observations of the sun temperature at 2 p.m. and at different elevations²: *For each rise of about 235 feet there is one degree greater difference in temperature between sun and shade at 2 p.m., as shown by metallic thermometers.*

The distribution of atmospheric moisture closely coincides with that of the soils. The dry soils, the rocky and sandy portions of mountainous configuration, and the dry sandy loams, with rapid absorption of air vapor and radiation of heat, nearly represent the dry climates. *Per contra*, the clay soils and marshes of level sections, with their moist cold and the easy solution of organic substances, are closely associated with the moistest atmospheres, excepting where humid currents come from over large bodies of water. This correspondence with reference to broad areas becomes strong proof of the utility of our preferable combination of climatic attributes.

A mountainous country, aside from the benefit of elevation, has many advantages over a level region. Chief among these are the quick drainage, which allows of no detention of stagnant water, the greater surface of the earth exposed to absorb atmospheric moisture, the many faces of rocks, etc., favoring radiation of heat and reflection of light, the element of stimulation, both atmospheric and electric, the controlling of severe winds, the variations of scenery, temperature and exposure afforded and the facility

¹ "Chronic Pulmonary Phthisis," by Hermann Weber.

² Rocky Mountain Health Resorts.

with which one can indulge in climbing hills and in pleasurable out-door activities. When these advantages are compared with the moisture-retaining properties, the sameness, the "siroccos," the trade winds, and the "northers" of level regions, one easily chooses between them.

The changes in the atmosphere accompanying the variability of temperature of mountainous places are decidedly electric. There is an increase of electric tension and there is an easier and more frequent interchange between the positive electricity of the dry air and the negative quality of the ground and clouds. The condition is very stimulating. This quality in high altitudes is associated with light showers, especially in summer time when they are most needed to clear the atmosphere. The simultaneous whirl of a light wind, often seen at a great altitude, purifies by its substitution of an unused and fresh supply of air for that which may be impure. Where people crowd together in large numbers, the daily freezing of the air is the only sufficient substitute for a mild wind. We thus arrive at the conclusion that in densely settled sections continuous stillness of the atmosphere is only to be preferred in the freezing weather of winter. The warmer the atmosphere the more air movement is desirable.

It is where there is a total absence of land influence, as at sea and on islands far out, or on dry, sandy coasts, with favorable sea winds prevailing, that low altitudes may best be substituted for high ones. The malarial and organic emanations from the soil, which are a fruitful source of increased mortality from consumption (Buchanan and Bowditch), are thus excluded from the climatic calculation. The aseptic condition of the atmosphere out at sea (Miquel), its quality of stimulation, and the tonic effect of the change, including the improvement of appetite and digestion, are all akin to the best effects of high altitudes, though the elimination of septic germs is less perfectly performed.

The evidence of experience.—This is in harmony with these favorable climatic attributes. One difficulty is our inability to make use of statistics of low lands which are fair for comparison with those which have been tabulated for high altitude stations. We have to explain in this connection, that the term "cured" should be qualified as meaning a more or less permanent arrest of disease, and that the records given, embrace only those treated during a limited period by any of the observers.

The tabulated records at hand of careful and trustworthy physicians, show the favorable results in both the Swiss Alps and in Colorado (4500 feet and upward) to be as follows: For all stages of the disease, of 247 consumptives treated in the Swiss Alps, 38 per cent. were "cured" among 72 per cent. benefited. In Colorado 162 cases, 35 per cent. are recorded as "cured" among 75 per cent. benefited. This slight difference in percentage should be explained as quite natural considering the variable times of treatment, and the diverse interpretations by different physicians of the extent of the disease and of the relief afforded. Colorado really has many advantages over Switzerland as an all the year round resort, and also in the facility afforded to graduate the altitude to the season of the year.

In conclusion it is apparent that the element of altitude is inseparable from the best climate for

chronic pulmonary diseases. The natural question then follows: What is the limit up to which this combination of qualities can be carried that the best results may be obtained? This is a question of individual adaptability which has to be settled by the attending or consulting physician. The best method of settlement is to determine what conditions or diseases are suitable for the extreme or the preferable combination of attributes, and then arrive at modifications or rejections of the high climate cure by a system of exclusion. This method is that always advised by the writer (Rocky Mountain Health Resorts), and is seconded by the extended experience of Jaccoud as given in his work on "The Treatment of Phthisis." Jaccoud's conclusions are in the main correct, but it must be borne in mind that they, like those of Tucker Wise, Hermann Weber, and most of C. Theodore William's records, pertain to a more northern latitude than we reason about in the United States. In the Engadine, in Switzerland, the limit of timber growth is at or below 8000 feet, an elevation compared with a similar limit at or above 11,000 feet in Colorado. Here the gradual rise, the distance from the sea, and the peculiar protection of mountain ranges make the change from low levels less severe. Also, in America, we have an increased advantage over most of European high climates in that we keep up the curative effect by suitable increase of altitude in summer. Instead, they are compelled, as at Davos, St. Moritz, etc., to give up the chosen climate treatment during the warm weather. The plan of deciding if the preferable climate can be made use of in a given case by exclusion because of negative conditions will not be readily accepted by the over-zealous advocates of low climates. This is, perhaps, because generally speaking, the more reasons there are for exclusion from the better high climate, the less likelihood is there for an ultimate recovery. Besides, it is not always easy to decide what change of climate a given patient can have, because of the varying conditions to be weighed, both as to the patient and as to the climate. We have to summarize by saying that the preferable climate for the great majority of consumptives in the United States varies, according to the case, between over 2000 feet elevation in the north in winter, and 10,000 feet as a possible extreme in the southern portion in summer. As to patients, not omitting social and economic bearings, they vary also, all the way from those cases that are hopeless to those that are to prove curable. There must then, of necessity, be many very delicate and intricate questions to be decided by the attending or consulting physician. Of course, then, any rule of procedure must be susceptible of much variation. The physician who takes the most factors into account and weighs them best will be most successful in the management of each individual case. With this broad proviso we will state some general reasons why a given invalid may *not* go to an otherwise preferable high climate, and thus emphasize those who *may*. Assuming that he can relinquish home and business cares and is financially able to remain from four months to two years away from home, or better, perhaps, make a permanent residence where he recovers, then the following are what we may consider as possible contraindications to a climate above 5000 feet elevation, such as that along the eastern base of the Rocky Mountains from Wyoming through Colorado into New Mexico and northern Arizona.

POSSIBLE CONTRAINDICATIONS.

1. The coldest season of the year, intensifying the effect of altitude too much for very delicate and sensitive persons, coming from much warmer climates.

2. Advanced age of the individual, rendering acclimatization difficult; "senile phthisis" and the fact that the patients are too old and feeble to exercise out of doors.

3. A very excitable nervous temperament, aggravating the stimulation of the high climate, producing irritability, and possibly wakefulness in a few extreme cases.

4. The state of some women, because of a greater susceptibility and lesser adaptability to the change and to out-door life than men have.

5. Valvular heart lesions, with rapid action of the heart, especially with the previous exceptions. Diseases of the great vessels, such as aneurysm.

6. Marked and extensive emphysema, pneumothorax, and hydro-pneumothorax.

7. Active pneumonia and existing hemoptysis. If the pneumonia or the hemorrhage is recent, the contraindication amounts to little; if remote, such cases are usually favorable. If there is reason for doubt in any such hemorrhagic or inflammatory case, a gradual rise in elevation should be advised.

8. Very high body temperature, whether it is rather constant, as in some inflammatory states or in catarrhal extensions beyond a tubercular center in the lung, or whether it is regularly vacillating, *i. e.*, daily subnormal in the morning, and regularly up to 103 degrees or more later in the day, especially in so-called catarrhal phthisis and in laryngeal tuberculosis (unfavorable cases anywhere).

9. Too extensive involvement of lung tissue in diseased action, *i. e.*, so that the healthy spirometric record is more than one-half abridged.

"Phthisis with double cavities, with or without pyrexia; cases of phthisis when the pulmonary area at low levels hardly suffices for respiratory purposes" (C. T. Williams).

10. The active stage of lung softening, if accompanied by daily fever, or in one of a decided hemorrhagic diathesis. "Quick consumption" with or without intestinal ulceration or albuminuria (without prejudicing such a case if the acute symptoms are abated).

A proper estimate and consideration of these ten possible modifiers of the high altitude prescription tend to give the physician confidence of success in sending to well chosen elevated regions, such as the plains and foothills about Denver, incipient and first-stage tubercular pulmonary invalids, particularly if they are hemorrhagic or inflammatory cases without high fever, persons not too old and of fair resisting powers, and those with advanced or third-stage disease with a unilateral cavity already well protected by a conservative fibrosis.

The time to remain in a climate in which recovery seems to have taken place is a more delicate question than is generally considered. This is because tuberculosis is apt to be rendered latent by the climatic treatment and by nature's healing plan—the fibroid or hardening process. It is often essential not only that a patient should reside permanently in the new immunity climate he has reached, but that he should adopt a new and outdoor active occupation, in order to obtain the best results. In less urgent cases, encouraged by the absence of all physical signs of dis-

ease during a year or more, by gain in weight and by normal spirometer and manometer records, patients may return to their former homes to live with comparative safety. Many, however, find themselves deceived as to their real condition when they return to their old haunts and confined occupations.

The three principal agencies of relief or cure of tuberculosis thus far discovered, independent of a possible specific (some modification of tuberculin) to produce immunity, are diet, exercise and climate. These, rightly employed, tend to render the disease latent or innocuous through the process of fibroid healing in the lung tissue. The body resistance is strengthened, but the tuberculosis being latent, the individual has the same fight to go over again (it may be with a more unfavorable outlook) if he does not accept and act upon the lesson of experience. His climate, occupation and his habits of life, as to exercise and feeding, must thereafter coincide with what he has found to be most beneficial in his health-seeking journeyings.

Asthma and hay fever.—The name "hay fever" is a misnomer as applied to the breathing disability of many people, since the growth of hay has to do with only a small proportion of these cases. The causes are various, and whether having to do with the flowering of apple blossoms, the pollen of corn or of the Roman wormwood, nervous shock or to the dustiness of "dog-days," the fact remains that four-fifths of these so-called "hay fever" subjects are prone to cough and asthma. The nature of the affection is, like asthma, of nervous origin, and the best mode of relief in many cases is, much like that of asthma, to get out of the region of excessive vegetation into the rarefied air of the mountains.

One of the most troublesome complications in some of these "hay fever" cases is the asthma. The author gives it as his opinion, based upon an extended experience in Colorado, that there is no cure for pure and simple asthma equal to a resort to a well chosen high altitude such as the cool, dry and sunny inland plains and lower mountains of Colorado.

There is a prevalent misconception about this question of asthma, which explains the non-recognition of the above truth, by many sufferers or by their medical advisers. It is not well enough understood what emphysema is, that it is not asthma, but rather the result of it. Asthma is a nervous disease. It produces the undue spasm or contraction of the circular muscular fibers of the smaller bronchial tubes, and the consequent hindrance to the air-circulation, or free inspiration. On the contrary, emphysema is a mechanical state of the vesicular portions of the lungs which complicates such conditions as asthma, whooping-cough, bronchiectasis (dilated tubes) and bronchitis, until there exists a more or less permanent disability of the air-cells, leading to their over-distension and the loss of their natural elasticity. Hence the difficulty and incompleteness of expiration. The one condition—asthma—hindering inspiration, is helped and sometimes immediately relieved by elevation; while the other—emphysema—hindering expiration, is sometimes made worse by the same element of air rarefaction. This is because the affected air-cells and distended bronchial tubes in emphysema are still more crowded with air, especially under any physical exertion, by the necessity to breathe more air in the mountains, in order to get the required amount of oxygen. Therefore, those of the "hay fever" class who have, or are prone to asthma, might be expected to

find much relief, or a cure for the time being, in the high altitudes of the interior of Colorado. Pure and simple asthma usually meets at Denver, or in the hills to the west, with an elevation, aided by the sparsity of vegetable growths and the pollen-producing plants, which prevents the spasmodic contraction of the bronchial tubes, and the cure for the time of sojourn is established.

Malaria.—The aid of the high climate in eliminating malarial poison from the system of a person so charged, is a subject worthy of notice. The suspicion that malaria, like la grippe, bears a near relation to tuberculosis is firmly fixed in the minds of some physicians. So the opposite climatic conditions to those which produce the malarial complications are the more trusted to wear out these evils. It is rather a confirmation of this eliminating process that the chills, when one comes up here with them, are sometimes aggravated at first. The general result, however, is good. The elimination of the malarial poison, which many sojourners in Colorado from Texas and the Mississippi Valley have shown by their happy experiences does take place, constitutes the removal of one of the most fruitful sources of pulmonary consumption. Thus the fascination is explained which the high altitude climate has for many people, who have left behind them the "epidemic shades" of these low sections.

In sending invalids to Colorado, a correct diagnosis is an essential condition of success; for, the physician of much experience in high altitude resorts has to acknowledge that too many failures or limited recoveries can be accounted for by a previous neglect to duly estimate a lung disease as farther advanced than it had been announced, or by a failure to sufficiently recognize the damaging association of "mixed infections," such, for instance, as arise from other blood taints than tuberculosis, or from the non-recognition of the co-existent or causative effect of fermenting blood states, due perhaps to dyspepsia, or to the non-elimination of effete material, as in amenorrhea, with or without constipation.

Allowing patients to go to high altitudes as a *dernier ressort*, who have not a 5 per cent. chance of living six months anywhere, is strongly deprecated. It should be remembered that every rule has its exceptions, and the stated contraindications named may perhaps be neutralized by favorable circumstances, such as the best time of year for the change, previous experience of the individual in high climates or the combination of compensating conditions in the same patient.

The seasons.—These natural divisions of climate necessarily influence the journeyings of invalids, the time of going as well as the choice of the destination. The lack of space here to introduce them, and the advantage of the medical advisers to have on hand an ever ready reference to all important seasonal weather records, leads the writer to refer for all these data to his seasonal humidity, temperature, rain, wind and cloudiness charts.

The question of the season of the year is one of no small importance, notwithstanding the general truth that the best time for a person to go is when he has to, because of the beginning of lung trouble and not as a last chance. For one who really needs the change, there is no better time than the present. The season of the year does not produce so much difference in the indications for a given invalid's hastening away as

does the advance of the disease from incipency, or the first stage, to the ominous second stage, when the lung is "going to pieces." While the summer is by far the most satisfactory season to be in our mountains, and the autumn is a good season to get acclimated to a given high altitude before cold weather comes on, yet many maintain that the best results obtained by those suited to the rarefied air cure, are secured in the winter season. On the other hand, others not so well suited, such as neurotic persons, those unable to exercise outdoors because of advance of disease or extensive fibrosis leading to marked dyspnoea, or those with too sensitive mucous membranes to stand the cold, stimulating and dry out-of-door air, may do well to modify the effects by going first, via Texas perhaps, to southern New Mexico, Arizona or California, during the months from November to March, intending to reach Colorado afterward.

To this conclusion then we have arrived, namely, that for the great majority of cases of consumption this adaptation will be most fully secured in the dry, cool, rarefied, sunny, clear and pure, though variable, atmosphere of a well chosen high altitude, such as is fittingly represented by the region along the eastern base of the Rocky Mountains.

THE ADMINISTRATION OF ANESTHETICS.

BY DAVID H. GALLOWAY, Ph.G., M.D.

CHICAGO, ILL.

A man who desires to study medicine can find many places in Chicago where they will undertake to teach him, but I do not know of any place where they will teach him to administer anesthetics. There are many places where he may learn but no place where any provision is made for properly teaching the subject.

The student is not left to his own resources in the treatment of cases which come to the dispensary, but such treatment is always under the supervision of a teacher. The administration of anesthetics, however, is one thing which he is called upon to do practically without any instruction. This is one of the most difficult tasks to satisfactorily accomplish, one where skill, experience and personal judgment are required in the very highest degree and where rules are so obscured by exceptions as to be nearly useless. Yet such is the inertia of college management that after fifty years use of anesthetics, medical faculties are not yet awake to the necessity for adequate instruction in this very important branch of the medical art.

Many of the diseases which the student sees in the clinics will never be seen by him, as a general practitioner, in after life; many operations watched, he will never be called upon to perform, but no student or practitioner will escape being sometimes called upon to administer an anesthetic. Every case of disease brought before the classes in the medical colleges is utilized to the utmost as material for imparting instruction, except the numerous anesthetics. In these cases all the attention of students and teachers is concentrated on the operation, though it may be nothing more than opening a boil.

One reason for this apathy may be the fact that nothing can be learned about the administration of anesthetics from a distance even so great as the front row of seats in the amphitheater and, as but few per-

sons could get near enough to the patient to observe the phenomena of anesthesia, this source of instruction is wholly neglected.

A student will learn more in administering one anesthetic under the eye and direction of a competent instructor than by the administration of twenty, if left to his own resources. At present every student must get his skill by the hardest kind of experience and at an entirely unknown expense to his patients. He is called into the amphitheater and told to anesthetize a patient; he either gets no instruction at all or only that which some other student, who may have anesthetized two or three patients, is able to give him. He knows only what he has been able to learn from his seat in the amphitheater and that is little more than the fact that the patient's face is covered and the anesthetic poured on till he no longer moves. That this is playing at odds with death may perhaps be appreciated when it is realized that many times during the maintenance of anesthesia, safety or great danger, even death, depends on whether the anesthetist's judgment prompts him to give a little more air or a little more anesthetic.

These conditions will justify our writing on this subject with especial reference to the needs of the student who wishes to be able to give an anesthetic skilfully with safety to the patient and satisfaction to the surgeon. The student in this case includes not only the man in and just out of college, but also the practitioner who does not consider himself proficient in producing and maintaining general anesthesia.

The college clinic is the legitimate place for acquiring this experience and if properly conducted would turn out skilled anesthetists. The dispensary or clinic patient is entitled to the same consideration and treatment as is accorded those in private practice. In either case the anesthetist should try to make the acquaintance of the patient some time before the hour set for the operation and gain his confidence so far as possible. If he can control the patient, a few days preparation is a great advantage. In that case, examine the urine carefully for evidences of nephritis and ascertain whether the excretion of solids and urea is normal. Give the alimentary canal a thorough cleaning, and a few hours before the operation, the lower bowel a flushing. The patient should abstain from food for twelve hours before the operation, if this time includes a night's sleep; half that much daytime is enough; he should take no water within two hours of the operation. If the operation be done before noon the patient should have no breakfast, but about two hours before the time set should be encouraged to drink two or three glasses of water, preferably hot; this and the flushing of the bowel will usually prevent that dreadful thirst which follows anesthesia, the gratification of which causes such violent vomiting, which wears out the patient and affects adversely the result of the operation. For this reason castor oil is a better cathartic than the salines, as it does not abstract so much water from the system and is therefore less likely to produce thirst.

The heart and lungs should be examined carefully; in fact, the general condition of all the organs of the body should be known as far as possible.

It usually happens however, that the anesthetist does not see the patient until the hour set for the operation (in which case he must trust that the surgeon has seen to all these preliminaries) and he is frequently told "the patient is in that room, go in

and get her to sleep as quick as you can." This I would not do. Insist that either the family physician or the surgeon take you into the room and introduce you to the patient. In doing this, he should assure the patient of your skill and of her safety in your hands. The anesthetist should then spend a few minutes talking to the patient and examining her heart. This should be done for the purpose of impressing the patient with your carefulness, even though you know that examination has already been made by a competent person. Assure yourself that there are no foreign bodies in her mouth; rub a little petrolatum on her lips, nose and cheeks so as to lessen the danger of blistering the skin with the anesthetic; place the mask over the patient's face and tell her to close her eyes as the anesthetic is irritating to them. Tell her to breathe regularly and rather deeply and to count after you; explain that sensations of suffocation are felt by most patients; that they have no adverse significance and will pass away after a few deep inhalations. In giving chloroform, tell her that every time she counts you will pour on a drop of chloroform. If the patient is very nervous, continue the counting a few minutes without giving any anesthetic. It is wonderful how this will, in many cases, bring down the pulse and steady the breathing. Then begin the chloroform, drop by drop, very slowly at first and more rapidly as the patient's voice indicates that unconsciousness is approaching. In this way patients are often put to sleep without experiencing any unpleasant sensations whatever, and seldom will there be any sign of the stage of excitement. After anesthesia is begun, the patient should not be moved any more than is absolutely necessary. If the patient is a man (or a woman who is not nervous) it is better to put him on the operating table before beginning with the anesthetic. The room should be quiet, no talking being allowed except that between the anesthetist and the patient; they should not be alone, however, unless some one is within immediate call to render assistance should any be necessary. A quiet room and an unexcited patient are the best possible conditions for the safe and easy induction of anesthesia.

From the beginning to the end of the operation the anesthetist must devote his entire attention to the condition of the patient and the conditions which conduce to the safety and the success of the operation. He must not watch the operation, though he must know in a general way how it is progressing, so that he may be prepared for any emergency. He must control the temperature and ventilation of the room, being less actively engaged than the surgeon he is better able to judge of the effect of these conditions on the patient. He must remember that the anesthetic is a drug, the administration of which very materially lowers the temperature of the patient, and he must insist that all parts of the body, which are not necessarily exposed, be thoroughly protected from cooling, by proper covering and hot water bottles when necessary. He must direct that the bed be properly warmed and prepared for the reception of the patient at the close of the operation, and must remove or superintend the removal of the patient to the bed. He must remain by the bed until the patient revives, and then give careful directions regarding care till recovery from the anesthetic is complete. The patient should be without a pillow for an hour or so, or until well recovered, though she should not

be allowed to lie with head hanging back in an uncomfortable position. If the patient is very weak or there has been much shock, the foot of the bed may be elevated.

Do not make a practice of giving drugs before or during every anesthesia. Occasionally, surgeons insist on giving a hypodermic of strychnia before beginning the operation, thinking that this helps to keep up the circulation and lessen shock. I have some times thought a hypodermic of morphin half an hour before beginning with the anesthetic, facilitated the production of anesthesia.

Resisting patient.—The greatest care is necessary in anesthetizing persons who actively resist. This will seldom happen except in the case of children; they will sometimes cry and scream and take deep and forcible inspirations. Under such circumstances, if the vapor of the anesthetic is concentrated, they may absorb into the blood, at one inspiration, sufficient of the anesthetic to completely paralyze the heart. I saw chloroform administered, under these circumstances, to a boy 14 years old. He was screaming at the top of his voice, and a napkin saturated with chloroform was placed over his mouth just as he took a powerful inspiration. Instantly his cry was checked, and he dropped as though he had been felled with a club. For a minute there was no sign of pulse or respiration, though I could hear a faint fluttering with my ear over his heart. In a moment there was a wavering pulse at the wrist, then it could be counted at 180. Respiration began slowly, and in ten minutes it was natural, but light, and the pulse had dropped to 120. The anesthetic was then resumed, though consciousness had not returned, and no further trouble was experienced. One can realize the character of the drug he is dealing with when it is known that a single inspiration of its vapor is capable of rendering a struggling boy instantly unconscious and keep him in that condition for ten minutes or more.

Ether and chloroform.—Ether should not be used on patients having diseased kidneys, as it may produce congestion of these organs and be followed by suppression of urine. Chloroform is less liable to produce this result. Ether is more dangerous than chloroform if the patient has atheromatous degeneration of the blood vessels. Ether stimulates the heart's action while chloroform depresses it, and any increase of pulse tension might rupture a diseased vessel. Emphysema, asthma and chronic bronchitis are aggravated by ether, and where these conditions exist chloroform is to be preferred. In administering ether it is very important to begin very slowly, as concentrated ether vapor, suddenly coming in contact with the mucous membrane of the respiratory tract, is very irritating and may produce spasm of the larynx. If given slowly there will be less trouble from the secretion of mucus in the mouth and throat; there will be less nausea afterward and the patient will recover more quickly. Death from ether is said to be by asphyxia and not from syncope, consequently respiration ceases first when death occurs. Ether is said to be safer than chloroform in the hands of the unskilled, but that should never be made an excuse for trusting this duty to the inexperienced, except where it is absolutely necessary. Unfortunately, the inexperienced are too often allowed to administer anesthetics without adequate supervision. Too often the anesthetist is more interested in the operation than he is in the administration of the anesthetic. This is wholly

inexcusable and should death occur under these circumstances it should be ascribed to criminal carelessness. Ether has been known to take fire fifteen feet from a gas jet, hence great care must be exercised in administering it at night. The container should be of tin, not of glass, and it should be securely corked in the intervals of use. The vapor is nearly twice as heavy as air, and in a still room it will settle to the floor and flow along it for a considerable distance before diffusing into the air. Hence a fire low down, as in a stove, is more dangerous than a gas jet high up.

When chloroform is used in a closed room, where there is a light, the vapor is decomposed, chlorine is set free, and some compounds formed which are very irritating to the respiratory tract. A towel saturated with ammonia and hung up, or a little ammonia scattered about will lessen this difficulty. Chloroform is more rapid in its action, less irritating to the respiratory passages, less unpleasant to the patient, less liable to cause nausea and vomiting, and produces less bad after-effects than ether.

The anesthetist should bear in mind that when the anesthesia is prolonged it will require less of the anesthetic to maintain that condition than it did at the beginning.

Breathing.—While every sign which will give any indication of the patient's condition, is important, the character of the breathing is most important of all. The ear rather than the eye should be depended on for the assurance that the patient is breathing properly, for the chest may continue to rise and fall regularly and no air enter the lungs. The ear will instantly detect this condition, as the sound of air entering the trachea and the bronchial tubes is unmistakable. Snoring is an assuring sound, but the stertor produced by a partial closure of the glottis is ominous, and the moment it is heard the jaw must be brought more forcibly forward; if it does not cease then, the anesthetic must be discontinued until the condition is corrected.

It sometimes happens that the patient will take a long inspiration, like a sigh, due to some manipulation of the surgeon; when this occurs, the inhaler must be removed until the breathing is again natural. It is not necessary nor is it advisable that the anesthetist should concentrate his attention on the breathing or, in fact, on any point; his ear should be so well trained that it will instantly call attention to the slightest change in the character of the respiration, even while his attention may be directed elsewhere. It not infrequently happens, when the patient is just sinking into unconsciousness, that he will hold his breath; if the pulse is good this is not alarming, and the inhaler need not be removed; however, if there is any doubt as to the condition, the anesthetic had better be stopped until breathing is normal.

I have anesthetized two such patients, and in both cases it was necessary to perform a sort of artificial respiration by strongly and intermittently compressing the chest before complete anesthesia could be produced.

The Pulse.—The anesthetist should keep one finger constantly on the facial or temporal artery; without directing much attention to the pulse he will thus be warned if any marked change takes place. At the beginning of anesthesia the pulse will often be very rapid, due to the excitement of the patient, but as soon as unconsciousness is complete, it usually be-

comes much slower. With chloroform, it will be weaker and with ether, stronger. If the pulse is intermittent before beginning the anesthetic, as in excessive users of tobacco, it forbodes trouble and it behooves the anesthetist to be especially on his guard and to have assistance at hand prepared for any emergency. I administered chloroform to a man with "tobacco heart" on three different occasions. On the first and second his respiration stopped twice and resuscitation was slow. At the third ordeal I succeeded in escaping this complication by stopping the anesthetic every few minutes. I once gave chloroform to a man for an exploratory laparotomy whose pulse went up to 180 as soon as I began and remained at or above that figure during the entire anesthesia. The diagnosis in this case was alcoholic liver. In severe operations it may sometimes happen that no pulse can be felt at the wrist when the hand is held up, but the pulse reappears when the hand is lowered. All sorts of variations of the pulse may exist without serious consequences resulting, but only the steady regular pulse is assuring to the anesthetist.

The pupils.—The appearance of the pupils furnishes valuable indications of the condition of the patient. On beginning the anesthetic they dilate, then contract till normal or a little smaller and usually remain contracted during the maintenance of safe anesthesia. If they are dilated and respond to light, it indicates that the anesthesia is not profound, if dilated and do not respond to light it indicates that the anesthetic has been pushed to a dangerous extent and it must be instantly stopped, the variations of the pupils in different individuals is so great that too much must not be risked on their appearance. Occasionally the pupils will be as small as pin heads. I do not know that this has any significance but I am never at ease under these circumstances until the operation is complete. It is well, in such cases, to inquire whether the patient may not have been given a dose of morphin a short time before. Occasionally, the pupils will be very much dilated throughout the anesthesia, and this too is a disquieting condition. In fact, any variation from the conditions usually witnessed is to be looked on with suspicion and the vigilance of the anesthetist redoubled. On one occasion an anesthetist watched a patient's pupil for ten minutes without seeing any change whatever, nor was it affected by light when the lid was raised. Becoming alarmed he looked at the other eye and found that pupil much smaller than its mate. He called the attention of the surgeons to the anomaly but they could offer no explanation. Picking up an instrument he touched the cornea with it and discovered that the eye was glass.

Color of the face and lips.—The color of the lips and face should be noted before beginning the anesthesia, for any marked change in their appearance indicates impending trouble. If the face becomes blue it shows that the patient is not getting enough air and the inhaler must be at once removed. I have on two or three occasions seen an ashy paleness suddenly spread over the face and in every case the patient had already, or immediately did, quit breathing. The color of the face is a valuable indicator in women, but is less useful in men. A patient with bright red lips or rosy cheeks is not in any immediate danger from the anesthetic.

Clothing.—The patient should have on no more clothing than is absolutely necessary and what cloth-

ing he has on should be easily removable so that if soiled, as is likely to be the case, it can be changed without too great disturbance of the patient. Clothing about the chest and throat should be loose. A woman wearing a corset is not a fit subject for an anesthetic. Care should be exercised that the surgeon or his assistants do not rest their elbows on the chest of the patient; they may unconsciously bear down so hard as to seriously interfere with respiration.

Position of the patient.—In giving anesthetics for dentists you must insist that the patient be placed in the recumbent position. Require the dentist to lower the chair till the patient is horizontal, then when the patient is asleep the chair may be raised a little so that the dentist can pull the teeth, but as soon as that is done the chair must be again arranged so that the patient's head is on a level with his feet.

Position of the arms.—The patient's arms should be folded across his chest unless in that position they interfere with the surgeon. They should not be raised above the head unless absolutely necessary as this position interferes with respiration. They should not be allowed to hang down over the edge of the table for this is liable to produce paralysis. I usually pin the sleeves of the patient's night dress across his chest. In putting the patient into bed care must be taken of the arms lest they become folded under the body, when a fracture or dislocation might easily occur.

While totally unconscious, the patient must be watched as closely after removal to the bed as while on the table, because moving is likely to cause vomiting and, unless care is taken, the vomited matter may be drawn into the lungs and do damage, even to complete suffocation.

Droppers and inhalers.—For chloroform, I use a common wire mask covered with one thickness of linen; for this purpose, I have pieces of old napkins or tablecloths. These are cut so as to project in a sort of ruffle, about an inch beyond the mask, all around except at the top where it is cut close to the wire in order to leave the eyes uncovered. This margin can be held down with the left hand if the patient is getting too large a proportion of air. These pieces of linen have two holes by which they are fastened to the mask and are bound on the edge with tape, or hemmed. These are used but once and then sent to the laundry. I know of no habit more filthy than that of anesthetizing patient after patient without changing the cover on the mask, as is done in some clinics.

For ether, I like the towel about a folded newspaper about as well as any of the elaborate patent inhalers in the market. Its simplicity and cleanliness are much in its favor, yet the ease with which the patient can be asphyxiated by a careless anesthetist renders it less satisfactory than it otherwise would be. For dropping chloroform, I use a two ounce bottle with a notched cork. A useful contrivance used by some anesthetists consists of a wick of cotton reaching from the bottom of the bottle to an inch or so outside of the cork, which is gently inserted into the mouth of the bottle. This acts on the principle of a capillary drain and the rate of flow is regulated by the angle at which the bottle is held and the tightness of the cork. I have never been able to satisfactorily regulate any of the patent droppers and regard them as wholly unnecessary. No special vessel is needed for ether, as it can be poured out of the container in which it is bought.

Preparation of the table.—In private houses where they do not have a trained nurse, the anesthetist should see that the table is properly prepared for the comfort and safety of the patient. To this end, fold a quilt or blanket lengthwise, twice, so that it will be four thicknesses; lay this on the table; cover it with several thicknesses of newspaper, and over this throw a sheet. The blanket will be longer than the table and the extra length can be folded under at the head for a pillow, this will make the patient's head lie more comfortably than it would on a perfectly level table, and an ordinary pillow is usually too high. If an emaciated patient lies on a hard table during a protracted operation, decubitus may ensue. These pressure ulcerations are very hard to cure and add very much to the gravity of the case. If there is a carpet on the floor of the room in which the operation is to take place, a lot of old newspapers spread on the floor will protect it from damage. Such a precaution will be appreciated by the family though they would not think of it unless mentioned.

In curetting and other vaginal operations where much water is used, the clothing sometimes gets saturated to the patient's head. If there is no appliance at hand, such as a rubber pad, to prevent this, it may be avoided in a large measure by placing a couple of blocks of wood under the legs at the head of the table.

Let every man who is called upon to administer an anesthetic give the strictest attention to his work, remembering that it is second in importance only to the work of the surgeon; that it often requires more skill than is required of the surgeon, and is frequently attended with greater danger to the patient than is the operation. Then there will be more skilled anesthetists and fewer "unavoidable" deaths from anesthetics.

200 Oakwood Boulevard.

OPERATIVE TREATMENT OF IRREDUCIBLE DISLOCATIONS OF THE SHOULDER JOINT, RECENT OR OLD, SIMPLE OR COMPLICATED.

BY EDMOND SOUCHON, M.D.

PROFESSOR OF ANATOMY AND CLINICAL SURGERY, TULANE UNIVERSITY,
FELLOW OF THE AMERICAN SURGICAL ASSOCIATION.
NEW ORLEANS, LA.

(Continued from page 1098.)

25. *Irreducible dislocations, old, spontaneous, or pathologic.*—No case similar to such cases of the coxo-femoral articulation has been found on record.

26. *Irreducible dislocations, old and paralytic,* are irreducible simply because they can not be kept reduced, although they are readily replaced in the socket, because the muscles have lost their power through paralysis of their nervous supply from peripheral or central causes. The peculiar joint diseases described by Charcot, specially in connection with locomotor ataxia, are also cases in point. The treatment should be directed to the cause. In irreducible old dislocations from paralysis of the deltoid, expose articular surfaces, pare them and let them become ankylosed. The following is a case in point: Julius Wolff, 1886.¹⁰⁸ Irreducible dislocation, old, downward (paralytic), posterior incision, reduction, stitching of head to glenoid cavity, result, improved. Male, aged 5 years. *Diagnosis:* This was a perpendicular luxation of the shoulder, downward, due to severe accident, and a traumatic myopathy. The head of the humerus had sunk about three centimeters from the acromion

and glenoid cavity, so that one could easily push a finger into the space between the head and the acromion. *Duration:* Three years. *Movements, etc.:* The right scapula is slightly dislocated on keeping the arm quiet. The lower angle of the scapula stands off from the thorax and the angle, and the lower part of the inner border is nearer the spinal column on the right than on the left side. The arm hangs close to the thorax and moves like a pendulum when the patient, by changing the position of his body, starts its movement, or when one pushes the arm in any position it will swing back and forth without the will of the patient. The humerus is thereby rotated inwardly, so that the greater tuberosity points inward and the lesser tuberosity backward. The sulcus (intertubercularis), between the tuberosities is easily palpable and appears as deep as in the dry bone specimen. Acromion processus coracoideus, and the upper rounded, depressed and lowered head are prominent and are easily distinguishable. Patient raises the scapula and abducts the angulus scapulæ. The arm does not follow the movements of the scapula. When the patient makes a great effort he can, for a moment, raise the caput humeri and scapula, so that it may be at its normal height. More certain, and then only for a moment, the caput humeri will reach its normal height by reflex when one gives the patient a sudden blow on the back. Should the patient desire to elevate the arm he moves it, with the body, outward, with a swinging motion, pendulum-like, and then catches the right hand with the left and raises it. Atrophy of the deltoid so marked that if one attempts to grasp it with the fingers almost nothing could be seized. The supraspinatus and pectoralis major muscles were less atrophied, as well as the muscles of the forearm. However, the muscle pectoralis major is weak and only acts on fixing the head of the humerus, whereas, the muscle latissimus dorsi is under the same circumstances stronger. Every other action of the shoulder joint is impossible. One can passively move the humerus in any position of luxation or subluxation. The shortening of the injured upper arm in comparison with that of the healthy was two centimeters, of the forearm and hand one centimeter. Movements of elevation were only possible when the child by movements of the body gave motion to the arm, like a pendulum. The upper arm is greatly atrophied, and that very evenly on the anterior and posterior surfaces. The elbow-joint, owing to the flaccid hanging arm, could not be moved. When the upper arm is elevated and fixed the patient is able to actively straighten the elbow when it has previously been passively bent, or if the patient has allowed it to fall by its own weight into a flexed position. If one fixes the upper arm, then rotates it firmly inward and elevates it to an angle of 45 degrees there is a possibility of weak active movements in the forearm. Pronation and supination of the forearm is slight, and only possible when the forearm is bent. The closing and stretching open of the hand, with finger movements, can be easily done. On the pectoralis major one notices fibrillar movement, particularly when one breathes or blows on that region. Sensation to pain, temperature and position is equal on both sides. No vasomotor disturbances exist. Eulenbarg's electric examination shows a marked decrease of nervous (irritation) excitement (faradic) in the axillaries and less in the plexus over the clavicle; no decrease in the other nerves of the arm. Marked decrease of faradic

muscular irritation in the deltoid, less decreased in biceps, triceps and supinator longus and no reduction of muscular irritability in the forearm muscles; marked decrease of galvanic muscular irritability in the deltoid; no arterial reaction. *Operation:* The arm was abducted so that the posterior border of the glenoid cavity could be easily palpated, and an incision was then made six centimeters long, beginning at the posterior angle of the acromion, along the posterior border of the glenoid cavity downward. This incision laid the joint open. The humerus was then rotated inwardly more than was natural and so much of the muscular insertions at the greater tuberosity as was necessary to permit of this abnormal rotation was cut away. This permitted a good apposition of the head of the humerus with the glenoid cavity, and after obtaining this marks were made on the head of the humerus and overlying the glenoid cavity, as it was intended to knit the humerus to the glenoid cavity by means of ivory pins. A thin layer of cartilage was then chiseled off the head and cavity and a hole drilled in the head of the humerus from the inner to the outer side, and on the border of the middle and outer third. In boring of the scapula it was sought to have the hole one centimeter from posterior border, for fear the bone would break off if the drilling were too near the border. In order to do this it was necessary to make a horizontal incision from the middle of the vertical one through the fibers of the infraspinatus. After boring the holes it was found that the ivory point could not be forced through both holes, as they were not in a straight line, therefore a strong silver wire was passed through both holes and then twisted until the chiseled surfaces of bone were in close apposition. The fixation was so complete that it was not necessary to make another knitting. The author then extirpated a portion of the articular capsule and left as much as would be necessary for the joint and closed the capsule with catgut stitches. Both muscle incisions were then closed with buried catgut suture and the skin wound closed, with the exception of a small point for drainage. *Result, immediate:* Primary union. *Result, remote:* Better than could have been hoped for. Patient can now, by means of scapula, lift and depress arm, which formerly dangled lifeless, and can also slightly abduct and adduct it. Against all expectation, it has happened that a form of new joint has developed, but with very limited motion, which does however permit rotation inward and outward, and even makes it possible upward and downward, no firm union having taken place between head of humerus and glenoid cavity. Head of humerus fixed to scapula. The author had hoped to obtain an osseous fixation of the denuded head and cavity, but did not succeed. It is therefore fixed by silver wire and by the fibrous tissue attached to the openings of the bored holes to the cicatrix, and we have therefore a new jointing with limited motion. There is slight rotation. Patient can throw a ball up or to the ground; can walk with a stick; can brush his shoes with the right hand, and can also write with it. None of these movements could be made before the operation. No marked progress in movements at the elbow. After the operation marked contractions were induced in the deltoid muscle, which previous to it did not react at all. This was the condition four months after the operation.

27. *Irreducible dislocation, old, complicated with persistent atrophy of the muscles or with muscles not responding to the electric test, should not be operated*

for obvious reasons unless to relieve troublesome pressure symptoms.

28. *Irreducible dislocation, old, complicated with fatty or sclerotic degeneration of the muscles; the same applies.* It is recognized by the fact that when under an anesthetic, while the muscles of the opposite shoulder are completely relaxed, yet those of the affected side are still rigid and tense and call for section of the unyielding muscles. This sclerotic and fatty condition is not rare in cases of ankylosis of old irreducible dislocations of the shoulder specially and is often one of the most potent factors in preventing the reduction of the bone even after the head has been excised.

29. *Irreducible dislocation, old, in subjects rheumatic or gouty; the same applies also because they are apt to be followed by ankylosis, specially if reduction has been done; these subjects manufacture fibrous tissue too readily.*

30. *Irreducible dislocation, old, complicated with diseases at large, should be treated with the greatest care.* Tripier's case is one in point.

31. *Irreducible dislocation, old, complicated from having been subjected to great efforts at reduction, should not be operated for some two or three weeks lest we find bruised tissues, extravasated blood, etc., which may be the causes of suppuration and sepsis.* Langenbeck, 1877, is one example; also Kocher's No. 3 and No. 6, 1889.

32. *Irreducible dislocation, old, complicated by arthritis acute, should not be operated until the acute state is over.*

33. *Irreducible dislocations, old, complicated with arthritis chronic or with suppuration, are reported by Reid 1878, Bardeleben 1889, Fender 1889, Schede's No. 2, 1892, Case 23, Bellamy 1887, Case 7. They should be operated as soon as possible.*

34. *Irreducible dislocation, old, complicated with ankylosis of the head in the pseudo-cavity, is mentioned by Post, 1861, and Hofmehl, 1881. They usually present great difficulties, specially if the ankylosis be fibrous and close, but particularly if it be osseous.*

35. *Irreducible dislocation, old, complicated with pressure symptoms of the vessels and nerves should be operated, if only for the relief to be obtained, provided no serious contraindications exist.*

36 and 37. *Irreducible dislocation, old, complicated with fractures during attempt at reduction soon before or during the operation.* If the fracture is very high up it is safest treated by resection of the broken head; when the fracture is in the middle the head should be resected below the ball and the balance of the fragment brought in apposition with the lower fragment. Thiersch's case, 1874, is an example. We will recall here the following cases of old dislocations and new fractures of Kocher, 1889.^m In case No. 2, one week before operating an attempt to reduce was made and the bone fractured through the anatomic neck; the greater tuberosity was torn off, also the subscapular, the short head of the biceps; the fractured head was resected or removed and the result was good. In case No. 4, attempt at reduction before operating was followed by fracture of the head of the humerus, the fracture line passing also through the greater tuberosity; resection of the head, result good. In case No. 5 there was an old united fracture of the head through anatomic neck and of the tuberosity; the bones were refractured in the manipulations

to try to reduce before operating; the fractured bones were removed, with an improvement of the case. The same accident, *i. e.*, refracture, happened to Edmann, 1896, and to Vander Veer, 1897.

38. *Irreducible dislocation, old, complicated with injury to the vessels before operating and followed by an operation* is represented by the clinical case of Lister, 1873, rupture of the axillary artery.

39. *Irreducible dislocation, old, complicated by injury to the vessels during operation* has been recorded in the case of Annandale, 1875 (circumflex and axillary arteries), Langenbeck No. 2, 1879 (subscapular artery), Hofwohl 1881, Volkmann 1882 (subclavian vein), Vander Veer, vein and artery—axillary. The injury to the vein rendering ligation necessary and followed by threatening gangrene, calls for deep consideration of the advisability of ligating the axillary or brachial artery below the largest collateral. Injury to both artery and vein or uncontrollable hemorrhage must be met as done by Vander Veer by amputation of shoulder.

40. *Irreducible dislocations, old, complicated with old fractures; non-united of the tuberosities*, call for the resection of those pieces which are usually connected by more or less numerous short, dense fibrous bands. Irreducible dislocation, old, complicated with old fractures united of the tuberosities, of the anatomic neck and of the surgical neck are common, 36 per cent. of all forward dislocations. They are usually osseous and surrounded by such a great amount of fibrous tissue or by such callus as to render the operation very difficult. The partial resection of the tuberosities is sometimes required to obtain room to work, as in the Bickham-Souchon case.

41. *Irreducible dislocations, old, complicated with old fracture united of the shaft*, are not likely to give trouble, being low down.

42. *Irreducible dislocations, old, complicated by a previous unsuccessful operation*, give great trouble, as proved by the case of Bickham and Souchon, where the adhesions between the surgical neck and surrounding parts were great and resistant; also between the cartilaginous surface of the head with the surrounding tissues: the head was much hypertrophied and had to be partially resected with the gouge and hammer to make room to continue the operation; it was also very hard, almost eburnated. All this, due to the long suppuration that followed the first attempt. Irreducible dislocations, old, recurrent or habitual are irreducible in that they can not be kept reduced.

43. *Irreducible dislocations, old, recurrent, treated by stitching of capsule (reefing)* are reported by Ricard, 1892, two cases.^{109 110} An anterior incision in the pectoro-deltoid interstice; at the upper end the incision is prolonged at right angle, following the contour of the insertion of the deltoid to the clavicle and acromion; the muscle is detached and turned outward and backward; the coraco-brachial is then lifted by an assistant, the operator frees the upper or inferior edge of the subscapular muscle at its humeral insertion; the arm is then rotated inward firmly, so that the anterior wall of the capsule is relieved of tension; then through the top of this wall, through this capsule and into the thickness of the subscapular muscle, the operator passes three stitches of coarse flat silk, vertically directed, and about two centimeters one from the other. The free extremities of these threads are tied two by two in order to reduce

this anterior wall to the least but most resistant and rigid thickness. There were no difficulties nor complications during the operation nor after; the results immediate were not mentioned. The patient is reported as keeping well during the nine months following the operation, when he was employed wheeling a wheelbarrow. This surely is the ideal operation for habitual dislocations.

44. *Irreducible dislocation, old, recurrent treated by incision of capsule, overlapping and stitching*, is the first case of operation reported for recurrent dislocation, by Samosch, in 1889.¹¹¹ Through an anterior incision the capsule was reached and split longitudinally; the medial portion was drawn over the lateral and pulled strongly and stitched in this position. No difficulties of complications are mentioned; the healing was primary and the final result very good.

45. *Irreducible dislocations, old, recurrent, treated by resection of portion of the capsule, stitching*. Three cases were found, one by Gerster, 1884,¹¹² and two by Burrell in 1897.^{113 114} Gerster's is a case where reduction was effected without any difficulty, the arm put up in a plaster bandage for five weeks. Upon the removal of the bandage the dislocation reappeared and the mere weight of the extremity alone was sufficient to cause the reappearance of the dislocation. An anterior incision was made and the capsule exposed; its inner aspect, the side facing the axilla, was abnormally relaxed; a piece one inch long and two in width was excised from it while the arm was firmly rotated outward. A counter incision was made into the posterior part of the capsule for drainage, closing of the anterior incision. There was no difficulty nor complication during the operation. Septic fever set in a few hours after, due to the catgut drain; it was removed and replaced by a drainage tube; wound treated openly. There was long suppuration with erysipelas. After the healing the functions of the joint were fair and promised to improve.

Burrell proceeds also through an anterior incision: the operations were more elaborate and systematic: they presented no difficulties nor complications, healed primarily and gave very good results. The cut which accompanies his description shows the field of operation: it is a drawing from a dissection made to demonstrate this operation by Dr. F. B. Lund. The important detail, which is shown in the cut, is the divided tendon of insertion of the pectoralis major. This allows the retraction inward of this muscle, uncovering the capsule of the joint. In order to gain access to the joint the subscapularis muscle should be partially divided. Then with hooked retractors a piece of the capsule can be excised.

The following description gives in detail the operation:⁷⁹ The patient was etherized and the arm slightly abducted. An incision was made from the coracoid process downward and outward, following the line of the cephalic vein, to below the upper border of the tendon of the insertion of the pectoralis major. The cephalic vein was then recognized, drawn outward and the intermuscular septum between the deltoid and the pectoralis major was separated with the handle of the scalpel and with a few touches of the blade. This exposed in the upper part of the wound, the coracobrachialis and short head of the biceps, and in the lower angle of the wound the upper part of the insertion of the pectoralis major.⁸⁰ The acromio-thoracic artery was distinguished: the upper three-quarters of the insertion of the pectoralis major was divided in

order to allow the muscle to be retracted inward and thoroughly expose the head and neck of the bone. These now came into view, and in front of the head and neck of the bone, could be seen and felt, through its sheath, the long head of the biceps. It was found necessary to clear the tendon of the coraco-brachialis and short head of the biceps quite up to the coracoid process, and to carry the incision in its whole depth up to the coracoid process.⁵¹ By externally rotating the arm and dropping it backward the insertion of the subscapularis muscle could be distinguished and its tendon was stretched over the head of the bone. A portion of this insertion was divided. The finger felt the head of the bone, the anterior two-thirds of which was very plainly exposed, and it tended to slip forward toward the coracoid process. The coracoid process could be plainly distinguished and the capsular ligament was apparently lengthened.⁵² The arm was then abducted to an angle of 45 degrees and the head of the bone pressed backward to prevent the head from coming up under the coracoid process. By these means the front of the capsule was relaxed. The loose part of the front of the capsule was grasped with a three-pronged vulsellum forceps. Three sutures were inserted with a curved needle beneath this and this fold of the capsule was excised, three-quarters of an inch in length and five-eighths of an inch in width.⁵³ Two of the sutures were cut out at the time of removing the bit of the capsule. The other suture held and was tied. Another suture was introduced into the capsule. After these sutures were tightened and tied it was found that the capsule was distinctly tighter and shorter.⁵⁴ The acromio-thoracic artery was divided and was the only vessel requiring ligature. Sterile water was used for irrigation. Silk-worm gut sutures closed the whole length of the wound. No attempt was made to unite the partially divided insertions of the pectoralis major and of the subscapularis: as when the arm was brought to the side these structures came together without suturing. The wound was dried, an antiseptic dressing applied, and the arm was fixed to the side with the hand across the chest.⁵⁵ A clear differentiation must be made of all the anatomical structures, and with this accomplished, the operation is feasible. The use of broad retractors without sharp points, on the inner side of the wound to retract the coraco-brachialis and the vessels, is of great importance.⁵⁶ The important steps in the operation are, the free division of the tendinous insertion of the pectoralis major for three-quarters of its breadth, in order that the head of the bone and capsular ligament may be freely exposed by retracting the muscle; the division of a portion of the insertion of the subscapularis; raising the arm to a horizontal plane and pressing back the head of the bone, which relaxes the front of the capsule so that it can be grasped and a bit removed.⁵⁷

The result of the operation in the first case is that a year and ten months after the operation the patient stated that there had been no recurrence of the dislocation: that he had been fishing on the Grand Banks during the summer of 1896, and that the motions of the joint were perfect. In the second case at the end of two months the patient is using the arm freely and has had no recurrence of the dislocation.⁵⁸

The first operation took one and three-quarter hours. The second thirty-five minutes. It is purely an anatomical operation and each anatomical structure must be recognized as carefully as in the ligation of an

artery. So far as one can generalize from these two operations, it is simple, efficient and curative.⁵⁹ This operation is a more severe one than mere stitching and should be reserved for when the stitching fails.

46. *Irreducible dislocation, old, and recurrent treated by reduction.*—There is one case reported by Albert, 1888.¹¹⁵ It was of sixteen months standing. The joint was penetrated through a posterior incision. The head and glenoid cavity were deprived of their cartilage and stitched together. No complications followed the operation, but it resulted finally into ankylosis of the joint.

47. *Irreducible dislocations, old, recurrent, treated by resection of the head.*—Cases were reported by Cramer 1882,¹¹⁶ Popke 1882,¹¹⁷ Sacré 1883,¹¹⁸ and Owen's No. 2, 1893,¹¹⁹ Monks 1896.¹²⁰ They were all subcoracoid dislocations. The operation consisted in an anterior incision: Langenbeck acromio-humeral was used by Cramer. There were no difficulties or complications during the operation, nor any complications after. They all healed by first intention except Popke's case. The results, remote, were: fair in the case of Cramer and Owen, good in Sacré's and improved in Monk's. This operation appears as a rather severe one when contrasted with the result of Ricard. It is true in the latter's case there was no rent of the capsule; but when this exists it should be pared and stitched. Excision of the head of the humerus is a mutilating operation and will be very rarely necessary. It is conceivable that after an exploration of the joint, abnormalities might be found which would demand an excision.⁶⁰

48. *Irreducible dislocation, old, operated by resection and reduction and followed by long suppuration,* has been met with in 32 per cent. of all forward dislocations. This is indeed too much and calls for the greatest care in asepsis and antisepsis in the future. The head had also to be resected after reduction in the case of Kocher No. 3, 1889, a case of forward dislocation operated through an axillary incision; also Socin's case, 1886, downward dislocation—reduction, necrotic pieces, then resection; also in Schede's case No. 3, 1892, backward dislocation—congenital reduction, necrosis of greater tuberosity. The same remarks apply here with much greater force. It shows also how considerate the surgeon should be before reducing instead of resecting.

49. *Irreducible dislocation, old, operated by resection or reduction and followed by necrosis of the bones,* is recorded in 2 per cent. of the resected cases, as against 16 per cent. of the cases reduced of forward dislocation.

50. *Irreducible dislocation, old, operated by reduction and followed by ankylosis of the head in the old glenoid cavity,* is one of the dangers inherent to reductions. It has been observed specially when the surfaces were tightly bound down and when the after-treatment had not been most carefully attended to from the beginning.

51. *Irreducible dislocations, old, operated successfully by reduction,* may be followed by recurrence and ankylosis in the pseudo-cavity.

52. *Irreducible dislocations, old, operated by resection and followed by ankylosis of the sectioned extremity of the humerus in or near the glenoid cavity,* have been observed, specially in the case of Kocher's No. 1, 1889, and of Bickham's and Souchon's, 1895. Cases requiring the resection of the superficial part of the head are apt to be followed by ankylosis.

For this reason it is best in adults to resect more extensively than is actually necessary to produce movement, but in young subjects, especially in children, the great importance of not injuring the epiphyseal cartilage will render the opposite course the rule to be guided by. This ankylosis of the sectioned extremity may require either section of the muscles or resection of the ankylosed extremity. The latter is often a laborious undertaking, on account of the extensive and resistant adhesions, due to the fact that the parts have been operated upon before. The muscles are also retracted and degenerated in these cases. This condition is often due to improper consecutive or after-treatment, either because it was not begun soon enough or because it was not kept up long enough.

53. *Irreducible dislocation, old, operated by resection is followed by dislocation of the sectioned extremity of the humerus under or inside of the coracoid process*, sometimes forms a coraco-humeral articulation, instead of a glenoido-humeral, or under the clavicle. Ollier mentions a case where he had much trouble in preventing it. It is usually the result of improper attention to after-treatment at the proper time. In one case, Luckie's, the resected extremity articulated with the under surface of the acromion. (Ollier.) Such occurrences interfere very much with the movements and may destroy the results of the operation. There was an articular capsule between the humerus and the inferior surface of the acromion. This later was covered with fibrous tissue, the small humeral head which projected into the capsule is a small projection as large as a pea, which was lined with hyalin cartilage. Outside of the articulation osteophytic processes extended into the muscular insertions; the glenoid cavity was lined with fibrous tissue and connected with the humerus by bands of connective tissue.⁹¹ The case was an old patient of Langenbeck (it is related in Luckie).

54. *Irreducible dislocation, old, operated by resection*, is sometimes followed by ankylosis of the sectioned extremity of the humerus under or inside of the coracoid process.

55. *Irreducible dislocation, old, operated and followed by ankylosis of the pseudo-joint, due to hypertrophy or irregularity of the new ossification*, is only seen in cases of subperiosteal resections. New resection may be attempted, but may not do much good, on account of the condition of the tissues of the region. If there is only one bony projection it should be excised. (Ollier.)

56. *Irreducible dislocation, old, operated and followed by dry arthritis of the pseudo-joint*, is observed specially after reduction, but also after resection, when the subperiosteal method has been followed and a new head has been formed. It should be treated on general principles, unless too painful, when a new resection has to be made, but extra-periosteally. After a few years they present modifications analogous to those of ordinary dry arthritis. The joint becomes stiff and cracks. This is especially observed in rheumatic and tuberculous subjects; in the latter caries may develop. (Ollier.)

57. *Irreducible dislocation, old, operated by resection and followed by a dangling arm*, is often the result of an extensive resection, or an unnatural condition of the muscles. Prosthetic apparatuses place the arm in the same condition as if it was ankylosed. When the distance between the resected humerus and the glenoid cavity is only six or seven centimeters the

extremity should be pared and stitched to the glenoid. When the distance is greater the same should be done and the bone stitched as high up as possible. Bone-grafting may be very useful, especially fragmentary grafting. (Ollier.)

Remarks concerning the operations, specially by resection.—The following points from able authorities, but mostly from the admirable book of Ollier,¹²² should be well borne in mind by operators, especially in operations by resection. They are transcribed here from a previous paper by the writer, on ankylosis of the shoulder.¹²³

Lagrange states that Boucher was the first who thought of resecting the upper extremity of the humerus, but it was White of England and Vigaros in France who performed the first operation.¹²⁴ In 1789 a boy presented, with his right hand, to the Academy of Surgery the head of his right humerus, which had been resected by the surgeon-major of the regiment, du Barri.¹²⁵ But Ollier asserts that Bent of Newcastle, in 1771, is really the first who resected the humeral head.¹²⁶ Post of New York was the first to resect for irreducible dislocation; the next was Warren of Baltimore, says Ollier.¹²⁷ However, we report a case of Langenbeck dated 1858. Ollier was the first to recommend (1858) the preservation of the capsulo-periosteal sheath without cutting the muscles, as a means of obtaining a new joint, and if possible to cause the formation of a new head.

Langenbeck's incision, starting farther behind the internal border of the acromion, sacrifices the innervation of a greater portion of the deltoid.¹²⁸ Ollier's rule is to expose the head by an incision as near as possible to the antero-internal border of the deltoid and, if necessary, by the disinsertion of the internal portion.¹²⁹ The incision should never be made internally (in axilla) on account of the nerves and vessels, except in rare cases of subglenoid dislocation where the head projects beneath the skin.¹³⁰

The deltoid is the most important of all the muscles, as is demonstrated by the cases of paralysis of the circumflex nerve, when the insufficiency of the muscles which are inserted on the head becomes evident. The preservation of the circumflex nerve is also of great importance.¹³¹ This nerve runs parallel to the posterior border of the acromion, from which it is distant in an ordinary adult by five and a half or six centimeters. This is important for the limit of perpendicular incision and for the incision for the drainage tube behind.¹³²

The loss of the elevating action of the deltoid must be accepted, like the loss of the rotating power from the divisions of the muscular insertions into the two tubercles, as a necessary consequence of resection of the head of the humerus. But the holding or supporting power of this muscle, exerted upon the whole of the upper extremity, owing to its position, its extensive origin and the manner in which it embraces and protects the mutilated parts as well as its faculty of carrying the arm backward and forward, are all functions which may still remain and serve to point to the great importance of preserving its integrity as fully as possible. The wasting of the internal fibers, however, seems a necessary result of resection by the single incision, but it has this compensating feature, that it is a less serious loss to the patient than an atrophied condition of the outer and posterior fibers would be, because the upper clavicular fibers of the great pectoral can take the place of the

inner deltoid fibers to a considerable extent in supporting the shoulder and drawing it forward to the chest.¹³³ The movements of elevation are seldom required save by those who follow climbing occupations, as sailors, masons, etc.

The mode of performing the operation as well as the operation itself will naturally influence these movements. If the deltoid be cut completely across by means of an elliptical incision, the power of abduction of the arm and its elevation may be permanently lost. If its fibers be merely split by a longitudinal incision they may be preserved or regained in great part.¹³⁴ The incision should be as far forward as possible, because all that portion of the muscle which will be to the inner side will be paralyzed. It is best to avoid the interdeltoideo-pectoral groove on account of the cephalic vein; make the incision a little behind.¹³⁵ In exceptional cases the clavicular portion of the deltoid may be disinserted, *i. e.*, by section of the insertion near the bone without preserving the continuity with the periosteum. It is different from the subperiosteal detachment of the muscle done with the gouge. The disinsertion of the clavicular portion of the deltoid, in part or in totality, is especially indicated when the head of the humerus is bound down and the arm can not be separated from the chest.¹³⁶

The relations of the large vessels and nerves must not be overlooked. However, in subperiosteal-capsular resections they run no risk as long as the operator remains within the capsulo-periosteal sheath.¹³⁷ A great effort should always be made to recognize the tendon of the biceps and take care of it. If torn or cut it must be stitched back. To obtain satisfactory results, especially in reductions, it is the posterior part of the capsule that the surgeon must get out of the way of the humerus, and of the cup. Therefore it is particularly behind the displaced head that he should dissect and not so much in front as has been done hitherto.¹³⁹

As one of the chief defects of the operation is the poor amount of adduction and elevation which remains, owing, in a large measure, to the humerus being too short to be brought into the glenoid cavity when the deltoid acts, Holmes thinks that in this joint a trial of the subperiosteal method should be carefully made to insure as much reproduction of bone as possible.¹³⁸ The resection should be done economically. First saw through the anatomic neck (see Kocher, No. 3, 1889). If the reduction is not possible saw off a slice and then try to reduce; if necessary saw off another slice or saw through the surgical neck. When the humerus is put back in place it must be neither too loose, because there will result a flake limb, nor too tight, because it may become ankylosed partially or totally; this has often happened¹⁴⁰ and is worse than a loose joint.

Ollier says to be careful about the replacing of the extremity of the humerus because the fibrous tissue might form a sort of interarticular cartilage between the end of the humerus and the cup. It will be well to stitch together the fibrous tissues so as to form a sort of capsule.¹⁴¹ It is impossible to say how much of the head must be resected to reduce the dislocation. Sometimes a superficial resection of the convex articular surface is sufficient to replace the head, but it must be remembered that the head must be maintained in the cup. A resection below the head insures a better false joint. A too close resection may be followed by ankylosis.¹⁴² Only the head of the humerus,

without any of the shaft, should be removed. However, it is best to remove too much of the head than not enough. The subperiosteal is the best method; too much dissection of the bone may cause necrosis.¹⁴³ After the head has been resected, the cup should be cleared so as to be sure that the extremity of the humerus will readily remain in the cavity, otherwise that extremity itself may become displaced (or dislocated) under or inside of the coracoid process.¹⁴⁴ When feasible, the capsule should be restored as much as possible over the reduced head or over the resected extremity.

Ollier described several cases of reproduction of bone after the subperiosteal method.¹⁴⁵ Langenbeck mentions a case in which the whole shaft of the humerus was necrosed and was removed, the elbow joint was resected at the same time and yet the reproduction of bone was so complete that the shortening was no more than one and one-fifth inches. The new humerus broke several times, but the movements of the shoulder and elbow were satisfactory and the hand capable of the most delicate movements.¹⁴⁶

In cases of rarefaction of the bones it is important to seize the head with strong tooth forceps or rotating forceps; ordinary forceps smash the head.¹⁴⁷ The posterior drainage incision must be made at the most dependent part when the patient is lying down; this depends upon where the resection has been made. Care should be taken not to wound the circumflex nerve nor the artery. When the incision is made very low down, it is the musculo-spiral nerve that must not be wounded.¹⁴⁸ It is best to place the tube even in cases where the bones are not diseased.¹⁴⁹ In adults the rule is to push the resected extremity into the glenoid cavity when regeneration of the bone is not expected.¹⁵¹ A thick pad should be placed in the axilla to prevent the humerus from being drawn inward. The preservation of the deltoid roundness is a peculiarity of the subperiosteal resection.¹⁵¹

Remarks concerning the after-treatment.—The sooner the passive movements are begun the better, a few days after the operation, because the resected humerus may become ankylosed.¹⁵² The more the wound healing progresses the more the movements should be extended.¹⁵³ The muscles, especially the deltoid, must be soon massaged and electrified. It is especially in operations on the shoulder that the after-treatment is of importance. Too much care can not be given to that after-treatment; if incomplete or stopped too soon, almost all the benefits of the operation may or will be lost.¹⁵⁴ It must be kept up for weeks and even months.¹⁵⁵

Extensive movements, especially those of abduction, should not be practiced until several weeks after the humerus is sufficiently fixed in the glenoid cavity, but the resected humerus may pass under the coracoid process, where it may form a coracoid articulation instead of a glenoid.¹⁵⁶

The re-establishment of the complete mobility is retarded by thickening of the capsule, which in some cases is shrunken and in some points is as resistant as cicatricial tissue; also to the adhesions of the tendons and muscles with the surrounding tissues, also to the fibrous and fatty degeneration of the muscles.¹⁵⁷ This condition of the muscles is all the more difficult to overcome because the other muscles instinctively take their place, especially those that move the scapula.¹⁵⁸ Rotatory movements must be begun as soon as there is no pain.¹⁵⁹ Electricity, massage, gymnastic exer-

cises must be conducted slowly, carefully, but continuously, every day.¹⁶⁰

Remarks concerning the final results.—In a number of cases of resection of the head operated on by Percy (1795) for various causes, the movements were all good except that of elevation, and the arm had to be rested against the chest to work the forearm, which then enjoyed all its strength.¹⁶¹

In order to appreciate the usefulness of the new joint, the following maneuvers should be practiced: To measure the force of the abduction, *i. e.*, of the action of the deltoid, weights should be fastened to the elbow, and the patient directed to raise the elbow outward, first before and then after fixing the scapula. Then do the same with the weights attached to the forearm or placed in the hand.¹⁶²

To measure the movements of rotation, flex the forearm against the anterior surface of the thorax, and place some article in the hand; then fix the elbow and make the hand describe the arc of a circle from within outward, keeping the elbow well fixed.¹⁶³ In doing this we must watch the actions of the other muscles inserted in the humerus, which by the successive contractions of their various parts may, at a given time, become rotators.¹⁶⁴ The patient should be made to cross the arms, to place the operated arm behind the head, on the forehead, behind the back, on the buttocks, throw a stone, etc.¹⁶⁵ Some patients may perform some energetic movements and yet feel hampered in delicate movements requiring rotation. The resistance of a fibrous band or the existence of an abnormal projection on the new head explains these discrepancies.¹⁶⁶

As for the conditions of the new joint, after resection from various causes, out of 213 resections, Gurlt observed 96 tight articulations, 21 anchyloses and 76 dangling limbs.¹⁶⁷

Remarks concerning the findings at the autopsies of operated cases.—In some cases there is formation of a new head more or less irregular.¹⁶⁸ These gave an almost ideal result. In one case Testor found an intra-articular cartilage.¹⁶⁹ Chaussier, Roux, Syme, Breuss, Hutchinson and others have dissected articulations of shoulders resected, from three months to twenty years. They all found a fibrous cord, strong and resistant, joining the humerus to the scapula, and adherent by its external surface to the surrounding soft parts more or less atrophied. But they never found a real articulation.¹⁷⁰ Ollier reports several cases of reproduction of bone after operation, found at the autopsies.¹⁷¹

OBSERVATIONS ON WHEN TO APPLY HEAT AND COLD IN EYE TREATMENT.

Read before the Wayne County Medical Society Nov. 4, 1897.

BY WM. H. POOLE, M.D.

DETROIT, MICH.

It is an undisputed fact that what are generally considered the simple things in the treatment of diseased conditions, whether medical or surgical, may if overlooked or misapplied, become serious, and sometimes be the means of bringing about untoward results. With this idea in mind, I have jotted down a few suggestions on when to apply heat and cold in eye treatment: not that these thoughts are entirely original, but in the hope that they may serve to remind us of a simple though useful adjunct, to our other treatment of the conditions mentioned as they may appear before us from time to time.

When we consider the general arrangement of the different tissues of the eye and its coverings, we are not astonished at observing the marked impression made upon the temperature of the different parts of the eye by the application of heat or cold, and we quite readily realize that the effect produced bears a direct ratio to the length of time of the application. In addition, however, to the influence which these agents exert on the temperature of the several parts of the eye, they exercise a controlling influence upon the circulation, which is fully as important and necessary to be borne in mind. While it is an old rule, that the temperature of the application which is most agreeable to the patient indicates which should be used, yet this can not be relied on absolutely, as instanced in many cases of external inflammations, where in the early stage hot applications afford relief, yet if persisted in too long edematous effusion ensues and possibly ulceration of the cornea with a lengthening out of the attack.

Either the dry or moist form of application may be made use of, but it is conclusively shown that better results obtain from moist applications, either hot or cold, not the least advantage possessed by moisture over the dry application, being the fact that it aids in keeping the conjunctival sac free of the unhealthy secretions. Moist applications possess more intensity of action, as is shown by the fact that the temperature is reduced much more rapidly by moist than dry cold: while on the other hand moist heat penetrates deeper and is more varied in the degree of heat obtained.

Both heat and cold exert a favorable germicidal influence. Cold, of no greater degree than can be well borne by the eye, prevents the growth and development of germs, and we well know that heat destroys many bacteria, a hot corrosive sublimate solution being over five times as effectual as a cold one. Of the external applications water is most frequently used, the effect being modified remarkably by the different degrees of temperature and the manner in which it is applied. For toilet purposes, in the majority of cases, more comfort will be derived from warm applications to the eyes, and the addition of a small quantity of boric acid to the water will be greatly

appreciated. Immersing the face in cold water and opening the eyes, as practiced by some, is to be deprecated, as the human eye is not suited to such treatment.

We will now consider more particularly the therapeutic application of these remedial agents, in some of the diseased conditions we see in our daily treatment of the eye. First, we may state as a general proposition that cold causes constriction of the capillaries, thereby checking the amount of secretion and exudation, and in this way acts as a sedative, relieving the pain in the beginning of acute inflammatory conditions.

On the other hand, hot applications are more useful in the later stages, bringing about a more healthy condition of the tissues involved, and relieving pain by stimulating absorption of the exudate and dilating the capillaries, not only in this way modifying the engorgement, but conveying to the part the life-giving principle for its proper nourishment. Again, we find that the quantity of a drug absorbed and the rapidity with which absorption takes place is greatly increased by the previous application of moist heat. This fact is frequently made use of when using mydriatics. In some cases of iritis, where owing to synechiæ the drug seems to make very little impression on the pupil, if we bathe the eye for eight or ten minutes with water as hot as the patient can bear, we will find absorption take place rapidly and we will get the desired action of the drug.

While moist applications are preferable, there are some cases where dry heat is more applicable and satisfactory, such as scleritis and iritis, where there is apt to be little or no secretion except of tears by reflex irritation.

We will find cold applications more suitable in the following conditions, viz.:

In conjunctival hyperemia, which consists almost exclusively in congestion of the vessels, with slight papillary engorgement, a very moderate increase in the secretion and with no swelling of the membrane, whether it is of traumatic origin or caused by eye-strain, the application of the cold douche or bathing with cold water for a few minutes, will be very effectual in bringing about a healthy condition of the membrane, care being exercised in not using water too cold or the reaction may be too severe.

In acute purulent conjunctivitis, which, as its name indicates, is characterized by a distinctly purulent discharge, thus differing from catarrhal conjunctivitis, for as Dr. Wecker says, "let a catarrh be never so intense it will not give rise to true blennorrhœa or purulence." We need vigorous treatment from the beginning and as an adjunct to other treatment, to assuage the initial swelling and pain we use ice cold applications, either by using bits of muslin dipped in iced water, changing them every minute so that the cold may exercise its beneficial influence; or in some cases, if the eye will bear it, small pieces of ice wrapped in muslin may be held on the eye. We need have no dread of untoward results from prolonged use as the rule, especially in the early stages of this form of disease, is continuous cold to the degree of toleration. These applications are to be continued day and night, ever being watchful of the cornea to see that it is not becoming involved, in which case the cold applications must cease and be succeeded by hot applications persistently, at least four times an hour for three or four hours, by which time usually the threatened destruction of the cornea will have been stopped, owing to the improved circulation and nutrition.

In ophthalmia neonatorum, cold applied in the same manner will be found just as useful and grateful to the little patient.

Cold applications are also sometimes useful in cases of phlyctenular conjunctivitis when, owing to the distressing photophobia, we can not get the patient to open the eyelids for the necessary remedies to be used, we drop a few drops of ice water on the eye, which penetrate between the lids and aid us in gently opening them.

Sometimes in penetrating traumatism of the eye where injury has been done to the iris and the lens, causing plastic iritis and traumatic cataract; ice cold applications are useful for their germicidal action as well as for overcoming inflammatory reaction.

We will now mention a few conditions where hot applications are more suitable than cold:

First, in acute catarrhal conjunctivitis, which while it may present somewhat the same symptoms we found in hyperemia, yet we have here a characteristic stringy, tenacious, flocculent, mucous discharge, with possibly some small masses of pus in it, having a tendency to stick the lashes together. At the very beginning of this condition we frequently find lukewarm applications very comforting and useful, but the error must be avoided of keeping up the treatment too steadily, as is sometimes done by the laity, who frequently make use also of such appliances as potato scrapings, bread and milk poultices, raw oysters, tea leaves, rotten apples and other disgusting substances, causing edema of the lids and conjunctivæ, intensifying the hyperemia, and finally, in some cases, producing ulceration of the cornea. Such conditions are not rarely met with in the clinics of public institutions.

In edematous conjunctivitis, a condition in which the hyperemia is not marked, where there is little pain and not much discharge, but a considerable effusion of serum beneath the conjunctivæ of both the eye and lids, causing a very uncomfortable swelling, bathing with lukewarm water will prove beneficial.

In trachoma, at the beginning of the disease, hot water is not usually well borne. As soon, however, as vascularity of the cornea arises with threatened ulceration, hot applications are indicated to stay the progress of destruction and assist in its repair. Hot compresses are oft times useful in causing the disappearance of the pannus by the inflammatory reaction which they promote.

In the less severe cases of phlyctenular conjunctivitis, lukewarm water will be very comforting and beneficial, helping to overcome the eruptive exudate.

In all forms of keratitis, hot applications are to be used, never cold, except possibly in phlyctenular, when ice cold water may be made use of for the immediate purpose of overcoming the photophobia, as referred to when speaking of phlyctenular conjunctivitis. This is practically the only time we use cold applications in corneal diseases.

The applicability of heat in diseases of the cornea will be well understood if we remember the anatomic structure of this membrane, it being non-vascular and dependent upon the surrounding tissues for nutriment, it follows that inflammatory or diseased conditions necessarily stop the supply of nourishment and death and destruction of the cornea results, as is evidenced by the ulceration. In order, therefore, to hasten the repair of the tissue it is necessary to overcome this stasis, which is accomplished by applying hot water, or sometimes better by dry heat, by folding

a napkin and heating it by the fire or with a hot iron.

Phlyctenular keratitis is undoubtedly the form which furnishes the majority of cases of corneal disease, occurring as it does among children who are delicate, ill fed, overfed or scrofulous, and in this class of cases we also see the disastrous results of ignorant interference in treatment by poulticing with the several harmful and repugnant articles mentioned previously, instead of using the simpler and more beneficial hot water compress.

On account of its stimulating properties, the hot compress will be found especially useful in the treatment of ulcers that do not heal readily, hastening the process of repair, while a drop or two of scalding water applied to a fungoid ulcer gives good results.

In suppurative choroiditis we find that hot applications are not only appreciated by the patient but are very beneficial, especially in mild cases.

Hot applications are often very grateful in muscular asthenopia, allaying the pain, and by stimulating the weaker muscle, removing the troublesome symptoms.

In a general way we may say the rule in all the milder cases, is intermittent use of the local applications of both heat and cold, from ten to thirty minutes at a time, and from three to ten times in the twenty-four hours, the continuous use of the applications being indicated only in the severer forms or in special cases.

270 Woodward Ave.

A CASE OF TACHYCARDIA.

Reported at meeting of the Toledo Medical Club.

BY J. L. TRACY, M.D.

TOLEDO, OHIO.

Mrs. —, aged 40, has many times during the last ten years told me about attacks of palpitation which she has had and which have come on suddenly, lasted from a few seconds to ten minutes and then as suddenly stopped. Many times I have been sent for when she had been having the attacks, but the heart would have quieted before I reached her. After an attack had passed off she would be weak and exhausted for a few hours, and then be in her usual health, which in appearance was a little below normal. I could never discover any organic trouble of the heart, nor of any other organ.

Occasionally she would have attacks of urticaria, and 0.13 gram of quinia would produce intense redness all over her body. As often as every three months she had attacks of bronchial irritation, coughing almost incessantly for an hour at a time, and raising great quantities of thick stringy mucus, these attacks lasting for about a week. The bowels are usually very loose, often moving four times a day for weeks at a time. The urine is usually scanty and high colored and causes much irritation.

I was called to see her and found her sitting in a chair, pale, breathing hard and absolutely pulseless. Every few minutes she had attacks of blindness. She said she felt as if falling or floating through the air. The heart was beating much faster than I could count and, if such a thing is possible, I believe it was beating three hundred times a minute. There was this peculiar thing about the heart sounds, that while it was beating so rapidly both the first and second sound could be distinctly heard; not that both would be heard in any one beat, but by taking the attention from the first sound the second could be heard. The heart had been beating that way for two hours.

I gave her morphia and atropia. The woman was not excited, but was in great distress. Extremities were pulseless and cold. Her feet were put into hot mustard water and I watched the effect of the hypodermics. Before I could tell what effect the morphia was having I decided to give her strychnia, and in about ten minutes it seemed that the heart was beating a little slower, and I gave her 0.0003 gram of nitroglycerin. Soon afterward she began to feel better and in two hours, as near as I could count, the heart was beating two hundred to the minute. About four hours afterward the heart began to intermit; the pupils became widely dilated; respiration was hurried; cold sweat all over the body; she could not see at all; complained of a sensation of sinking and I thought she was dying.

I gave her, in rapid succession, nitroglycerin and strychnia and she soon rallied and the pulse became regular and slow enough so that one could give a reasonable guess as to how fast it was beating, not less than two hundred. She was kept upon full doses of strychnia. About 6 P.M. she began vomiting and continued to vomit, at short intervals, until next morning.

The pulse remained at two hundred until 8 P.M., having been at the rate of two hundred and upward for twelve hours; after that time it became slower and the following day when the patient was quiet in bed, was 84.

There is a history of some special trouble when a child, of intense frequent headache for many years afterward, until she was fitted with lenses, since which time her headaches have recurred at long intervals only.

Riding upon steam cars had always caused dizziness. Turning over in bed often causes the same sensation; looking at moving objects, like the crowds upon the street, will do the same thing. Going up stairs has, for years, brought on palpitation. In summer walking out of doors makes her feel better, but in cold weather the palpitation with a feeling of suffocation comes on as soon as she goes into the cold air.

Her father, who is about 75 years old, has attacks of palpitation and a sister died of heart trouble at the age of 30.

This case suggests many conditions as the probable cause of the trouble. I have thought of eye strain, disease of the internal ear, aneurysm or pressure of something else upon the sympathetic, by which the nerve has been irritated or else by which inhibition has been cut off. I have looked for digestive disturbances that could possibly cause the trouble reflexly. Dr. Collamore called my attention to a mitral regurgitation which I think is not always noticeable. The heart is hypertrophied.

The attack referred to above occurred five weeks ago, since that time she has taken, as seemed required, strychnia, digitalis or strophanthus, principally the latter, and effervescent carbonate of lithia. For two weeks she remained in bed, then began sitting in a chair, and against advice, went down stairs. Tuesday, two days after, she did not feel so well. Wednesday her heart was beating two hundred per minute. In the evening she became nauseated and vomited all night. The entire body, as well as the bed, could be seen to vibrate with the action of the heart. I could not tell whether the rapid action of the heart caused the vomiting or the nausea induced the rapid action of the heart, or whether there was any connection

between them. I believe that the best treatment is rest in bed. Strophanthus seems to control the heart better than digitalis. Sleeplessness is troublesome. When her heart is troubling her she has insatiable thirst, the extremities are cold and sweat profusely. At such times, every few minutes, a sensation of tightness starts from the stomach and passes rapidly to the head, when she feels as if a violent stream of hot water had struck the top of her head. This sensation passes rapidly down over the body to the stomach and arms to the finger tips. Some authors say that tachycardia resembles epilepsy.

The patient's skin is always very pale, though her lips have a good color. The urine is loaded with urates, which prove to be principally soda and ammonium. I could find no casts.

NOTE.—The patient has since died in a condition of general anasarca.

DISCUSSION.

Dr. COLLAMORE thought medicines were likely to do no good.

Dr. FABER said that at the Hospital for the Insane he had frequently seen cases of rapid heart due to hysteria, and was inclined to that diagnosis. He argued that absence of fear as to results on the part of the patient, the aura described in the report and the general condition of the patient indicated that trouble.

Dr. LANDMAN had found far-sighted astigmatism, no hyperemia or anemia of cornea. Thought that dilated pupils pointed to pressure upon the third nerve and suggested that from some obscure cause there might be pressure upon the medulla.

Dr. TRACY said that he had wondered if it could be that at times there was an increase in cerebro-spinal fluid, which pressed upon the sympathetic. He had thought of intestinal toxemia as a possible cause. There are passed in the urine in twenty-four hours an average of 800 grains of solids, which for a woman of her size is not abnormal.

PRACTICAL URETHROSCOPY WITH THE EXHIBITION OF A NEW INSTRUMENT.

Read before the Mississippi Valley Medical Association at Louisville, Ky., Oct. 5, 1897.

BY EUGENE CARSON HAY, M.D.

President Garland County Medical Society; Member Arkansas Medical Society, American Medical Association, Mississippi Valley Medical Association; Fellow of the American Academy of Medicine.

HOT SPRINGS, ARK.

Urethroscopy has been practiced, by a few of our profession, since the first attempt to inspect the urethra was made by Bozzini of Frankfort at the beginning of this century, but it was not placed on a truly scientific basis until Desormeaux invented his instrument in 1853, and named it the endoscope. It was far from perfect, and since then many different varieties have been invented, some with the light reflected from without, and others with it placed within the tube.

It is not my object to discuss the merits of all these different instruments. I will briefly mention two, but at best they are all far from satisfactory in the hands of most of us, and this is the true reason I believe why the endoscope has not been more generally adopted by the profession as a method of examination and treatment of all chronic urethral troubles.

The Otis instrument, using the Klotz tube with a small electric light incased in a diminutive condenser,

and this attached by a foot to the proximal end of the tube, is the one generally recommended by authors. This instrument has not proved satisfactory in my hands, and of recent years I have used nothing but an ordinary head mirror with reflected light; but the illumination secured was not always sufficient, and from this or my lack of expertness in manipulation, I was not able to obtain a uniform intensity of light until I adopted my present method.

Dr. Wassidlo of Berlin, in an article entitled "Practical Urethroscopy," published in the *Medical Record*, Sept. 7, 1895, gives a full description of the "Nitze-Oberlaender" urethroscope. But this is a very complicated affair aside from being an expensive instrument, which limits its use and general utility. I will give but a casual description of this instrument, and refer you to "Sajous' Annual of Universal Medical Sciences," 1896, Vol. 3, section E, page 18, where will be found a full description of the instrument and an abstract of Dr. Wassidlo's paper. In the "Nitze-Oberlaender" instrument, the light is applied within the tube by a platinum wire rendered incandescent by a galvanic current, and this is kept cool, to prevent burning the urethra, by a tunneled bar beneath, through which cold water circulates.

There seems several objections to this ingenious apparatus: 1. The tunnel through which the water circulates must be almost a capillary tube and I should think would become very easily clogged, and should such an accident occur while operating the result would be quite a severe burning of the urethral mucous surface. 2. I can not see how applications of nitrate of silver or any other liquid can be easily applied to the urethra without materially reducing or extinguishing the light; the same would result when operating through the tube if hemorrhage was produced. 3. The light carrier, lying in the bottom of the tube, must occupy some space, and when examining or operating through such a small aperture one wants a clear field and all the space is valuable.

Ocular examination of the urethra, in addition to the other methods now in use, is the only accurate manner by which we can arrive at a positive diagnosis in all old urethral troubles. Even after the microscope had been called to our assistance, I do not consider any examination complete until the urethroscope has been used. The endoscope is equally as indispensable to the genito-urinary surgeon as the ophthalmoscope and laryngoscope are to the eye and throat specialist.

An instrument that will simplify the procedure, is simple and easy to manipulate, always ready for use, not easy to get out of repair and illuminates the urethra perfectly, will commend itself to all, and cause endoscopy to be more universally adopted by the profession, as a most valuable accessory in the examination and treatment of that class of genito-urinary diseases to which it is adapted.

Last spring, while experimenting with an ordinary Mackenzie condenser with head mirror attached, which I used on a student lamp, I discovered that by placing the lamp by the side of my operating table, close to the patient's thigh, then inserting the endoscope and adjusting the mirror to properly focus the reflected light into the tube, that by placing my head behind (but close to) the mirror and looking through the small orifice in the center, with the left eye, keeping both eyes open as one does (or should do) in the use of the microscope, I secured a most excellent

illumination of the urethra; by far better than I had ever been able to obtain when the mirror was attached to my head. I also discovered that it greatly simplified the work, for when I turned to pick up an applicator to sponge the mucous membrane or make a topical application, I rarely lost my focus, and when I did, it required but an instant to secure it again. This led me to devise the instrument I present here.

The method of procedure in manipulating my apparatus is as follows: After placing the patient in proper position on your operating table or chair, the lamp stand is set close to the corner of the operating table and then the lamp is adjusted to a proper elevation and secured by a thumbscrew. The thumbscrews are then loosened for the transverse adjustment and the lamp is placed immediately over or close to the patient's left thigh. The endoscope is then

uated at the end of the fossa navicularis." In the cavernous and bulbous portion the urethra is relatively wide and in most cases will accommodate as high as No. 30 to 32, French scale, but a tube No. 28 French is the size that I most generally use. I use a plain straight tube, five inches long, for examining both the anterior and posterior urethra, and with the illumination I secure, do not find it necessary to use the three-inch tubes, as recommended by Dr. Klotz, for work in the anterior urethra. Since using Dr. Oberlaender's jointed obturator for introducing a straight tube into the deep urethra (making it assume the form of a Mercier catheter) I find it renders it a much simpler operation and materially reduces the pain for the patient.

When examining the anterior urethra with my instrument, I place the patient in a semi-recumbent

FIG. 1.—Front view of urethral illuminator.

FIG. 2.—Side view of urethral illuminator.

inserted and the operator takes his seat between the patient's thighs before withdrawing the obturator from the tube. The obturator is then withdrawn and the mirror focused to properly throw the reflected light into the tube as previously described, the operator looking from behind the mirror, through the small circular orifice in the center. The endoscopes I use are thin metal tubes, Otis pattern, and I prefer them to Klotz's. I always use as large size as possible, as recommended by Oberlaender and Kollmann, as they state "that the lining membrane being longitudinally folded, it is desirable that these folds be smoothed out during examination, and this requires large-sized tubes. The only difficulty in introducing large tubes may be experienced at the external orifice or at the valve of Guérin, which, when present, is sit-

position, in fact almost sitting upright, knees flexed, and draw the nates as near the end of table as possible.

When examining the deep urethra the position is the same, with the exception of having the patient lie perfectly prone. I then insert the endoscope and when withdrawing it bring the tube out parallel with the patient's thighs instead of following the arc of the natural urethral curve, as instructed by authors; and I have never found it any more painful. To pass a straight tube into the deep urethra and retain it there, is a painful operation unless the urethra is thoroughly anesthetized, and when this is done the cocaine produces such profound anemia of the mucous membrane that your pathologic picture is materially changed.

In conclusion, the advantages I claim for this instrument are simplicity, ease of manipulation,

excellent illumination of the urethra and general utility for the general practitioner, because it can be used to illuminate the nose, throat, ear, rectum or vagina, and it is a superior apparatus for use with the Kelly's proctoscope and sigmoidoscope or for catheterizing the female ureters, Kelly's method.

In large cities where the electric current can be secured during the day, an electric light or gas can be used, having the apparatus supported by an universal bracket and attached to the wall, which would dispense with the uncleanness of oil and make the instrument much lighter.

I do not claim any originality in devising this instrument except this particular method of applying the light and illuminating the urethra.

EPILEPSY AND ERYSIPELAS.

BY ROBERT HESSLER, A.M., M.D.

Pathologist to the Central Indiana Hospital for Insane; Recently Physician at the Northern Indiana Hospital for Insane; Formerly Demonstrator of Pathology, Medical College of Indiana, and Pathologist to the Indianapolis City Hospital.
INDIANAPOLIS, IND.

"The disease known as epilepsy is probably the most disheartening condition as to treatment that the physician has to deal with, since it often resists the influences of all standard remedies, and drives the practitioner from drug to drug in the hope of finding one which will be at least alleviating in its effects."—(Hare, "Practical Therapeutics," p. 496.)

Soon after beginning service in the Northern Indiana Hospital for Insane, in the summer of 1894, I began to make a careful, systematic study of the male epileptics with a view of ameliorating their condition as much as possible. Among the 300 males in the hospital there are always present from 30 to 35 epileptics, changes being comparatively few. All are well marked cases and exhibiting every grade of mental decay. Simple cases with few convulsions and without decided mental change are not admitted to the hospital.

Syphilitic, toxic and apoplectic convulsion cases are not included in this paper; cases accounted for are what may be called, for convenience, "idiopathic epileptics."

A careful clinical record was kept of all cases. Among the remedies tried were potassium bromid, sodium bromid, strontium bromid, opium, acetanilid, solanum carolinense and sodium salicylate. Some of these were used for weeks and others for months at a time. The results obtained were not of a kind to encourage one's belief in the efficacy of medication.

Potassium bromid must be placed at the head of the list. In suitable doses it has a beneficial influence in many cases; some are little affected by it, while in others the convulsions are controlled for a time only and then they recur with increased frequency, and in the course of a few days make up the usual monthly average. Its congener, sodium bromid, does not differ materially from it. Strontium bromid is less apt to bring on an irritable or even maniacal state of mind, a condition noticed at times, in certain cases, with potassium bromid. The largest continued amount given per day was 7.8 grams.

Opium, with and without potassium bromid, was tried in several cases; the results were not very marked. Solanum Carolinense, in various sized doses, was tried in three cases and after several months discontinued; it has little or no influence on convulsions in chronic cases. One epileptic dement became very active and maniacal under its influence but subsided

promptly on returning to potassium bromid. Acetanilid was tried, and in one case 0.32 gram was given after each meal for a number of months without any results whatever. Sodium salicylate was given to three cases for several months, beginning with 0.97 gram after meals and increasing to 1.3 grams, no effects noticed. Salicylates are reported to aggravate convulsions, but certainly did not do so in my cases.

After keeping up my observations for a year without noting marked beneficial results from any form of treatment, I finally adopted a routine treatment for all chronic cases that bear bromids well, 3.9 to 7.8 grams of potassium bromid being given every day for a week or two, alternating with a solution of sodium chlorid for the same length of time. Many epileptics are constantly asking for medicine and live in hope while getting it, their faith in medication being unbounded. Laxatives were given whenever indicated.

While these observations were going on, one case had a singular termination. An epileptic aged 46, who had from forty-five to seventy convulsions per month, under any and all kinds of treatment, was attacked by erysipelas, toward the close of 1894, involving the face and neck. The temperature went up to 104, with delirium at the crisis. The disease ran the usual course and the patient recovered promptly. After this the convulsions practically ceased. The very few that occurred thereafter were light, *petit mal*. There was no mental disturbance as formerly, and the patient believed that he was well, and no longer was in dread of an oncoming convulsion.

During the year 1895 I often pondered on this remarkable change and at times even wished for more erysipelas among the epileptics. To inoculate the disease was, of course, out of the question; the frequently fatal termination of erysipelas forbade such a procedure. Then this thought occurred: Will the toxic products developed by the growth, by the artificial culture, of the streptococcus pyogenes (*S. erysipelatus*) produce a similar result when injected hypodermically? After much hesitancy I proposed a test to the medical superintendent and he readily agreed to a trial. A preparation of erysipelas antitoxin was obtained and used with gratifying results.

The patient receiving the preparation, or remedy, was a chronic epileptic, a hopeless case in the light of all previous medication, considerably demented, simple and childish, age 25, weight about 140, always tractable and never violent. Convulsion varied from one to four a day in number, or from twenty-four to fifty-two per month, under any and all kinds of treatment. Recently he had an attack of status epilepticus. Observations on the pulse, temperature and respiration were made for two weeks prior to treatment and then a preliminary hypodermic injection of normal salt solution was given, merely to see how he would bear hypodermics. March 19, 1896, the first dose of the antitoxin, or toxin, was given 3 c.c. in the arm. No local or systemic disturbance followed and two days later 5 c.c. more was given. No reaction was noticed and the dose was gradually increased, at intervals of a few days, up to 10 c.c. After about 45 c.c., or two ounces, had been given a marked diminution in the number of convulsions occurred and *petit mal* at times took the place of the customary *grand mal*, something not seen before, and the patient said that he could feel the attacks coming on and "could fight them off" at times. The longest period without convulsions was twenty days. The mental condition

improved, and the patient became brighter, more active and very hopeful. The injections were almost painless. No other treatment was given during this time and bromids had been discontinued some time before.

The following table shows the number of convulsions, the amount of toxin given, and dates:

	C.c. toxin injected.	Convulsions per month.
Previous to March, 1896, an average of about		45
March, from the 19th to 23d	18	
April, from 2d to 8th	27	
April		8 ¹
May	0	
May		3
June, one dose on the 15th	8	
June		2
July, 8 c.c. on the 15th; 9 c.c. on the 23d	17	
July		8
No toxin after July 23.		
August	0	16
September	0	26 ²
October	0	28
November	0	33
December	0	53

Patient put on potassium bromid from December on.

The remarkable result obtained induced me, in April 1896, to try this remedy in other cases, but, only a very small quantity of the antitoxin could be obtained. The only use for this agent, it seems, had been in the experimental treatment of malignant tumors and cancers, and the supply on the market was very limited. After considerable delay a specially prepared supply was obtained and given to several patients, these being all considerably demented, and with an extremely unfavorable prognosis, in fact they were to be regarded as hopeless cases when viewed in the light of all previous attempts toward relief. The preparation used was the clear serum of a sheep which had been previously injected with a virulent culture of the erysipelas streptococcus, the method of preparation being that of Emmerich and Scholl. In this paper I have used the terms antitoxin and toxin synonymously: I do not know which should properly have the preference.

The next, or second patient to receive the injections was a man, almost six feet high and weighing about 180 pounds, age 36, who has had epilepsy for the past ten years; is deteriorating rapidly. Convulsions, all severe, varied from twenty-five to fifty-four per month while under my observation and were steadily increasing in number, even under large continued doses of potassium bromid. Injections were begun toward the middle of April 1896, and continued with intervals of a few days. I can not give the exact figures in this case, because my clinical chart for the month of May is missing. Convulsions continued with exasperating regularity and frequency for the next two months and then a decided change took place. The attacks became mild in character, and in July, a marked diminution in number took place; he would now miss an occasional day. After July 17, no toxin was given and soon thereafter the convulsions returned with their usual frequency and severity. He had thirty-five convulsions, mostly *petit* during July, and thirty-one during August. The number increased to fifty in September, and to sixty-eight in October

and he was again placed on potassium bromid. The condition of the patient now was essentially as at the time prior to this treatment.

A man aged 20, in excellent bodily condition, has had epilepsy for the past five or six years, gradually growing worse, maniacal at times. This patient also improved, that is, the convulsions diminished in number and severity while under the influence of the remedy. After it was discontinued he gradually returned to his former condition.

A man aged 28, in fair physical condition, has had epilepsy for seven years, slightly disturbed at times, usually quiet and sensible, reported to have had from one to four convulsions per day while at home. He was greatly benefited by a course of bromids, but the convulsions would promptly return, and with increased frequency, on withholding the remedy for a week or so.

This patient had heard of the good results obtained with the new medicine and was very anxious to be given a trial. The remarkable inhibitory effects of the toxin were again shown in this case, in fact the patient improved so much that he went home on furlough and was ultimately discharged from the hospital: I do not know his history thereafter. The only incident out of the usual in the whole series of injections occurred in this case. While giving a large injection the lump raised by the fluid beneath the skin of the left arm suddenly disappeared and at the same time a general erythema, or reddening of the whole body appeared and he said he felt "queer" for a few moments. Evidently the toxin had suddenly found its way into the general circulation and brought on this disturbance: the effects passed off in a few minutes.

My experiments at the time were limited on account of the difficulty of obtaining a proper and sufficient supply of toxin and because it was an expensive remedy. All injections were made under strict aseptic precautions; the syringe was always washed out with boiling hot water before use and all air was excluded in filling it. There was not a trace of inflammation at the site of any of the numerous injections. The pulse, temperature and respiration at no time showed any variation from the normal, that is, a normal epileptic. A careful clinical record was kept. All of these patients were under close and constant observation by the attendants. No evil results followed the injections, and the beneficial effects are certainly remarkable. It should be borne in mind that my cases were all well advanced epileptics, and perhaps excepting the last one mentioned, not amenable to the ordinary methods of treatment; the usual remedies, like the bromids, had little influence on them. In my opinion, the old observation that all new methods of treatment have a temporary beneficial effect does not apply in the cases reported here, because decided results appeared only after repeated injections had been made, after the body had been saturated. Moreover, the time element is too great; such effects, due to mental influences, do not usually extend over a period of a few days, and in the case of chronic epileptics are scarcely noticeable. I have no doubts whatever concerning the beneficial effects resulting from the attack of erysipelas in the first case mentioned, and the results obtained by the method given are certainly very gratifying. No positive conclusions can be drawn from so few cases; observations must be repeatedly verified. The remedy may possibly be of still greater utility in recent or acute cases,

¹ Several of this number being attacks of *petit mal*, heretofore all had been *grand mal*.

² In addition to these *grand mal* attacks, many *petit* appeared during September, October and November, but practically ceased by December; the convulsions from this on being of the former *grand mal* type, the modifying effects of the toxin having disappeared completely.

cases in which the epileptic habit is not fixed. My cases offered the least hope for a recovery on account of their long duration.

The pathology of epilepsy, especially when not traumatic, is very obscure, and so little is known of the products developed in the animal body by the growth of the erysipelas germ, that the subject of the relationship between epilepsy and erysipelas naturally becomes complex, and all facts and details must be worked out experimentally.

Recently, while in the library of the Surgeon-General of the United States Army at Washington, I was greatly surprised to find that there was no literature on the treatment of epilepsy by erysipelas antitoxin, and this fact leads me to publish these notes, though so long a time has elapsed since the observations were made.

Serum, toxin and antitoxin therapy is still in its infancy, and no one, it seems to me, can deny the efficacy if not as a cure, at least as a palliative measure of such a method of treatment, without first giving it a thorough trial. The results obtained so far, as given above, certainly justify a more extended application of this method of treatment for one of the most intractable of diseases.

SEROUS INFLAMMATION.

Read before the Milwaukee Medical Society, Nov. 9, 1897.

BY W. H. WASHBURN, M.D.

Professor of Principles and Practice of Medicine and of Clinical Medicine in the Wisconsin College of Physicians and Surgeons;

Physician to the Presbyterian and Johnston
Emergency Hospitals, etc.

MILWAUKEE, WIS.

According to the biologic theory inflammation, in its ultimate analysis, "is the reaction of phagocytes against a harmful agent." This theory, which Metchnikoff has done much to establish on a scientific basis, bids fair to be universally adopted by scientists within the next few years. Wherever there is phagocytosis there is inflammation and without phagocytosis there is no inflammation. In its most typical form inflammation presents well recognized features: redness, heat, pain and swelling, but viewed from our present standpoint, none of these features are essential or necessary parts of the inflammatory process. They are merely more or less frequent accompaniments of the essential feature, the reaction of the phagocytes, either local or mobile, or vascular, against some irritant. That inflammation may exist in the absence of preternatural heat is proven by the occurrence of the process in the cold-blooded animals; that it may exist in the absence of redness and swelling is proven by its occurrence in such invertebrates as are destitute of vascular system, and that it may be present and not occasion pain is indicated by its occurrence in animals that are devoid of a nervous system, as the spongiae and acalyphæ (the medusæ, hydrozoa, etc.).

In all inflammation, then, the essential and necessary thing is the reaction of the phagocytes against an irritant, generally chemic in character. In proportion to the virulence of the irritant and its amount will the inflammatory reaction be active or otherwise, but when the irritant is of overwhelming virulence no reaction on the part of the phagocytes may be possible and death from general sepsis rapidly ensues, as in the case of experimental inoculation of guinea pigs with the vibrio Metchnikowii, of rabbits with the cocco-bacillus of hog cholera, or when rabbits are

inoculated with microbes of very malignant chicken cholera. Here death ensues within a few hours without any phagocytic reaction and therefore without inflammation.

Some of the best known authorities on pathology have opposed the biologic theory of inflammation very vigorously, and many have found in serous inflammations a stumbling block to the acceptance of the theory. It is the purpose of this paper to attempt to show that serous inflammation is a process differing only in minor respects from the best known and typical inflammation, such as is seen in the development of a phlegmon and which process is attended by the accumulation of pus in an abscess cavity.

I speak now of the inflammations of the serous membranes, in which the exudate is serum with a very few cells, and not of what might technically be regarded as a purely serous inflammation such as show an entire absence of cells, if such ever does exist.

The irritant whose presence in the tissues occasions the phagocytic reaction which constitutes inflammation, may be of any grade of virulence, from the mildest to the most severe and rapidly fatal, and accordingly, we encounter the inflammatory process in all grades of severity, from that painless variety which results in the repair of trivial wounds to most virulent peritonitis due to septic infection. The inflammation-producing irritant, chemic in nature, may be of either organic or inorganic origin, that of organic commonly giving rise to the most violent phagocytic reaction.

In cases in which the irritant is of inorganic origin and a definite and moderate amount of the irritant is introduced into the tissues, the same is rapidly taken up, destroyed, carried away and eliminated by the phagocytes, or becomes encysted, the local disturbance subsides and we say that the inflammatory process has terminated by resolution. The same termination is also frequently observed where the irritant is certainly of organic origin, as in the resolution of inflamed lymphatic glands occurring in the course of scarlatina or diphtheria. I call your attention to one more common accompaniment of the process under consideration, the swelling.

In the most primitive form of inflammation the mobile tissue cells alone take part in the process. When the process is more complete the endothelial cells of the blood vessels react, contracting in such a manner as to allow of diapedesis, and at the same time permitting the escape of the fluid portion of the blood into the adjacent tissues. The swelling, therefore, in typical acute phlegmon is due in part to the escape of the blood serum and cells into the tissues and lymph spaces in the parts immediately adjacent to the localized irritant.

It frequently happens that the swelling extends to a considerable distance beyond the localized seat of the irritant. For example, a case recently under treatment presented a localized infection at the inner border of the nail of the great toe with active inflammation in the parts immediately adjacent. The dorsum of the foot was considerably reddened, painful and swollen, so much so as to suggest the existence of erysipelas. Beyond this and up the ankle, two or three inches above the inner malleolus, the parts were increased in size and pitted on pressure— inflammatory edema—the whole disturbance rapidly subsiding on incising and disinfecting the original site of the process.

Edema results from one of two things, there is either an increased transudation of blood serum into the subcutaneous lymph spaces, or, the transudation remaining the same, there is a lessened rapidity of absorption. It is more or less probable that in the case of inflammatory edema we may have a combination of the two.

The blood vessels being rendered abnormally pervious by the inflammatory process, there will, of necessity, occur an increased outflow into the lymph spaces, and in the case of inflammation of serous membranes the outflow will take place into the serous sac, itself an immense lymph space. In the ordinary course of events effusions into serous cavities are absorbed, in part by the lymphatics, and in part by the blood capillaries. That fluids are thus absorbed from serous cavities by the capillaries has been shown fairly conclusively by Orlow and Heidenhain, and facts tending in the same direction have been demonstrated experimentally by Kellgren and Colombo, whose work is quoted in the "American Year Book of Medicine and Surgery," for 1897.

In cases of serous inflammation, therefore, even supposing that the outflow of fluid is little if any increased there will be, in consequence of the condition of the blood vessels, lessened absorption and as a result accumulation of fluid in the serous sac.

The serous membranes, in general, are so situated as to be comparatively inaccessible to the ordinary inflammation-producing irritants. Inflammations of serous membranes are nearly always secondary affections, except when caused by traumatism. They are secondary to such diseases as tuberculosis, bronchitis, pneumonia, cancer, rheumatism, Bright's disease and gonorrhea.

Bacteriologic studies of pleuritic serum have shown the presence of various microbes, among others the tubercle bacillus, staphylococci, Eberth's bacillus, and various cocci of unknown species, but in the majority of cases of serous pleurisy bacteriologic studies have been negative, no micro-organisms of any kind being discoverable in the effused fluid. The fact that the fluid of serous inflammation was free from micro-organisms early attracted the attention of bacteriologists and it was theorized that the purpose of the serous effusion was the destruction of the germs which were believed to be the cause of the inflammatory process. The fact had been known for some time that the blood serum of certain animals possessed bactericidal properties, as for example that of the rat against the anthrax bacillus, and that of the vaccinated guinea pig against the vibrio Metchnikowii, at least, in test tube experiments. But that experiments of this kind are an insufficient basis for drawing conclusions has been shown by Buchner and others, the bactericidal properties of blood serum, which are so evident in test tube experiments, often failing to develop in the living body. Later experiments, moreover, have shown that many bacteria are able to live and multiply in the fluid of serous inflammation, and hence the purpose of the exudate can not be bactericidal.

Another theory then advanced, was that the purpose of the effusion was to neutralize toxins, in other words, that the serous effusions contained antitoxins. This theory was naturally suggested by the remarkable discovery of Behring and Kitasato in 1890, that the blood of certain immunized animals possessed antitoxic properties. Tizzoni and Cattani later showed

that the serum of rabbits immunized against tetanus is capable of destroying considerable quantities of the toxins of this disease.

The same results have been secured with respect to diphtheria, and the Klemperer brothers believe that they have proven that the blood serum of animals (rabbits), that have been immunized against pneumonia, and that of men who have recently recovered from pneumonia, possess antitoxic powers. This theory also appeared to be supported by the fact that Behring discovered diphtheritic toxins in the pleuritic effusion of rabbits suffering from diphtheria. The more closely, however, this point has been studied the more evident it has become that this view is untenable, there appearing no necessary connection between the production of antitoxins and the occurrence of serous effusion.

The pleura is a closed serous sac applied to, and in organic union with, the lung and costal parietes. Its internal surface is lined with endothelium, and in the cellular tissue subjacent, lymphatics are abundantly distributed, which, in the visceral portion, freely inosculate with the pulmonary lymphatics on the one hand, and on the other communicate by innumerable open mouths or stomata with the closed pleural sac. Within the subserous tissue the blood vessels form a wide meshed capillary reticulum over the whole surface of the lung, and these capillaries freely communicate with deeper vessels which originate in the interalveolar septa throughout the lung substance, and where ever there are fat sacs or lymphoid masses these are enclosed in capillary networks.

When we regard these anatomic conditions, in connection with the fact, that in case of infection in remote parts of the body the infectious materies may be brought, through the pulmonary and pleural capillaries, directly in contact with the visceral pleura before it is carried to other parts of the body, it will not seem strange that the pleura is very often the seat of acute inflammatory processes.

The fact that pleurisy is an extremely common affection is shown in the autopsy room, where it is comparatively rare to find perfectly normal pleura in adult cases. In a hundred autopsies, in adult cases, performed in the past three years, I have noted but eight in which there were no evidences that the deceased had at some time suffered from pleurisy. So common indeed are inflammations of this membrane that it has well been said, that it is the chosen site for the manifestations of lesions from blood contamination.

Pus germs, or their products, so frequently present in the bronchi, can readily gain access to this membrane. The products of the bacillus of tuberculosis are frequently brought to the same situation with resulting serous inflammation, there being entire absence of tubercle bacilli in the exudate. The fact that very many serous pleurisies are due to the products of the tubercle bacillus is established by records showing that nearly 40 per cent. of cases of serous pleurisy later develop the clinical features of pulmonary tuberculosis.

The pneumococcus and its products are frequently the cause of serous pleurisy, and the process in this instance is established in the same manner as in the previous case.

Serous inflammation, however, occurs also in connection with the peritoneum and the pericardium, but inflammations of these membranes are of much less frequent occurrence than are pleurisies. In their

histology these membranes are nearly identical with the pleura, their lymphatics originate in the same way, and they contain a capillary net work of blood vessels differing in no material respect from those already described in connection with the pleura. But these blood vessels are much further from the ordinary sources of blood contamination than are those of the pleura, and hence the comparative infrequency of inflammations of these membranes. The blood vessels of the pericardium are nearer to the sources of blood contamination than are those of the peritoneum, and pericarditis, as a consequence of blood contamination, is much more frequent than is peritonitis. But I think another explanation of the relative frequency with which these serous membranes are involved in the inflammatory process, except as a result of local causes, may be found in the relative time at which these structures have been developed in the progress of evolution.

It is a fairly well established fact that those organs and tissues of the body which have been latest developed in the progress of evolution from the lower forms of animal life to the higher, are those which are most frequently the seat of pathologic processes. The muscular system is the oldest and diseases of the muscles occur infrequently. The respiratory organs, being very lately developed, are comparatively often the seat of disease. A fair idea of comparative frequency with which diseases affect these two systems, the muscular and respiratory, may be derived from a comparison of the space required in which to discuss them in works on the practice of medicine. In the "Twentieth Century Practice of Medicine," the article on diseases of the muscular system covers but 44 pages, while 946 pages are required to deal with the diseases of the respiratory system.

An inquiry into the chronology of the development of the serous membranes under consideration shows that the peritoneum is the oldest, the pericardium next, and the pleura is the youngest. And we find that these membranes are endowed with the power of resistance of pathogenic influences such as would be indicated by their comparative ages, the peritoneum being most resistant, the pericardium next, and the pleura least of all. Serous inflammation of the peritoneum is a comparatively rare disease and is produced by very few irritants, the most common cause of serous peritonitis being the tubercle bacillus.

On the other hand, serous pericarditis may result from a much greater number of irritants, as for example, the materies of rheumatic fever, typhoid fever, pneumonia, by extension of the process from the pleura in cases of simple pleurisy, as a result of the infectious materies in various acute febrile diseases, and in connection with chronic Bright's disease and pulmonary tuberculosis.

Reverting now to what has been said as to the inflammatory process in general, the phagocytic reaction will be in direct proportion to the number and virulence of the micro-organisms present unless these are in such overwhelming numbers and of such virulence as to preclude all phagocytic reaction.

Carrying this idea into our inquiry as to the inflammatory product in cases of pleuritis we shall expect to find present in the exudate, cellular elements in direct proportion to the micro-organisms present as a cause of the process. And this expectation is verified by the result, the majority of pleuritis being secondary to other processes, and not involving the

localization of micro-organisms at the seat of the inflammatory reaction, we commonly find very few cells in the inflammatory exudate, but where the inflammation is due to the transfer of micro-organisms from some other situation in the body to the pleura, the process there set up is of a more acute character and the inflammatory product is rich in cells, in other words, we have purulent pleurisy.

In the first class of cases the irritant is readily seized upon, removed or destroyed by the phagocytes, this reaction being attended by a contraction of the endothelial cells of the blood vessels to an extent sufficient to allow of a certain amount of diapedesis, with accompanying transudation of serum, and at the same time a cessation of the absorbing function of the capillary blood vessels, with consequent accumulation of fluid in the pleural sac. This sac being regarded as a large lymph space we have a process here which differs in no material way from ordinary inflammatory edema.

It would then appear unnecessary to search for some obscure explanation for the peculiar character of the product of inflammation of serous membranes. When we bear in mind the histology of the pleura, its numerous and intercommunicating lymph channels opening into the pleural cavity through stomata and intervening canaliculi, its wide-meshed capillaries freely inosculating with those originating in the walls of the pulmonary alveoli, its vulnerability to irritant substances of either organic or inorganic origin, the fact that, when the seat of inflammation, its capillary blood vessels no longer act as absorbents, it would seem that this particular kind of inflammatory product ought to be expected in the great majority of cases.

And further, it would seem that the true explanation is as follows: That in inflammations caused by irritants other than micro-organisms a limited phagocytic reaction only is called for, and this reaction being accompanied by sufficient contraction of the endothelial cells of the capillary walls to admit of diapedesis a serous effusion follows; this serous effusion is coincident with a cessation of the functional activity of the pleural capillaries as absorbents, it being a self-evident proposition that capillaries that are pouring out serum will not at the same time act as absorbents. The result of this combination of circumstances is an accumulation of fluid in the cavity of the pleura; and this accumulation of fluid must be regarded as constituting no necessary part of the inflammatory process, but as a mere concomitant, and conditioned upon the anatomic and physiologic relations of the parts involved, the essential thing being the phagocytic reaction, which alone constitutes the inflammatory process.

726 Grand Ave.

Ultimate Results of Operations for Spina Bifida and Encephalocele at the Prague Children's Hospital since 1888: Without operation, death; with operation for encephalocele, 38 per cent. saved; for spina bifida, 41 per cent. saved. Of those that survived the latter operation, 59 per cent. died within a certain interval afterward. C. Bayer adds that a favorable result can only be expected of the operation when there is no hydrocephalus, paralysis nor defects in important regions of the central nervous system. He no longer operates if any of these are present. He covers the sewed up, reduced meningeal sac with a flap of fascia or muscle, periosteum on the skull, and consecutive skin flap suture.—*Cbl. f. Chir.*, April 2.

HYPERKINESIS OF THE MUSCLES OF MASTICATION A SYMPTOM AND AN ETIOLOGIC FACTOR IN NERVOUS AFFECTIONS

PARTICULARLY NEURALGIA OF THE TRIGEMINUS AND DISEASES OF THE JAW.

Presented in the Section on Stomatology, at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY GEORGE V. I. BROWN, D.D.S., M.D., C.M.

DULUTH, MINN.

Kinetic action or movement is recognized in contradistinction to trophic action, signifying growth and structural change, and indicates, in greater or less degree, an expenditure of nerve muscular action, implying also an expenditure of nerve force. This within the limit of natural involuntary muscular action implies a corresponding increase of trophic action conducive to the condition of health and development, but if the nerve stimulus be over excited or too long continued, whether by some exciting cause directly affecting portions of the brain or spinal cord, by a state of general excitement known as a nerve storm, excessive voluntary action, or in any other manner extreme muscular activity be induced, there is an arrest of structural development and thus trophic action ceases with a corresponding loss of vitality and substance. Having these simple facts in mind it is easy to understand why localized symptoms of brain lesion should be, as they are, evident in paralysis and spasm of the muscles supplied with motive force by the nerve centers affected by the lesion.

A diseased condition capable of producing a spasm may also produce paralysis and any abnormal muscular activity particularly confined to certain muscles or groups of muscles may be taken as an indication of some disturbance of nerve muscular action.

In discussing the symptomatology of nervous diseases writers make frequent mention of both tonic and clonic spasms of the masseter and pterygoid muscles as in tetanus, epilepsy, lunacy, chorea, etc., while tooth-grinding is a symptom noticed frequently in such nervous disorders as migraine, hysteria, tetany, neuralgia, neurasthenia, paralysis and neuritis, and though noticed as a symptom by several authorities, has not been given the full consideration that it deserves.

Tooth-grinding is produced, as we know, by the action of the deeply seated pterygoid muscles, champing of the jaws, or the intense unconscious pressure (so frequently disastrous) by the masseter and temporal muscles, all of which are supplied by the motor division of the fifth nerve, and it is to their condition that we must look for information as to the condition of the central origin of the nerve.

Warner tells us: "Tooth-grinding is noted as a symptom common among those who suffer from nervous disturbances, choreic and like affections."

In classifying the primary symptoms of fifty-eight cases of children of nervous mobile temperament, under 15 years of age, suffering from headache, Warner says: "We find the largest number referable to the mental and cerebral condition of the child. We are told that he is excitable, melancholy, passionate of temper. His sleep is restless and disturbed by dreams and night talking, by attacks of terror and night screaming, or by somnambulism." In studying this group of nervous, excitable children, in whom recurrent headache was the main symptom, it was first

necessary to look for certain objective signs by which they might be identified, and these were principally found in the condition of the nerve muscular system, the teeth and urine. In a large proportion of cases the teeth were found flattened on the edges as the result of tooth-grinding.

After describing in detail the various muscular conditions, he says further: "We may look for signs of irritation of the cranial nerves; evidence of disturbance of the fifth nerve is seen in the great frequency of tooth-grinding. Ground teeth are very common in nervous children, such as those who suffer from recurrent headaches, restless sleep, somnambulism and finger twitching. In lunatic asylums and wards for imbeciles it is very common to hear tooth-grinding on every side. In such cases it is a sign of central irritation of the fifth nerve. Seeing that slight nervous disturbances occurring during sleep in many children cause the pterygoids to contract rhythmically, it is not surprising that grave disease should cause spasm of the other muscles supplied by the fifth nerve as in epilepsy and hysteria."

H. L. Ranney ("Lectures on Nervous Diseases," p. 406), describing symptoms of chorea, says speech, mastication and swallowing may be seriously embarrassed; even the teeth have been known to be broken by uncontrolled movements of the jaw.

Dr. Herman, Hughlings Jackson and others also call attention to this, in a similar manner, as a symptom of these diseases, but I am assured that the widespread influence of the action of these muscles, not only as a symptom, but as a factor in disease, is by no means appreciated, either by physicians or dentists, to whom we might naturally look for its more frequent mention.

We note in the references quoted that the tooth-grinding and the actions of the muscles of mastication are considered as symptoms of some general or central nervous condition, without apparent reference to the fact that such action might be, and frequently is, an active factor in the development of many pathologic conditions arising from irritation of the fifth nerve and its associates.

It is a common thing whenever people can be seen in moments of abstraction or deep thought, to see the lines of the masseter muscles, and also of the temporal, coming into prominence, as force is applied, disappearing and reappearing as the action is repeated, perhaps for hours at a time. And such a frequent occurrence is it to note this habit that it passes almost without significance, whereas such a freak on the part of any other portion of the body would be at once set down to some pathologic disturbance of greater or less nervous importance.

In my practice as a dentist it has become known to me through years of puzzling experience that the continuance of this effort at night, sometimes accompanied by a gritting sound as the crowns of the teeth are ground upon each other by action of the pterygoid muscles or, as more frequently happens, held forcibly together under severe pressure by action of the masseter and temporal muscles, without sound, which accounts for many cases in which the cause of trouble has remained undiscovered for a long period of time, is a frequent cause of reflex irritation.

The movement of the jaw in man, by reason of the freedom allowed at the point of articulation in the glenoid cavity, differs from that of the lower animals in its capability, not only of the perpendicular move-

ment accomplished in opening and closing, but of lateral, transverse and antero-posterior action as well.

The occlusal surfaces of the teeth when brought together in the normal arch are so arranged that each tooth from the lower jaw fits exactly inside and between the cusps of its antagonist in the upper jaw in such a manner that the application of force by the muscles is distributed among the whole number of teeth with comparative equality, save when engaged in the act of crushing and mastication. This muscular force, according to Black, is about three hundred pounds in civilized man, though probably much greater among the savage races unused to modern methods of preparing food, but if by reason of malformation of the jaw, or failure of perfect adjustment, or through slight shifting of its position in closing, the tips of one or two teeth are brought together instead of the whole number, naturally the effect of the force applied is many times greater than it should be, so that when constantly repeated as in nervous habit or spasmodic contraction (and it would seem not unlikely that under these conditions much more than the three hundred pounds allowed in voluntary action might be applied) through traumatism caused by a blow on the jaw, or in some other manner a like result be accomplished, it is at once evident how naturally injury must result to the extremely delicately organized peridental membrane surrounding the root, and the communicating artery, vein and nerve as they pass from the pulp, within the tooth, to join the main branch of the nerve supply, either or both of which frequently cause pathologic conditions of a grave character.

The peridental membrane has great power of resistance and recuperation, but the continued repetition of such undue force must set up an inflammation capable of effecting some pathologic change in the highly vascular and neural structure with which it is associated.

The first effect is naturally increased blood supply, and the bony walls allowing no expansion as the vessels become enlarged, the roots, being conical in form, widening from the apex to neck, are pushed a little out of the socket; thus an aggravating symptom is at once the result, since the crown of the tooth is raised a little above its fellows and liability to constant irritation is assured.

In the acute form of pericementitis usually the soreness compels notice and forbids biting, owing to its painful tenderness; while the rest thus enforced enables nature to effect recovery, unless the inflammatory condition be the result of too active irritation, as from the pulp chamber, in which case it may continue to the consummation of an alveolar abscess. In the subacute variety, as in other like affections, the symptoms are less severe and may proceed to recovery or become chronic. The chronic form may present little or no pain upon percussion or pressure, but at the same time may be a painful source of reflex disturbance; may cause exostoses or degenerative conditions favorable to, if not indeed a common cause of, pyorrhea alveolaris, and so cause the destruction of the membrane. Thus excitement of undue kinetic action of the muscles of mastication may be considered not only as an indication of some disorder of the nerve mechanism, with perhaps tendency to grave trouble, but may actively cause not only reflex pain in the form of distressful headaches, neuralgia, hyperesthesia, anesthesia, and other affections of sensation, but

motor troubles as well, and is of important consideration in cases of epilepsy, chorea, and various other neuroses, in diseased conditions of the peridental membrane, death of tooth pulps, alveolar abscess, secondary formations within the pulp chamber, empyema of the maxillary sinus and secondary affections of the eye, ear, nose, throat and stomach.

In order to impress the fact that the foregoing is not mere theoretical deduction and to call attention to the clinical aspect of the subject, I describe the following cases.

Case 1.—History of pain almost continuously for about two years, excruciating at times, particularly at night, less severe at other periods, extending over right side of face, forehead and region of the occiput; hyperesthesia so great that the face had not been washed for months; slightest touch to the surface of lower lip and cheek would cause intense agony. Teeth were all particularly good: no evidence of caries; arch regular, no apparent sensation to heat or cold applied to teeth: there was a slight dulness of sound upon percussion of right superior of first bicuspid.

Upon extracting and epilting the root the pulp chamber was found filled with calcareous degeneration of pulp tissue and pulp nodules. Immediately upon its removal all hyperesthesia left the face while the patient was still in the chair. The pain in the head was much relieved, but not cured. A further history of the case with more recent reports, would seem to indicate that being a typical neurotic, and having had what were termed by herself "fits" some years before, the force applied to the affected teeth during and since the epasme, as a result of this condition during paroxysms of pain, had produced the pulp degeneration, which, while evidently accountable for the facial hyperesthesia and much of the pain, was really secondary to a deranged condition of some central nerve, in conjunction with other motor nerves, and by reason of the undue force applied to the particular tooth affected had caused irritation, leading to the formation of pulp nodules and calcareous degeneration.

Case 2.—Mrs. S.; had one child with cleft palate. Suffered pain since 8 years old, supraorbital, paroxysmal, intense; teeth sound; no evidence of caries; on percussion right superior second bicuspid gave a duller sound than its fellows in the jaw; was not sore to touch, but was intensely sensitive to thermal changes.

Upon extraction the tooth was decalcified, and upon making microscopic sections minute growths were found along the inside of the pulp canal in the form of spicula, extending into the pulp substance, and though the pain suffered was evidently of an epileptic nature, probably the result of a fall in early life, these growths must have added to the suffering and were undoubtedly the result of irritation from the intense pressure during the paroxysms.

Case 3.—Miss , 17 years old, a typical neurotic; high contracted vault, irregular teeth with the usual accompanying symptoms of adenoid growths, catarrh, etc.

History of almost continuous pain for a period of two years; sometimes on one side of the face and head, sometimes on the other, occasionally bi lateral, and varying in intensity at different periods.

The pulps of seven teeth in both jaws were evidently hyperemic, and extremely sensitive to thermal changes where large amalgam fillings seemed to have excited undue irritation: the pulps were devitalized, an extremely painful process, only relieved by grinding down the crown of each tooth so that it could not touch its antagonist when the jaws were closed. This was the only thing that was found to give relief, and one after another the crowns of the affected teeth were ground down so that they could not strike in occlusion. This would give freedom from pain for a number of months, and upon the return of pain some tooth would be found slightly elongated. Again grinding would relieve for another period. It is of interest to note that when this patient became overtired, particularly with social efforts, she would frequently awake in the morning after a night of disturbed rest, with a sense of numbness in the teeth and jaws, due undoubtedly to severe pressure, or would be awakened by the return of severe pain.

About the beginning of the trouble she had become engaged to be married; the engagement was afterward broken. Another young man was then affianced to her: this was also terminated, and during this interval of several months, but little or no trouble was experienced. Recently, however, the third engagement was coincident with return of the trouble, and it was disclosed that after spending an evening in the young man's

company much difficulty was experienced in going to sleep. Therefore, our conclusions are that in this case the motor branch of the fifth nerve was excited in sympathy with sexual excitement; pressure upon the individual teeth was intensified by irregularity in the conformation of the arch, and this irritation was communicated to the sensory portion of the same nerve, with the usual painful result. Instead of grinding I have for some time past tied a piece of rubber dam, over the crown of one of the unaffected teeth so that the jaws can not be brought tightly together. Relief is complete after a few hours, or if applied in the night, next morning the rubber can be removed and the difficulty is completely averted for the time.

Case 4. Mr. —, much annoyed with slight tinnitus aurium on left side. No evidence of local oral or Eustachian trouble, as testified to by several aurists. Teeth much abraded. Has been much relieved by treatment and grinding off crown surfaces of several teeth.

An occasional slight return of his aural trouble is generally relieved by removal of some occluding portion of the left superior central incisor, which seems to be particularly in sympathy with the ear at this time.

Case 5. I have under my care at present a woman of about 40, whose incisors are worn almost beyond recognition; tendency to intense mental excitement upon slight provocation, particularly on subjects of politics, dress reform, etc., exists. She suffers from a difficulty of the right inferior extremity, threatening at times loss of sensation and motion.

After typhoid fever or other unusual drain upon the natural forces there seems to be a tendency to develop this habit of the jaws, and in many instances pain in the head and face had been relieved in my practice, by removing the possibility of continued irritation in the manner before described.

The fact that there is seldom soreness on percussion of such teeth, makes diagnosis frequently difficult and doubtless accounts largely for its not having been considered, as it should have been, as a diagnostic indication, but the surfaces of fillings, abraded crowns of teeth, or a dulness of sound on tapping with a metallic instrument will often serve to indicate in the absence of other and more marked symptoms of peridental inflammation.

A frequent complication from this habit, is pyorrhea alveolaris for which condition I have over and over again relieved the discharge about the necks of teeth and have hastened the retightening process of those loose in their sockets, by grinding them down to relieve unusual force in occlusion; its very common association with tenderness and pain following the process of devitalization of pulps, should make its consideration far more frequent than has hitherto been the case. Therefore, in the field of medicine, as a symptom of some neural disturbance of kinetic function or the direct excitant of some pathologic condition, the study of any abnormal activity of the muscles of the jaw is without doubt of far greater importance than is generally realized.

THE LIMITATIONS OF SERUM THERAPY.

BY JOHN MADDEN, M.D.

MILWAUKEE, WIS.

A review of the literature of serum therapy of the last two years is likely to produce some confusion. In the light of what has already been shown to be true, much elaborate experimentation seems to have been purposeless and final failure might have been foretold at the beginning. One of the prime causes of much misunderstanding is the failure to discriminate between the production of immunity from a disease and the production of resistance against a disease toxin. There is a wide difference between the two processes and the probable manner by which they are

brought about. In the former some change, the nature of which is not understood, has been produced which makes the body unfit as a culture medium for the growth of a particular bacterium and the consequent development of its special toxin. Ten years ago Buchner showed this substance to be an albuminous body which could be removed from the blood serum by dialyzation, and that it is the product of some unknown chemic reaction brought about by bacterial growth.

More recent investigations tend to show that a bactericidal substance resides in the granular matter of the leucocytes (Kanthock and Horry, Philadelphia Transactions, clxxxv. 1894; Vaughan and Novy, "Pto-maines and Leucomaines," 1896; Hankin, *Centralb. für Bakteriologie*, xii. and Mueller of Vienna, *Centralb. f. Allg., Pathologie und Patholog. Anatomie*, viii. 1896), and that these granules leave the white corpuscles and float free in the blood stream where they have the power of lessening the vitality of bacteria or destroying them altogether. In inflammatory diseases, such as pneumonia, pleurisy, rheumatism and erysipelas, there are an increased number of white corpuscles in the blood stream as well as a marked increase in the fibrinogen and serum-globulin (Halliburton, "Chemical Physiology and Pathology," pp. 306-7). It might therefore be assumed that here is an indication of disease producing its own antitoxin, and that when a sufficient number of white corpuscles are produced to destroy the invading bacteria the disease shall cease.

The problem, however, is by no means as simple as this. If the immunization or cure of a bacterial disease depended alone upon the mustering of an army of leucocytes sufficiently large to overcome and destroy the invading germs, then we should be able to show that the injection of anti-diphtheritic serum really increases the number of white corpuscles and that the subject is immune, not only from the Klebs-Loeffler bacillus but from invasion by all other bacilli as well. We should be able to show that vaccination with the kine pox permanently increases the number of leucocytes in the vaccinated subject and that he is rendered immune against all other bacteria forever.

As a matter of fact, however, when immunity is produced by an attack of bacterial disease or by inoculation in a modified form, that immunity is produced only against a subsequent attack of the same disease. It is clear, therefore, that the problem is a chemic one and that if the immunizing substance resides in the granular matter or is discharged from it, its chemic constituents must depend upon the disease against which the subject has been rendered immune.

If the chemic composition of the antitoxins thus produced were known as well as that of the toxins, the way would be paved for an exact knowledge of what might be expected as a result of applying antitoxin for the purpose of curing bacterial diseases; but so long as this remains unknown antitoxin therapy is liable to be more or less empiric.

It is well established that the changes produced in the blood serum by the development of an antitoxin is either for a time or permanently persistent. It also seems likely that the amount of antitoxin produced in each case is in direct ratio to the amount of toxin. This is well illustrated in vaccination with kine pox, in which the production of several well developed pustules attended with considerable febrile

reaction is usually followed by complete immunity against smallpox or against another vaccination. A very mild attack of scarlatina, measles, smallpox and some other eruptive fevers are sometimes followed by a second invasion. Furthermore, in such diseases as are followed by only temporary immunity against subsequent attack, the more severe the attack the longer the immunity if personal peculiarities are eliminated. If this be true, it may be concluded that the antitoxin results from a reaction between the toxin and some albuminous constituent of the blood serum, not that the toxin makes a definite chemico compound as if it were an acid radical and the serum constituent a base, but the toxin is responsible for bringing the change about.

Granted, then, that the antitoxin is produced, it may act in two ways to effect a cure, by making further bacterial growth impossible or by combining with and neutralizing the toxin as fast as it is produced, until the bacteria cease from lack of pabulum to be virile. Indeed, it may be that the cell protoplasm, constantly bathed in the antitoxin serum, is in some unknown manner changed so that the toxin contact is no longer harmful and is eliminated without disease symptoms.

The next question is: Do all bacterial diseases produce an antitoxin? It is reasonable to conclude that in the self-limited bacterial diseases like diphtheria, typhoid, yellow and other eruptive fevers, a peculiar substance is produced which gradually increases and is persistent in the serum and acts as a remedial agent in some way similar to that indicated above. Is this self-limitation due to the production of the antitoxin? When more is known of the bio-chemistry of bacterial diseases this question will probably be answered in the affirmative. A powerful argument in favor of this answer is that bacteria will develop as long as a suitable culture medium is offered for their growth. Those taken from an old culture medium, the pabulum in which is almost exhausted and which shows very little vitality, become virile when transplanted into a new and favorable culture medium. With the tissue changes constantly going on in the body, even in disease, the blood serum is tolerably constant in its chemico composition; so we may conclude that the self-limitation is not due to the exhaustion of the culture medium in the involved subject. To further support this view, the tubercle bacillus and other bacteria may lose their virility by exhausting the pabulum of an artificial culture medium, while in the body they are virile during the life of the invaded subject, the culture medium showing no change detrimental to their growth.

The question whether an antitoxin may be produced without the intervention of the bacterium is not definitely settled. In 1887 Salmon and Smith succeeded in rendering doves immune against hog cholera by injecting the artificial culture medium freed from bacilli by filtration. Many other similar experiments have been carried out; but what warrant is there for saying that this substance contains the toxin of the disease alone? In the absence of exact chemico knowledge it might be assumed that, even in an artificial culture medium, there are antitoxins as well as toxins generated, and that by injecting the exhausted culture medium, the subject received both the antitoxins and the toxins, retaining the former and eliminating the latter, as is done in the course of disease. Here the presence of an antitoxin might easily escape notice in the overwhelming

symptoms of poisoning produced by the toxin, if equal amounts were injected at the same time. Indeed, the antitoxin might be present in quantities much larger than the toxin, and, as far as its physiologic manifestations are concerned, entirely escape notice. As far as our knowledge is concerned all immunity produced by the injection of toxins may have been produced by the unnoticed antitoxins present.

We will now consider bacterial diseases which are not self-limited: tuberculosis, syphilis, leprosy and the like.

Do they produce an antitoxin? If so, why are they then not self-limited? There is no evidence that any of these diseases produce an antitoxin. The fact that they are not self-limited is a powerful argument against that hypothesis. If an antitoxin is produced by any of them, it is certainly different in all respects from that produced in the self-limited diseases, being insufficient in quantity, potency or persistency to produce any good result. When chemistry has mastered those complicated problems relating to the changes in the blood serum, produced by bacterial growth, we shall know why this is true, but for the present we must assume that the production of antitoxin in those diseases is an impossibility.

Certain animals are partly or wholly immune from particular bacterial diseases. The rat can not be inoculated with anthrax, the cow takes smallpox lightly and the horse is immune from tuberculosis. In some instances the blood serum of the immune animal will destroy the bacillus of the disease against which it possesses immunity, as in the case of the serum of the rat against the anthrax bacillus. In view of this fact, the question arises, whether the blood serum of an animal already naturally immune can be given greater bactericidal powers by injecting into the blood current the toxins of the disease against which it is immune? It can only be said that what evidence we have entirely supports the negative. The sheep and horse are both very susceptible to diphtheria and inoculation with the diphtheria bacillus produces a large amount of antitoxin. Shall we say that in exactly opposite conditions the same result would be had? Shall we say that the horse, immune against tuberculosis, a non-self-limited disease, will therefore yield a valuable anti-tubercular serum when injected with the toxins of tuberculosis? Certainly this is absurd: yet it is just what has been done during the last two or three years, by two or three men who have obtained considerable notoriety and profit. It certainly involves the heights of credulity to believe that the serum of an animal immune against a disease is rendered valuable, as a remedial agent for the same disease, by injecting it with the disease toxin without producing an antitoxin.

After the disastrous experience of a few years ago with Koch's tuberculin, it is not likely that any form or modification of the toxin, produced by the tubercle bacillus, will gain the confidence of the medical profession as a remedy for the disease. Tuberculin never did more than cause the breaking down of certain involved cell groups whose protoplasm was already surcharged with the poison. Under whatsoever modifications it may be used, it can never be of any value beyond an aid in making a diagnosis of tuberculosis.

As to the production of a resistance to a poison, that is quite a different matter from producing immunity, be the poison a disease toxin or something

else. Narcotic and other poisons may be taken in gradually increasing doses until an amount many times a poisonous dose, in the first instance, is readily tolerated. This means nothing more than that a resistance against that special form of poisoning has been established. Experiments of this kind have no value in serum therapy. It is quite likely that one might begin with a very small dose of some disease toxin, like that of tuberculosis or diphtheria, and by gradually increasing the amount exhibited, a resistance would be established which would make the injection of large quantities of the poison possible, but this is not immunity. The resistance would be speedily lost with the withdrawal of the poison, while a true immunity would persist for a longer or shorter time or permanently. The work of Calmette in establishing a resistance to snake poison is classed with serum therapy by some, but as a matter of fact it has nothing to do with serum therapy, unless it can be shown that these inoculations actually produce an antitoxin which renders the subject immune for a considerable time after the inoculations have ceased.

Referring again to the use of immunized horse serum for the treatment of tuberculosis and the favorable results reported, it is quite probable that all the benefits received by the patients subjected to the treatment were due to the serum itself and not to any added value it possessed by reason of the animal having been inoculated with tubercle poison. A Spanish physician, in Barcelona, reports good results from the injection of plain serum in cases of faulty nutrition in children. Indeed, the results reported are quite beyond belief. Its exhibition was followed promptly by an increase of the number of red corpuscles and a gain in weight. He also reported the cure of sixteen cases of chorea in a average of fifteen days, with the serum.

In conclusion it would seem, in the light of our present knowledge, that serum therapy is of value only in those diseases in which it produces an antitoxin and that an antitoxin is produced only in the self-limited diseases.

32 and 33 Sentinel Building.

PROLONGED GESTATION, ACRANIA MONSTROSITY AND APPARENT PLACENTA PREVIA IN ONE OBSTETRICAL CASE.

BY CHARLES REA, M.D.

PHYSICIAN TO CHILDREN'S HOME, YORK, PA.; MEMBER OF AMERICAN MEDICAL ASSOCIATION.
YORK, PA.

The following case, on account of its unique character, will probably be of interest:

About the middle of April, 1897, Mrs. F., 4-para, age 34, engaged me to attend her in confinement which was expected about July 1, 1897. When questioned, she told me her last menstruation occurred September 4, 1896, but did not indulge in sexual intercourse until two days before her next expected menstrual period, or September 30, and that she had not copulated for two months before this period and not at all afterward. Accepting these statements as facts, she should have fallen in labor about July 6, 1897. On June 20, I was summoned to her on account of a "severe period" coming on. Upon arriving at her home and making careful inquiry, I was told that two months before she had passed considerable blood and each time there was very little pain. A vaginal examination showed cervical dilatation to be practically *nil* and hemorrhage decided. Taking everything into consideration, it was decided to be a case of placenta previa. After concluding to dilate and deliver at once, the patient was ordered absolute rest, foot of bed ele-

vated, cool drinks, etc., until an assistant could be procured. The patient when informed of what was proposed to be done strenuously objected and argued that she recovered all right from the attack of bleeding she had two months before and preferred to wait and see if she did not recover from this one. All my persuasion and instructions regarding the dangers of such a course were in vain. The next day when I called the patient was up and walking around the house as though nothing had happened. She was informed that she should send for me at once when the first evidence of her falling in labor occurred as it was then almost due. Nothing more was heard from her until Aug. 5, 1897, when the messenger announced that Mrs. F. had fallen in labor. Upon arriving at the patient's bedside and after thoroughly sterilizing my hands and arms, investigation showed labor well advanced with normal implantation of the placenta. To my surprise and relief, practically no blood was lost before or after delivery, but the child proved to be a monstrosity of the acrania variety. (For an almost exact picture of the monstrosity see cut on page 97 of "J. Lewis Smith's Diseases of Children" 7th Edition.) The vascular exposed mass looked as though it had been bleeding and had been partly covered by a very thin membrane. Probably less than one-half of the brain matter was present. In other words, if a plane had been passed from a point one-half inch above the supra-orbital ridges to the occipital protuberance it would cut off about as much of the brain matter as was absent in the child under consideration. The baby nursed naturally after the first day, but succumbed on the third day.

The first thing to engage our attention is the apparent prolonged period of gestation which, if the woman was not mistaken, was 305 days. We appreciate the fact that all histories regarding time of supposed conception must be accepted with considerable doubt, but, after questioning and requestioning the woman she would invariably tell me she absolutely knew there was no mistake. Inasmuch as several cases have been reported, from perfectly reliable sources, of much longer periods of gestation than this I simply bring out this feature of the case on account of the history seemingly being genuine. In one case, reported by Maur, gestation was believed to have lasted 334 days.

It is quite interesting to read the history of the theories as to the causes of these teratologic objects before the causes were analyzed and considered, from a scientific standpoint. Ambroise Paré,¹ says, "therefore, in times past there have been some, who nothing fearing the Diety, neither Law nor themselves, that is their souls, have so objected and prostrated themselves, that they have thought themselves nothing different from beasts: wherefore atheists, Sodomites, outlaws, forgetful of their own excellency and divinity, and transformed by filthy lust, have not doubted to have filthy and abominable copulation with beasts. This so great, so horrid a crime, for whose expiation all the fires in the world are not sufficient, though they too maliciously crafty have concealed, and the conscious beasts could not utter, yet the generated misshapen issue hath abundantly spoken and declared, by the unspeakable power of God, the revenger and punisher of such impious and horrible actions. For of this various and promiscuous confusion of seeds of different kinds, monsters have been generated and borne, who have been partly men and partly beasts." But it seems the real foundation for the scientific consideration of the subject was laid by Albrecht von Haller. His intelligent and scientific mind enabled him to analyze all the previous theories and make logical deductions. It appears that Bichat, the originator of the science of histology took up the subject where Haller left off. Through his efforts the subject of the study of monstrosities became identified with embryology. We believe now, as was

¹ Ambroise Paré: Surgery, 1579, Johnson's Trans., London, 1634, Book xxv, "Monstrosities and Prodigious."

believed in Bichat's days, that monsters resulting from retardation or arrest of development are partly permanent embryos. Without going deeply into the various theories, it seems the effect of maternal impressions in producing monstrosities is little when we consider that, as yet, not a malformation has been found that is peculiar to the human species. Ballentyne,² in his recent work, expresses his opinion that a definite impression upon a pregnant woman's mind never causes a defect in the fetus closely resembling the thing producing the impression, but he does say that the state of a woman's mind during gestation does have more or less effect upon the unborn infant's development and that the cases which have been advanced to prove effect of maternal impressions have been coincidences rather than the effects of alleged causes. External mechanical influences may act partly or wholly as the cause in some cases, but the most logical explanation is pathologic influences analogous to those which occasion morbid conditions in the body after birth. However, probably in every monstrosity numerous conditions have operated to bring about the anomaly.

That there was an abnormal implantation of the placenta in this patient's uterus, almost any physician would have thought and would have expected alarming hemorrhages at or before birth. The patient being a multipara, the previous nearly painless hemorrhages, etc., seemed to foretell that. This must have been simply a case of menstruation during pregnancy, or a metrorrhagia. Hemorrhages, however, unless caused by a vicious situation of the placenta, are very rare so late in pregnancy unless there has been menstruation during the entire gestation.

DENTAL FACULTIES IN MEDICAL SCHOOLS.

Presented in the Section on Stomatology, at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY RICHARD GRADY, M.D., D.D.S.

BALTIMORE, MD.

There is a sentiment abroad that some dental schools have not the equipment of faculties and instructors that they should have. It is a prerequisite for admission to the National Association of Dental Faculties, that the applicant shall have the endorsement of the board of dental examiners of the State in which it is located; and it is the rule of the National Association of Dental Examiners that an application for recognition by that body must come from a member of the Association of Dental Faculties.

"Dental schools are not being formed now from an educational necessity. Two impulses control this matter: 1, personal ambition to have a position in and be connected with a dental school, for the prominence it is supposed to give; and 2, a purely commercial spirit on the part of medical schools. Over 60 per cent. of our schools are appendages to medical institutions; and nearly every dental school started in these later years has been under this outside influence."

The Committee on Colleges of the National Association of Dental Examiners, recently expressed the view that more should be required to establish the right of dental schools to recognition than the fulfill-

ment of the rules of the Association of Dental Faculties; evidence should be furnished that the teachers are of high standing, and that they and the school have the confidence of the local members of the profession. The committee also called attention to the impropriety of schools advertising as instructors, practitioners who occasionally hold a clinic before the students, but are not a part of the staff of the institution.

While "anybody with fair mechanical ability could pull or fill a tooth, I have seen good fillings inserted in teeth by a man wholly ignorant of the science of dentistry, and we have all seen the botches which educated men have made in attempting a similar operation," yet (in the words of an editorial in the *Dental Cosmos*), "the ability to teach dentistry is an acquisition quite distinct from, though supplemental to, the ability to practice it. So important has the art of teaching become that the study and investigation of its principles now constitute a distinct branch of scientific work, viz., pedagogics. To know dentistry from the point of view of the practitioner is one thing. To know it from the teacher's standpoint implies not only all that is included in the educational equipment of the practitioner, but in addition to this the important qualification of ability to impart successfully this knowledge to others."

The plan of requirements of dental schools, hereafter making application for recognition by the National Association of Dental Examiners, provides that each dental school must have a teaching faculty of at least three professors of dental subjects, namely: for operative dentistry, for dental prosthesis, and for dental pathology and therapeutics; and at least five professors for medical subjects, namely, for anatomy, physiology, chemistry, pathology and for materia medica.

Let us consider one thought in the discussion of "the equipment of faculties and instructors." In none of the dental departments of the medical schools known to us is there, in the teaching faculty, a professor for "dental pathology and therapeutics." The title used by faculties is "M.D., professor of materia medica and therapeutics," as certified to by official documents. Now, we maintain that more than a medical education (so-called) is requisite to teach dental therapeutics. The therapeutics of dentistry, unlike its anatomy, physiology and pathology, differs from that taught in the medical schools. It is medical, surgical and prosthetic. In so far as it is a direction of medical science to the prevention, modification or removal, by medicinal or hygienic remedies, of the causes and effects of disease in the dental organs, it forms part of a physician's practice, just as does the treatment of cerebral, cardiac or pulmonary disease. In so far as it is an application of surgical skill to the extraction of teeth, to the removal of tumors, to the treatment of fractures or of fissured palate, it is simply oral surgery, involving only such knowledge and skill in the use of instruments as every surgeon must possess. But dental therapeutics includes a class of operations which medical men were not taught in medical schools, and which as physicians and surgeons they do not practice. The prevailing and distinguishing feature of dental therapeutics is the art of replacement; replacement of dental structure in such manner and with such material as shall prevent further action of the destructive agencies; replacement of dental organs by substitutes which shall

² Teratogenesis: An inquiry into the causes of monstrosities. History of the Theories of the Past, J. W. Ballentyne, M.D.

physiologically restore impairment of function, and esthetically restore the natural expression of the face; and this a person with a medical education alone is not qualified to teach.

CATAPHORESIS VS. THE DIRECT APPLICATION OF THE GALVANIC CURRENT FOR OBTUNDING SENSITIVE DENTINE AND HOW TO EXCLUDE BOTH.

Presented to the Section on Stomatology at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY W. G. A. BONWILL, D.D.S.

PHILADELPHIA, PA.

When I speak of cataphoresis and the galvanic currents without medicaments, in 1856 to 1859, you will see that with all that has been done by the few workers in our profession, a quarter of a century had passed and no one thought there was anything in electricity until some one in medicine attempted to keep up with electricity in other branches and carry medicaments through the tissues as copper is supposed to be carried from one pole of a battery to the other as in electroplating; and now some dentist takes that up and tells us that cocain can be carried through the dense tissue of dentinal tubuli, and every one is ready to take it up as an insignia that makes it no better than an advertisement that he can perform all operations on the teeth painlessly. I remember, when I sent out a circular, on going into a new town in Delaware to get practice, what a commotion was set up and how every one was ready to try the new obtunder. Now after so many years have passed and this comes again to the light, do you wonder that I am more amused than chagrined?

At the meeting of the Odontological Society of New York, in October last, I presented before them the original patent gotten in 1859 for obtunding dentine and extracting pulps by the electric current alone. I made no effort at the time, nor since, to sell a single right to any one.

At this late date I submit to you the original document obtained by me in 1859 for doing then by the current alone what you are now called upon to believe can only be done by cataphoresis.

Aside from my own statement that I did successfully produce analgesia by the current alone as early as 1856 to 1859, you may have the many strong testimonials of Dr. Horton of Cleveland, Ohio, who has been doing the same thing by an improved galvanic battery and apparatus. "Why did I not continue to use it?" My reply is that I found, while experimenting with electricity, something better, which I have used all these years with other additional means.

Now, what have I to say about cataphoresis? Is it a fact that a drug can be dissolved in water, or any other media, and be made to traverse the dentinal tubuli and enter the pulp chamber and produce an anesthetic or analgesic effect by osmosis? Or can it directly paralyze the sensitive dentine upon its surface and sufficiently deep to enable the operator to cut with impunity, painlessly, as is claimed for most obtunders now found in the market? All who support this, claim that some effect is produced through osmosis and electricity the power that enables the drug to produce its effect by direct circulation through the tubuli of dentine.

I should not attempt to quibble over osmosis, or how or what does produce this supposed effect, but my long experience, dating further back than Dr. Richardson of London, entitles me to ask what is the real agent in this so-called wonderful discovery after nearly one-half a century's burial.

There are so many means of influencing, not only the human being, but all animals below man, as to make them believe almost anything you wish, even to the complete annulling of pain, that we must be very conversant with past history in this line to enable us to say what agent has produced this so-called cataphoresis or, as with other pain annullers, what is the true philosophy or *modus operandi* in analgesia? It is a subject that has called forth the thought and research of men through all time, and there is still a mystery, though the agents are still appearing and the last is claimed as the best.

Osmosis, according to the best authorities, can only take place between two fluids of dissimilar natures or densities or gravities, where a porous membrane of tissue intervenes, or where a porous porcelain cup is used, as where salt of different specific gravity is used on either side of a porous membrane, when the fluids will in a short time, without any electricity, become of the same strength or gravity; or, in a Bunsen battery, where the porous porcelain cup that holds the bichromate solution, or nitric acid, and the glass or outer cup holding the sulphuric acid solution of 1 to 12, when the current is passed, what effect is produced on the liquids and what becomes of the bichromate or sulphuric acid? Do they pass around through the galvanic apparatus or coil and through the interrupter? You know this can not be. They are simply neutralized and lose their power to produce an electric current. How can copper be carried through a porous cup and be deposited upon the opposite pole? How can you take the fluid containing cocain and pass it through a membrane that is not porous? Dentine is porous only when the tooth has been extracted and dried and is void of all organic matter. So long as it is in the mouth it is full of fluid that is not interchangeable by osmosis, unless you can produce in the pulp chamber and canal a different density to the fluids in the peridentium. If equilibrium exist between this medium of dentine on either side of it, then there is a *statu quo* condition and no osmosis. You might as well tell me that a cup can be made of dentine to take the place of the ordinary porous porcelain or burnt clay cup in a Bunsen battery.

Now, when I assert that in 1856 I did all this obtunding by the simple galvanic current, without dam or any other adjunct, and that Dr. Horton has done the same thing with his improved instrument and battery, what can you say in refutation? Why will you persist in this absolutely useless and unnecessary procedure; in loss of time; demoralizing your patients; trying to believe you are doing something that was never done before and is superior to all that was ever done in the past history of dentistry?

It is well to try to alleviate pain in any operation, but when all this can be done without it, and the patient is enabled to see that dentistry is not the inhuman thing dentists would have them conceive, and have them feel and know that they can be taught to bear all the pain consequent upon any operation upon the teeth, in excavating or removing pulp why should you not adopt means long ago in your grasp.

From the many experiments of others in electro-

therapeutics, as far back as 1860 osmosis was proven to take place by a current of electricity through a porous membrane or diaphragm, but never through bone, either in the living or dead subject; and even when the osmosis was affected through a porous animal structure or membrane or porous cup, it was only done after many hours. Teeth were extracted by electricity, in this city, as early as 1859, perhaps 1856, but it was only by the shock produced at the instant the forceps were applied and which produced a diversion of the will force, by causing a sudden and violent inhalation into the lungs, and while the lungs remained inflated, the effect was good, for the senses were for the instant submerged or subjugated.

This was taken up quickly by the profession everywhere, but it failed because dentists generally had no idea of the agent or how to use it, or why it produced the effect. They did not see its simple philosophy. They supposed it was the potential and specific effect of the galvanic battery current with an interrupter. But this was not true in the manner in which it was practiced. Thousands of batteries were sold, and ignorance of the real cause of success made it a curse rather than a blessing.

I bought an instrument, such as was to be had then and which was recommended, and it worked well for a single extraction, but not when I had several teeth to remove, as I was compelled to do at that time in the country, for I had no experience nor the means to save human teeth. I soon found that the public preferred extraction because it was cheaper. But from my use of the battery and by becoming familiar with its working upon myself and patients, I found that the continuous current, or when interrupted several thousand times a minute, would annul pain when the positive pole was directly applied to the tooth in excavating and the negative pole on the face or in the hand with no dam or other agent.

All of this work, however, was preceded by experiments in the use of chloroform directly upon myself. That I may have you understand the steps leading up to the discoveries and principles involved, and the cause of failures in so many otherwise good agents that are overlooked and abandoned: and why I assert that all this cataphoresis in dentine is only the work of the current pure and simple; and how many agents we have had at our disposal that, had dentists only learned to apply scientifically, we would not be trying everything offered as obtunders or anesthetics or analgesics.

You have certainly had enough of obtunders in the past decade alone to freight a ship, and each has had its friends, but is now giving way to cataphoresis, and the dealers are delighted to have another craze and stock the dental market with enough batteries to sink several fortunes, and soon to be set aside for another. The world craves some agent to quell the simplest stomach-ache, that as boys we thought nothing of. We are driving people to seek these agents to destroy one of nature's most gracious and beneficent gifts—pain—and lowering the moral status of mankind and rendering them hypersensitive to every change of the atmosphere. This is wrong, and the medical world is no better. It is well for major operations in surgery, but not where your ingenuity can plan not to use these agents.

I had learned the use of chloroform and ether from my father, and particularly from an M.D. who was exploiting these new agents and also had a gal-

vanic battery. At that time (1856) it was not known that chloroform had any other than an anesthetic effect. It was not discovered that it could be taken to a degree or in quantity to produce what is now known as analgesia.

You will now see the first dawning in my mind of the nature of these annihilators of pain, for the application was first made upon myself, and was administered by myself, which led to the discovery that chloroform could be taken to that extent that I could excavate my own carious cavities without pain and yet be sensible of the sense of touch and ability to perform the operation upon myself. It was an amazing thing to find that while the sensitive dentine was so obtunded that I could cut it with impunity, yet the special sense of hearing and touch was exaggerated. The excavator seemed to me as large as a hoe and the cavity as capacious as a bushel basket. There was no pain and my will sense was not subjugated, only the voluntary mind had been partially annulled. I could scarcely believe my own senses. Yet several separate trials convinced me that I had discovered a new property or rather phenomenon—the analgesic effects of ether and especially of chloroform.

Chloroform, while it would do what I wanted, would make my patients too sick and I had to abandon its use.

It was then that the battery, for extractions alone, was first brought out in Philadelphia. I mentioned above the philosophy of shock in its action on respiration, and soon had it exemplified to the satisfaction of the patient that, while electricity would annul pain in dentine, and living pulps (if not inflamed) could be removed, yet the too strong application of the current gave the patient such a severe shock while excavating that a violent inspiration led me to exclaim, "nature's anesthetic," and I then saw it was diversion of the will power, for when the lungs were being inflated so violently, the will could not take cognizance of actual pain. It was for the instant complete. Let any of you hurt a finger and how soon it is put in the mouth and a violent inhalation taken several times until pain is relieved. The infant in crying violently, while in pain from an accident, is relieved and falls to sleep from the constant sobbing and increased inspiration. All temporary teeth I extract by this one sudden inhalation or diversion of the will, without a tear nor complaint. Two or three can be extracted while the breath is held in the lungs.

This led to the discovery that rapid breathing for sixty to ninety seconds, at the rate of 100 to the minute, would produce such an obtundity of the nerves and nerve centers that analgesia would be produced and the patient still be conscious of touch. This enabled me to perform all cases of excavating—extracting both teeth and the bony pulp, as well as all minor operations in surgery. A single respiration quickly taken and the breath held in the lungs will suffice for many trifling operations and all that is needed in extracting the temporary and permanent teeth of children. This was the birth of analgesia, in 1856, as proven upon my own person while operating upon myself.

This property of all anesthetics is very little known by medical men, and they have missed a very important part of anesthesia. Analgesia should be better understood and the application of rapid respiration would come into use in thousands of minor cases of operations where the custom is to completely anesthetize the

subject. Let surgeons and dentists learn how to produce this effect and ether, chloroform and gas would no longer be used in three-fourths of the cases. In many cases of midwifery it is all that is desirable.

Let any one imagine that they are blowing a fire to make it blaze, taking full inhalations and forcibly ejecting or blowing, which can be done at least 100 times a minute, and while the patient is doing this the operator should talk to him, say no pain will be produced and urging him to breathe in this manner until sixty seconds have passed, when the patient can not feel any pain, as the voluntary system is subdued. The pneumogastric nerve now says, you can not go on as life would become extinct. For the next three minutes the respiration is only about six to the minute, showing the blood has been over-oxygenated. The patient has to be urged to breathe. When this is done previous to using ether or chloroform only one-half the quantity is used, the effect is more profound and there is not as much danger. Since this discovery of the rapid breathing method, in 1872, although analgesia was discovered by me in 1856, and was the stepping-stone thereto, I have used no other means of painless surgery in dentistry.

Cataphoresis is not a fact as applied to sensitive dentine and should have no place in dentistry.

You now know why I abandoned electricity for obtunding sensitive dentine and extracting; for this revelation of how nature relieves gave me the clue to a brighter step which dentists have been slow to recognize as a fact. Had they done so, then you would not today be looking for any other agent in most of the cases it is our lot to have.

NOTE.—For the history of rapid breathing and its applications, etc., see *Scientific American* supplement, April 9, 1881, No. 275, p. 4386.

SOCIETY PROCEEDINGS.

Michigan State Medical Society.

The Thirty-third Annual Meeting was held in Detroit, May 5 and 6, 1898.

The Society met in Harmonie Hall, with the President, Dr. JOSEPH B. GRISWOLD of Grand Rapids, in the chair.

Prayer was offered by Rev. JOHN REID, D.D., of Detroit.

An address of welcome was delivered by Mr. BLADES, city controller, in the absence of the Hon. WM. C. MAYBURY, Mayor of Detroit.

The annual reports of the secretary, treasurer and publication committee were read and adopted.

The committee to petition the legislature with reference to an improved plan of registering births and deaths, Dr. Leartus Connor, chairman, reported, and the report was adopted.

Dr. C. HENRI LEONARD of Detroit, chairman of the committee to take action on establishing a National Bureau of Health, read the report of this committee, as follows:

REPORT OF COMMITTEE ON THE ESTABLISHMENT OF A NATIONAL BOARD OR BUREAU OF HEALTH.

Mr. President and members of the Michigan State Medical Society: As your chairman of this committee I have to report as follows:

During the past year there have been two quite prominent bills introduced into Congress looking toward the end desired. One of these bills was so imperfect that it met with almost unanimous objections from the medical press of the United States, as well as from the medical men to whom it was submitted for approval. The other bill is very bulky in its provisions but, shorn of some of these, would have been quite acceptable to most of the profession outside of the Marine-Hospital clique; it was this bill that our committee would have been called upon to enlist your sympathies for, had it not been for the outbreak of hostilities with Spain. The momentous questions concerning Cuba have so overshadowed everything

of a purely civil nature that this bill, with sundry others, has been relegated to a more convenient season for discussion by Congress, though not "pigeonholed." This bill, to give a brief *résumé*, incorporates within it the following main propositions:

1. To gather information upon the state of the public health and the existence of contagious disease in foreign countries through the consulates of the United States Government; to digest and communicate the same to all government posts and health authorities of our country; through medical officers attached to the consulates, when requested by the masters of vessels destined for ports of the United States, to inspect the vessels, cargoes, crews and passengers (including their personal effects), to use measures for cleansing and disinfection, and to vaccinate those requiring vaccination (all at the expense of the vessel), to furnish bills of health relative to the port of departure and full dealing with the vessel, or to notify the Bureau by telegraph of neglect or refusal to accept such service.

2. To serve as a medium of intelligence in sanitary matters, including vital statistics, between health authorities throughout the United States.

3. To inspect the various quarantine stations of the United States from time to time; to investigate outbreaks of pestilential disease in any part of the Union; to report such inspections and investigations; to recommend to local health authorities needed preventive and suppressive measures.

4. To conduct chemic, physiologic and pathologic investigations in the interest of sanitation.

5. To publish and distribute documents relative to public health.

This bill was drafted by a special committee from the AMERICAN MEDICAL ASSOCIATION and it has been endorsed and advocated by the American Public Health Association—the largest body of sanitarians in the whole world at the present time.

The Marine-Hospital corps is against its passage purely from personal and selfish reasons, as when passed, it makes them subsidiary to the Bureau, and so curtails some of the fat offices that are now at the disposal of the Marine-Hospital Service.

The bill as proposed recognizes each State of the Union, in that a member shall be chosen from each State to represent it on the general national board or Health Bureau, thus forming a sort of advisory council to the commissioner of public health, much as the President of the United States now has his cabinet officers about him for advice and counsel.

Your committee has just learned that the representative for Detroit in the House, Mr. Corliss, has recently introduced a bill to enlarge the Marine-Hospital and naval interests, so as to embrace the controlling of the States in medical matters by it, and so wipe out the chances of getting the bill passed that has met with the approval of the majority of medical men of the United States, and which we have above given the summary of. This we regard as inimical to the best interests of medical and sanitary control. We all know the offensive ways of these "water" medical boards, and your committee verily believes it will be a sorry day for the medical profession of the United States when this general control shall pass under the thumb of the bickering Marine-Hospital Service. Hence we offer the following resolutions for immediate action of this Society:

Resolved, That we, the members of the Michigan State Medical Society, view with alarm any attempts of our government to substitute a Marine-Hospital bill or medical Navy bill for the one now before Congress that has met with the endorsement of the American Public Health Association and the approval of the committee from the AMERICAN MEDICAL ASSOCIATION, the largest body of medical men on this continent.

Resolved, further, That a copy of these resolutions be sent to Representative Corliss, asking for his withdrawal of the bill he introduced, if possible, as being unrepresentative of the wishes of the medical profession of the United States.

Resolved, further, That a copy of these resolutions be sent to each Michigan Congressman asking for his help to defeat the Corliss bill, in case it is not or can not be withdrawn, and that each member of this Society write a personal letter to his Representative, asking him to use every means possible to defeat the Corliss bill.

Resolved, further, That the representatives from this Society to the next meeting of the AMERICAN MEDICAL ASSOCIATION be instructed to advocate measures looking to the defeat of this Corliss bill, when they meet with that great body of medical men so soon to assemble at Denver.

Resolved, That a copy of these resolutions be sent to the Editor of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION for publication.

Signed,

C. HENRI LEONARD, Chairman,
A. W. ALVORD,
D. W. C. WADE.

On motion, the report was unanimously adopted.

The committee appointed to consider the establishment of a Michigan State Medical Society journal, reported through the chairman, Dr. Hugh McColl of Lapeer, that after considerable correspondence with States which publish their transactions in journal form, the committee does not recommend any change in the present method, namely, of issuing an annual volume of Transactions.

The report was adopted.

Dr. H. W. LONGYEAR of Detroit, delivered the annual address as orator of the section on obstetrics and gynecology, entitled

CONSERVATISM IN ABDOMINAL AND GYNECIC SURGERY.

He said the history of abdominal and gynecic surgery showed a very slow state of development until the advent of asepticism gave it an impetus that has caused more history to be written on these two branches of the surgical art than was recorded during all preceding times. Reference was made to the discoveries of Lister, which was the beginning of the bright era of surgery. The fearlessness of the peritoneal cavity had led to extensive experimentation within its once sacred precincts, much of which is already yielding large returns in the lessening of human suffering, the saving of human life and the glorification of the science and art of nineteenth century surgery. There was already springing up a class of operators in America, men of experience, skill and integrity, who were adopting the conservative plan in the matter of diseased appendages and of hysterectomy. Normal ovaries were not removed, and some operators even advocate the leaving of small fragments of healthy ovarian tissue, when possible, for the purpose of preserving the natural functionation of the generative organs. Healthy tubes were left *in situ*, and catarrhal uteri were treated by other methods than by removal.

Dr. WILLIAM FULLER of Grand Rapids, delivered the annual address as orator of the section on surgery and ophthalmology, entitled

THE RELATION OF ANATOMY TO SURGERY AND MEDICINE.

He said, the present neglect of anatomy had arisen from the establishment of the laboratories in chemistry, physiology, pathology and bacteriology, besides the introduction of studies upon comparative anatomy and embryology, all of which might be of great scientific value, but certainly they had in his opinion deprived the medical student of the time and opportunity necessary to the acquisition of that knowledge which in practice will be of everyday use to him in the diagnosis of disease and at the side of the operating table. He believes that advanced courses of instruction, as preparation for the practice of specialties, for positions in the army and navy, railway surgeons, health officers, physicians of asylums and other public institutions, would be of great service in qualifying men to fill these responsible positions. If such degrees of qualifications were established by medical schools, it would surely follow that such degrees would be recognized by legislation, and that appointments would be made from among those who were especially adapted by a particular course of study. If some such plan of medical education was adopted there would be less excuse for the neglect of the primary and practical branches of medicine.

JOINT SESSION OF THE THREE SECTIONS.

At this session there was a symposium on

SEPTIC DISEASES OF THE ABDOMEN AND PELVIS.

Dr. CHARLES T. MCCLINTOCK of Detroit, discussed the etiology. For the production of sepsis in the abdominal and pelvic organs, as elsewhere in the body, two things were necessary: 1. The source of infection. Without bacteria there is no sepsis. 2. Lowered resistance of the tissues; healthy normal tissue does not suppurate. It was only in dead, wounded or weakened tissue that the suppurative bacteria grew and produced pus. The source of infection may be a suppurating focus in any portion of the body. We may have a peritonitis, the source of infection being an erysipelas of the face, or a suppuration in the foot. We have abscess of the liver traceable to amebic dysentery located in the colon. Of the causes that enfeeble tissues and render them susceptible to suppurative, probably inflammation is the most important, and this inflammation may be brought about in several ways. There are many examples where infection is traced to the open Fallopian tubes. Instances were cited. Tuberculosis of the genital organs is much more common in the male than in the female, yet peritoneal tuberculosis is very rare in the male, while not uncommon in the female, apparently pointing to infection through the Fallopian tubes.

Dr. HERBERT M. KING of Grand Rapids followed with a contribution on the blood. He showed a few of the practical advantages accruing to the practitioner by examinations of the blood in the diseases under discussion. There are generally

recognized three distinct degrees, if not kinds, of sepsis, in any one variety of which the blood presents certain modifications not always, however, sufficiently marked to make the differential diagnosis a matter of certainty. The first and mildest form, termed by Bergmann fermentative fever, septic or resorption fever, is by many thought to be in reality a very mild sepsis, where for unknown reasons the pathogenic micro-organisms are at least virulent or where conditions of the body are such as to overcome immediately the toxic effects and to resist development from absorption of further toxic material. Such so-called reaction as tends to the absorption of small blood clots, post-operative, or following extravasation of blood from contusions, or perhaps a slight febrile reaction occasionally following parturition, subsiding within a few hours and without any untoward results, are all representative of this form of sepsis. In these cases the blood was less often studied.

The second form or degree is that most frequently met with, the one in which the reaction in the blood is most marked and characteristic, and in which the natural course tends to recovery, but which by long continuance of the septic leak in the circulation, or the supervention of the third and most malignant form, not rarely terminates fatally. This is a septic intoxication due to the entrance into the circulation of the toxic products of pyogenic organisms, but not to any extent of the organisms themselves. This is the common puerperal sepsis ending in recovery; or appendicitis, where the inflammatory focus remains localized; or the common form terminating in recovery following abdominal section, etc.

True septicemia constitutes the third form or degree of sepsis, and is distinguished from the other forms by the entrance into the circulation of sufficient numbers of pyogenic organisms themselves to overcome resistance, either in the form of phagocytosis or antitoxemia.

Blood examinations are of inestimable value as diagnostic aids in distinguishing between sepsis arising from pelvic and abdominal sources and certain diseases, which from clinical appearances simulate it closely. The state of the blood also aids greatly in the prognosis of septic disease, and is an indication for operative interference. Surgeons are more and more availing themselves of its aid, and with the establishment of a clearer comprehension of the causes of leucocytosis and the origin and destiny of the various elements, both normal and pathologic in the blood, there will no doubt be thrown a new light upon the history of the disease under discussion, as well as upon many others.

Dr. H. B. OSBORNE of Kalamazoo dealt with septic infection of the peritoneal cavity, its diagnosis and treatment from a medical standpoint. He enumerated some of the standard measures used in the treatment of the disease. He thought that we still had other valuable aids in the nucleins, the antistreptococcic serum, and the allotropic form of silver, brought to the attention of the profession by Dr. Credé of Dresden, at the International Medical Congress held in Moscow last year. This preparation is readily absorbed when applied to the skin and is soon found in the blood, the intestinal contents and the urine. The nucleins may be used per os and hypodermically. When a microscopic examination shows the presence of streptococcus infection, antistreptococcic serum should be used. In peritonitis arising from appendicitis, just so soon as the diagnosis is fully made he thinks the case becomes a surgical one and operative interference should not be delayed. When peritonitis arises from tubal infection a longer delay is justifiable with the hope of relieving the patient by remedial agents.

Dr. HUGH MCCOLL of Lapeer discussed the medical treatment of septic peritonitis. The medical treatment of septic infection of any part of the great lymph sac (the peritoneum) is much the same. Whether the poison is in the pelvic cavity or in the region of the appendix, or in the liver or kidney, the cardinal principles of treatment are similar. The first and most important of all was rest, absolute rest. The patient should be put to bed and kept perfectly quiet till fully convalescent. If the temperature is high and pain severe, the cold coil will give relief and diminish the tendency to extension of the inflammatory process. In some cases, however, heat is better borne and should be continuous at as high a degree as the patient can bear, never allowing the temperature to fall. With either the hot or cold constantly kept up the diminution of blood supply is brought about and the exudate is lessened. Hot vaginal and rectal douches were very useful to relieve pain and to supplement the external applications when the inflammation is confined to the pelvis. Liquid nourishment in concentrated form should be used and no solids given till convalescence is established.

Dr. WILLIAM F. METCALF of Detroit spoke of the surgical treatment of septic diseases of the pelvis, and outlined the general principles which governed him in dealing with these

conditions. The character of the invading micro-organism, the location of the resulting lesions, the reflex disturbances, the resistance of the tissues, the age, circumstances and environment of the patient were the determining factors in the method to be employed. In cases of endocervicitis the application of equal parts of Churchill's tincture of iodine and carbolic acid was effectual. In many cases the sphincter at the internal os guards effectually the corporeal endometrium from invasion.

The author next considered septic invasion of the endometrium of the non-pregnant uterus. When a collection of pus is below the wall which separates the pelvic from the abdominal cavity, free vaginal incision and drainage were all that was required, provided the damage to the uterus and its appendages could be remedied, and in many cases where a radical operation was indicated, it was advisable to precede it by vaginal incision to relieve septic symptoms and increase the vitality of the patient. A typical case was cited in support of the above statement. The experience of the author leads him to assert that there is much less shock attending work done through the vagina than by the abdomen.

Dr. CHARLES B. NANCREDE of Ann Arbor spoke on the surgical treatment of peritonitis and stated, in the form of propositions, certain facts as they appeared to him, without any explanation or defense of the position assumed on account of the great scope of the subject and the limited time at his disposal. Post-operative peritonitis or that following infective processes in a parietal wound was usually a mixed infection, the predominating organisms being pyogenic cocci, rarely bacilli. The occasional presence of bacilli in conjunction with other micro-organisms, *i. e.*, mixed infection, shows that the surgeon is not always blameworthy because bacilli may either intensify the action of other germs present in too small number to be harmful or actually be the chief factors in a peritonitis following operative interference. Intestinal paresis can best be prevented by early operation because it results from an infective process which can often be successfully combatted in its earliest stages. Increased frequency of pulse, especially when out of proportion to either temperature or respiration, more surely indicates the need for operation than any other symptom. High temperature, great pain and abdominal distension, with or without vomiting, may be and often are sufficient indications, but may all be absent in some cases most urgently demanding surgical interference. Any extension of a peritonitis, shown either by an increase of the local or general symptoms, still more by both, usually demands prompt intervention as a life-saving measure. Generalized, *i. e.*, septic peritonitis, can not be efficiently treated by mere irrigation and the introduction of drainage tubes. Too much stress can not be laid upon the imperative necessity of previously walling off of the general peritoneal cavity by careful packing with gauze when opening any intra-abdominal pus collection, which alone renders the procedure either justifiable or safe. The pus, when possible, should be removed by pieces of gauze or sponges, rather than by irrigation, which might diffuse the infective material over a wider area. Irrigation, however, is sometimes the sole or most efficacious means of removing the pus. When doubt exists as to the necessity for drainage, the introduction into the peritoneal cavity of one or two pints of warm saline solution, close suturing of the wound, and elevation of the foot of the bed for about eighteen inches will often prove sufficient. This position tends to relieve the abdominal distention, favors the normal peritoneal current toward the diaphragm, the peritoneal covering of which Clark has shown plays an important rôle in the removal of fluids and germs from the abdominal cavity. Assumed immediately after operation, it materially lessens accumulation of blood in the abdominal viscera, one of the most important factors in preventing shock and lessens the tendency to oozing. Codein rather than morphia must be employed to secure sleep. Morphia if never indicated in the opinion of the author as a curative agent and should be rarely needed to secure sleep. Tubercular peritonitis is best treated by incision, separation of soft adhesions, free irrigation and closure of the wound without drainage.

Dr. W. H. HAUGHEY of Battle Creek read a paper in which he described "The Haughey Suture." A description of this suture was published in the JOURNAL Feb. 20, 1897, p. 346.

Dr. JOSEPH B. GRISWOLD delivered the annual address as President, entitled

WHERE ARE THE NINE?

He outlined the history of the art of medicine from the earliest times and traced the growth and development of it down through the Greek and Roman schools to date, referring in the highest terms to the code under which Hippocrates practiced as perhaps as perfect a one as that under which most physi-

cians worked today. The speaker discriminated between medicine as a trade and medicine as a profession, pointing out that the difference was that existing between manual and mental labor. He censured severely the indiscriminate publication of successful surgical operations in the daily press as being on a par with the efforts of the tradesman to advertise his business. Who benefits by these publications but the operator? The habit was both undignified and pernicious. In spite of the recognized desire of newspaper reporters to get any and all the news they could, all high-minded physicians should refuse to cater to the natural inclination to put themselves in print. He referred to the necessity for every physician to keep himself in touch with the development of the profession. In these days, when tradesmen of all classes are high school, if not college, students, have their trade journals and maintain a high standard of education, the physician must keep up a continual course of study for the sake of the dignity of the profession. Dr. Griswold dwelt on the subject of medical legislation and said that all attempts in that line in Michigan had proved abortive. Nothing had been done to free the people of the State from parasitic quacks and sham doctors. He accounted for the lack of such legislation on the ground that every bill presented met with violent opposition from the profession itself, and every bill emanating from the profession was looked upon by the legislature with suspicion.

The Chairman of the Executive Committee, Dr. E. S. SHERRILL, had prepared an excellent entertainment which followed the President's address.

In the Section on Obstetrics and Gynecology Dr. JAMES G. LYNDY of Ann Arbor reported two interesting cases. The first was an unusually large ovarian tumor with numerous complications, the details of which were clearly set forth. Six weeks after operation, when the woman had gained probably twenty or twenty-five pounds in weight, she weighed 154 pounds, just 111 pounds less than before operation, so that the speaker estimated the weight of the tumor at 125 pounds, the largest tumor, so far as he knew, that had ever been successfully removed in the State of Michigan. The second case was one in which the production of premature labor was scarcely to be considered on account of the unfavorable position of the cervix and uterine axis, which would render the use of forceps, version or embryotomy unquestionable, and, in the opinion of those who saw the case, more formidable and dangerous than Cæsarean section. The author consequently selected the latter and decided that the Porro-Mueller modification was the procedure best adapted to the case. The case emphasized the value as well as the necessity of seeing such patients early, carefully weighing the value of each and every procedure and electing the one best adapted to the case, as well as the time most favorable for its performance.

Dr. A. N. COLLINS of Detroit, discussed the practical value of proper diagnosis of presentation in instrumental delivery. He said that if we are to use forceps intelligently, it is necessary to use them in conjunction with our knowledge of position as rotators first, as pulling instruments second. When we have become skilled in this, the cases will be found few and far between where the light Eliot forceps will not answer all purposes, and we will not need the lithotrite attachment except in cases demanding craniotomy.

Dr. J. PLAYFAIR McMURRICH of Ann Arbor, reported an exceedingly interesting case of fusion of two kidneys. The speaker had looked over the literature of the subject of anomalies of the kidney as far back as 1623, and had only been able to find twenty-seven recorded cases similar to the one he had shown, his being the twenty-eighth case.

Dr. J. A. PORTER of Brooklyn reported an interesting case of kraurosis vulvæ.

Dr. E. M. HOUGHTON of Detroit read a paper entitled "Ergot Aseptic."

Dr. J. H. KELLOGG of Battle Creek, contributed a paper in which he dwelt upon physical training as an essential factor in the radical curative treatment of the chronic pelvic disorders of women.

In the Section on General Medicine Dr. William Fuller of Grand Rapids, exhibited several interesting pathological specimens, Dr. F. G. NOVY of Ann Arbor, discussed the subject of, 1, the disinfection of rooms, and 2, the etiology of yellow fever.

Dr. C. D. AARON of Detroit, spoke of chronic dyspepsia and chronic catarrh of the stomach.

Dr. A. W. CRANE of Kalamazoo, read a paper in which he dwelt upon the missing links in the chemical examination of the blood.

Dr. C. G. JENNINGS of Detroit, made some remarks on infantile scurvy in Michigan. He was followed by Dr. F. W. ROBINS of Detroit, who spoke on disease of the seminal vesicles.

In this Section, other papers that were read are as follows:

"Epidemic Jaundice," by Dr. E. H. Pomeroy of Calumet; "Sensory Nerve Endings in Striped Muscles," by Dr. G. C. Huber of Ann Arbor; "Syphilis of the Nervous System," by Dr. Charles W. Hitchcock of Detroit; "Vapor Massage in the Treatment of Respiratory and Aural Affections," by Dr. H. M. Dunlap of Battle Creek; "Minute Pathology of Acute Pancreatitis," by Dr. A. S. Warthin of Ann Arbor; "Antitoxin and Intubation, with a Report of One Hundred Cases," by Dr. B. R. Shurly of Detroit; and "Saline Cathartics," Dr. A. R. Cushny of Ann Arbor.

Dr. SAMUEL BELL of Newberry, contributed a paper in which he spoke of some of the results of the administration of the thyroid extract upon the red and white corpuscles and hemoglobin in cases of anemia associated with melancholia.

In the Section on Surgery and Ophthalmology, Dr. C. D. Aaron spoke of transillumination of the stomach, and made a demonstration upon a living subject.

Dr. W. F. STRANGWAYS of Flint, read a paper entitled "The Four Tonsils; Some Things Experience has Taught me."

Dr. H. O. WALKER of Detroit, read a paper on the radical cure of hernia by the Fuller method, and reported interesting cases.

Dr. I. N. BRAINERD of Alma, reported cases of brain surgery.

Dr. THEODORE MCGRAW of Detroit, discussed Bottini's operation.

Dr. J. HENRY CARSTENS of Detroit, read a paper on nephrectomy.

Dr. FRITZ MAASS of Detroit, spoke on the subject of the importance of rapid pulse in appendicitis. Does it contra-indicate operation? Dr. S. C. Graves of Grand Rapids, followed with reflections on the treatment of appendicitis.

Dr. F. B. WALKER of Detroit, read a paper entitled "Some Remarks on the Practice of Surgery."

The following officers were elected for the ensuing year: President, E. L. Shurly of Detroit; first vice-president, A. W. Alvord of Battle Creek; second vice-president, Rush McNair of Kalamazoo; third vice-president, D. W. C. Wade of Kolly; fourth vice-president, J. Van der Laan of Muskegon; recording secretary, Collins H. Johnston of Grand Rapids; treasurer, C. E. Hooker of Grand Rapids. Place of meeting, Kalamazoo.

Medical and Chirurgical Faculty of the State of Maryland.

One Hundredth Annual Session, held at the Hall of the Faculty at Baltimore, April 26 to 29, 1898.

FIRST DAY—AFTERNOON SESSION.

The session was called to order at 12 o'clock noon, Dr. CHAS. M. ELLIS of Elkton, President, in the chair. Drs. J. WILLIAMS LORD and ROBERT T. WILSON, Secretaries.

Dr. CHARLES M. ELLIS, the President, spoke of the improved financial condition of the Faculty, and referred to the fact that in one year we would celebrate the completion of the one hundred years of existence as a medical society, and we hoped then to have all our debts paid and a sum of money as a surplus laid by. Up to the present time fifty-one members had applied for admission.

Dr. J. B. PURNELL of Snow Hill, then read a paper on "School Desks, Eyesight, etc., Cases in Practice, Alcohol and the Gastric Secretions," in which he spoke of the size of the school desk in proportion to the children using them, and the effects it had on the eyesight, and referred also to the adjustable school desk. He mentioned several cases in which he had especially good results from the use of ordinary drugs, and in conclusion, referred to some of the ill effects of alcohol on gastric secretion.

Dr. EDWARD ANDERSON of Rockville, read a paper entitled

THE ANTISEPTIC OR GERMICIDAL TREATMENT OF DISEASE.

He said that we should not rely too much on text-books but use our own experience. We do not remember in using germicides that the blood has marked germicidal properties, and we should also bear in mind that such substances as common salt have a certain amount of antiseptic and germicidal power. In many cases of infant diarrhea he had found great benefit from antiseptics, and thinks that as soon as physicians cease to consider these as local troubles, the better it will be for the patients themselves.

Dr. W. B. PLATT made report of

THIRTY-FIVE CASES OF HIP-JOINT DISEASE TREATED AT THE ROBERT GARRETT HOSPITAL FOR CHILDREN.

He said that hip-joint trouble is one of the most tractable diseases when treated early, but when treated late, one of the most intractable diseases. There is always a serious question about when to operate and when not to operate. Sometimes

it is better to do it early and sometimes late. It depends on the condition of the patient, surroundings, etc. Some cases can not be kept in the hospital long and do not recuperate properly after the operation. The results after resection of the hip-joint are often very good even when done late. He had two or three cases of his own in mind—two doing well, and one not so well. One is wearing a brace and high shoe. The third case died of shock soon after the operation, but died outside of the hospital. Some cases will recover after careful currying of the sinuses and cleaning them out. Hip-joint cases are extremely susceptible to eruptive diseases. He noticed that in the large number of cases he had in the Robert Garrett Hospital those with hip-joint trouble had been especially affected by such diseases as measles and scarlet fever. Joint diseases are usually attributed to injury, but this cause can not always be relied upon. In nine out of his thirty-five cases there was a clear history of injury. In eleven the right side was affected, and in twenty the left side was affected, and in these thirty-five, seventeen were boys and eighteen girls. Twenty-three had no sinus, and twelve had them. He showed two very interesting cases of double hip-joint disease, which were making a very good recovery.

Dr. ANDERSON, in commenting on this paper, said that he had often noticed a great amount of counter-irritation, and that when one hip became diseased the other grew better. He noticed also that in cases of consumption, when sinus was established, the lung trouble often grew better.

Dr. PLATT said that it had been said that heredity played a great part in these hip-joint diseases, some asserting that it was hereditary for two generations back. Tuberculosis is so common that it is a little uncertain whether that has the influence it is said to have. We know that so many of these cases die of tuberculosis, but he did not think that the joint trouble was necessarily the cause of the tuberculosis. There is no reason why these hip-joint cases should die, and in fact, many do not die.

Dr. J. C. HARRIS spoke of the extreme tenacity of life exhibited by some cases of hip disease and instanced cases in his own recollection.

EVENING SESSION.

After reading the minutes of the previous meeting, Dr. CHARLES M. ELLIS, President, delivered his address entitled

THE COUNTRY DOCTOR.

He showed how the country doctor differed from the town doctor; what his needs were and the difficulties for overcoming them, and finally made some suggestions for helping him. He made no attempt to throw around him the glamor of romance and poetry, but exhibited the man only as he knows him, with all his virtues and his vices; often without the proper equipment; with no help at hand as in the case of the city physician. He then gave a very minute description of the life, habits and characteristics of the country doctor. Many a physician in the country grows to be a very important man, and takes the lead in his community, and such a man may have many faults, but they are known more to himself than to his neighbors. Such a man gains the respect of all around him, and soon grows into the perfect family doctor. He makes no attempts to specialism, but is ready in all emergencies. In surgery, obstetrics, in skin diseases, in fact, in any department he must be ready to act without consultation. And while he must succeed in all branches of surgery, he is also successful, as a rule, in internal medicine. There are few such men who can fill all these requirements, but the type serves to show the difference between the city and the country physician. But men who are so successful rarely stay in the country. Like Sims, Agnew, Goodell, and others, they soon find their way to the large cities where they make their mark.

The greatest objection to the country doctor is that, as a rule, he takes a short course in medicine, and then is launched upon his field of labor without any further experience. The city doctor has the advantages of medical societies and intercourse with colleagues and post-graduate experience, while the country doctor has to exercise his own ingenuity, and it is in the constant exercise of his own natural resources that his education is completed. It is this habit of self-reliance that makes him such a capable man, but he also may become too conceited and have too much self-esteem and self-possession. Then, in a small place there are the effects of social surroundings and professional jealousies which are more felt than in the large cities. The city and country doctor are supposed to be alike at the start, but the city doctor soon leaves the country one far behind. There is one way in which the facilities of the country doctor might be improved, and that is by the establishment of cottage hospitals throughout every community. Then again, the country doctor should take a post-

graduate course at the end of his fifth and his tenth year, and nothing should ever prevent his doing this. The county medical society should also be cultivated and the meeting never be missed. The country doctor should also belong to the State society, and this he should consider important second only to his own county society.

The want of books and the absence of hospitals is a great drawback to the country doctor. This could be, in part, prevented in Maryland by the State Faculty library. The country physician hesitates to read a paper before the city society on account of the critical audience. Educational clubs in country districts can help to enlighten and instruct the country physician, and books could be distributed by means of the cottage hospitals, and if there are no such hospitals, then the drug stores may be used as centers. There are nearly four hundred such cottage hospitals in Great Britain, a few in New England, and none in Maryland or the South. In the cottage hospital the country doctor can gain a certain amount of experience in exhibiting and in studying the various cases. He can perform a certain number of autopsies and have the advantage of using the microscope. The first hospital that was established in England was in 1853. There were no trained nurses at that time, but they have become very important now. There is very poor nursing in the country districts. The nurse not only helps the doctor, when in attendance with him, but she acts as subsidiary physician, and pays visits when he can not come. She should be an adaptable woman of good moral tone.

Some say that it would be very difficult to establish such hospitals, but in Maryland with the aid of the Faculty it would not be at all difficult. Assistance could be had from the State treasury, from the County treasury, from private subscriptions and from various organizations. The county medical officer could also act as bacteriologist and pathologist. Thus could be formed a kind of medical society. It would be a sort of university extension teaching, as it were. It would cause a great addition to the membership of the Faculty, and would be a power to command respect to their demands.

Dr. WM. S. GARDNER then read a paper entitled "The Vaginal Operation for Extra-Uterine Pregnancy." He related a series of cases, and showed that while these operations were not at all easy and that the number of cases reported were very small, still the success has been favorable, and it was evident that this was a very practical method of treating extra-uterine pregnancy.

Dr. H. A. KELLY said this matter was extremely important, and that it was one of the more serious and dangerous operation, but when properly done saves the woman from unnecessary mutilation. The operation as formerly done was to tie up the vessels and thus ward off the danger from hemorrhage. Another way was to open the cavity through the posterior vaginal vault, clean out the clots and thus save the patient. But there should be one word of caution to surgeons who do this operation. They must be prepared to open the abdominal cavity and take out all the structures necessary. All of his cases got well but one.

Dr. THOS. S. CULLEN spoke of the "Pathology of Endometritis." This inflammation of the uterine mucous membrane occurs in the acute and chronic stage. The histologic appearance of the epithelium covering the mucous surface is composed chiefly of large nucleated leucocytes: the epithelium is swollen and somewhat distorted. The uterine glands may be normal in part but the mouths of the glands are very much swollen, and there are many pus cells present. In chronic endometritis the mucous membrane is highly granular and has an appearance like polypi. Between the acute and the chronic stages are all transitions. The term granular endometritis is highly improper and should be abandoned. Endometritis is supposed to be very frequent but he has found only forty-nine cases in 1800 gynecologic cases at the Johns Hopkins Hospital. The treatment consists in dilating and curetting the uterus. Dr. Cullen exhibited several drawings.

Dr. HOWARD A. KELLY said that endometritis was exceedingly rare, about only one case in fifty that go to the clinic being really endometritis.

Dr. WM. H. WELCH said that some considered chronic endometritis very common and some rare. It is not uncommon to have variation in the number, shape and size of the uterine glands, and it is not right to call this endometritis even if it is clinically so. These scrapings are not normal, but they are irregular in shape and size and there is a sort of hyperplasia. There are cases with actual change in the stroma with hyperplasia of the stroma cells. As to the value of microscopic diagnosis of the scrapings, this is particularly of value in cancer. Many physicians are careful in risking a diagnosis in examining these scrapings. The negative results do not necessarily

convince us, but experience has shown that cancer cells will usually show themselves in the scrapings.

Dr. B. B. BROWNE said that many cases of so-called endometritis got well after curetting, and we did not know what they were until the scrapings were made, that is, we do not make the diagnosis until they have been treated by scraping, so that the diagnosis does not make much difference.

Dr. CULLEN said, in conclusion, that he agreed with what Dr. Welch said; in his cases and a study of specimens found, the scrapings and specimens were hardened in different fluids.

Dr. W. W. RUSSELL then read a paper on "The Treatment of Tuberculosis of the Uterus and Fallopian Tubes," and said that the principal work had been done by Dr. J. Whitridge Williams of Baltimore. He said there were two forms of tubercular salpingitis, one in which the disease is found in the abdominal cavity and in the tubes, and the other in which it is found in the tubes, while the abdominal cavity is not necessarily affected. He had no cases of the first sort and twelve of the second. The uterus is found to be tuberculous in every case in endosalpingitis. If the disease is limited to these organs then the affected tissues should be removed, and the patient's general condition should be looked after, but if tuberculosis is in other parts of the body then it is useless to operate, and when there is dropsy and other symptoms, operation is not necessary. He then spoke of the various methods of removing the ovaries and the manner, whether by the abdominal or the vaginal. By the latter the dissection should be made carefully. He then described the operation in detail. He said that few cases are recognized soon enough to be operated on, and this is true in many of Williams' cases. Diagnosis is made in about one-half of 1 per cent.

Dr. HOWARD A. KELLY then read a paper entitled "Treatment of Fibroid Uteri." He said that rapid strides had been made in doing this operation, and it was but a little while ago that we hesitated to take out these tumors. This operation has gone through several stages in the last fifteen years, for at that time they were removed in a very haphazard way. The abdomen was opened, the uterus was pulled out, the peritoneum was sewed down around the uterus and pinned to it and the stump was left to mummify and slough off. Schroeder, of Berlin, urged us to treat this by creating a pedicle and dropping it back into the cavity with the result of a large mortality from sepsis. Futsch of Breslau, and Kelly of Baltimore, were the first to do the operation in the more modern way to avoid sepsis and hemorrhage. They stitched the peritoneum around the uterus. About this time, Stimson of New York suggested ligating the four sources of blood supply, and after tying these vessels the stump could be dropped back, and there was no sepsis. The technique is important and so is the time. It used to take from one-half to one hour to complete this operation, and then often the patient died. It was necessary to break up the adhesions and tie the vessels, but now the operation can be done in three minutes and the mortality should not be more than 3 or 4 per cent. He referred to two young women who had fibroid tumors, who were both engaged to be married, on which he had operated with success. He bases his remarks on an experience of ninety-one cases. He took out the tumors in these cases and left the uterus, and undoubtedly this can be done in nearly all cases, especially with women in the child-bearing period. He had four deaths in these ninety-one cases, but none in his experience became pregnant afterward. He wears gloves, uses gauze, and looks out for hemorrhage. He urges conservatism in the treatment of these cases, and also as to any operation.

Dr. THOS. S. CULLEN said that one of these cases which died was through his fault and not Dr. Kelly's. In one case which Dr. Kelly operated on she had had four miscarriages. He never does a myomectomy if he finds any evidence of sepsis in the tubes.

Dr. B. B. BROWNE then read a paper entitled "The Removal of Submucous and Intra-Uterine Fibroid Tumors by Enucleation and Traction," in which he mentioned a series of cases and showed results.

SECOND DAY—MORNING SESSION.

The minutes of the previous meeting were read, corrected and adopted, and fifty-two new members elected.

Dr. JACKSON PIPER then read a paper on "Interstitial Pneumonia," in which he related three cases, tending to show that: 1. Interstitial pneumonia, the result of acute pneumonia, is amenable to treatment even after some months' duration; 2. That a consolidation under the second day will terminate either in gangrene or consumption. His conclusions were that it was never well to leave a patient with unresolved pneumonia until all remedies had been tried.

Dr. J. E. GICHNER then made some remarks on
STATE SANITARIA AS A MEANS TO DIMINISH THE SPREAD OF
TUBERCULOSIS

and said that the cause of disease is distributed by the consumptives, and that there is no place in Maryland where patients can be exclusively treated and taught how to live. Many cases get well without suspecting infection and the patient tends to recover when given the opportunity to create resisting tissues, and this tends to explain the many cases of recovery. He thought the best results of our labors to cure the disease were to prevent it. Physicians should be sanitarians. There should be a State sanitarium where patients should be treated properly.

Dr. WM. B. CANFIELD said he thought that one point which Dr. Gichner made was especially good, i.e., that patients tended to get well when given the opportunity to create resisting tissues. He had been connected with a small hospital for the treatment of consumptives in the city of Baltimore, and had noticed a marked improvement in cases which had received no medicine, but only food. This hospital is supported entirely by private contributions and receives no city or State aid. There had been treated in the last two years, forty-two cases, and of these, probably one dozen had so far recovered that they were able to return to their former occupations. This hospital is for the treatment of incipient cases only and he would be glad to have physicians throughout the city and State, who had cases of early tuberculosis, notify him and they would receive free treatment.

Dr. GICHNER said in reply that he had purposely not mentioned this institution because of its being a private one and being situated on a dusty street where cars passed, and not in accordance with his ideas.

Dr. JOHN RUHRAER then made a report of

A YEAR'S WORK IN THE PREVENTIVE TREATMENT OF RABIES.

He said that in the year past, at the Pasteur Institute of the College of Physicians and Surgeons, thirty-five cases had been treated, with no deaths. He was glad to say that the Germans had taken up the Pasteur treatment. Statistics of this institution would be issued yearly. He had divided his cases into three classes: Those bitten by animals which were undoubtedly rabid and proven so by inoculation experiments; those bitten by animals whose condition has been verified by a competent veterinarian; and those bitten by animals which are said to be rabid by others than veterinarians. His cases were principally from the first and third classes. Then it is necessary to classify the cases according to the position of the bite, as to whether the animal bit through the clothing or into the skin directly. If cauterization is to do any good it has to be done within the first half hour, and when done an hour or more later it is perfectly useless. The actual cautery or a hot iron will suffice. Nitric acid is the best chemist agent; nitrate of silver is perfectly useless, yet many physicians use this. There seems to be a great prevalence of rabies in Baltimore and surrounding counties. It seems to occur periodically among animals from time to time. Of the thirty-five cases treated, twenty-five were bitten by animals that were proved to be rabid afterward, and ten by animals so suspected. He then compared his statistics with those of other institutions.

(To be continued.)

Tennessee State Medical Society.

The Sixty-fifth Annual Meeting, held at Jackson, Tenn.,
April 12, 13 and 14, 1898.

FIRST DAY.—MORNING SESSION.

The session was opened with prayer by the Rev. G. T. Sullivan, pastor of the First Methodist Church, Jackson.

The first paper read was on the

HYGIENE AND MEDICAL SUPERVISION OF PREGNANCY,

by Dr. J. H. Preston of Humboldt.

He believes it to be the duty of the husband to early acquaint his physician that his wife is enroute and place her under his supervision. Under normal conditions there might be little or nothing for the physician to do but give instruction regarding general hygienic regulations. But under our modern social regime, which is so full of various dissipation, he will sometimes have his hands full in getting instructions carried out. One of the greatest difficulties is in the matter of dress. A great many women are so loath to give up their social relations that they will persistently dress in a manner that is highly deleterious. Some will lace themselves in an attempt to hide their condition, as though their prospective maternity were a crime or disgrace. Moreover, some pregnant women immerse

themselves from all out door exercise and fresh air and thus become victims of lassitude, rendering themselves unfit for the ordeal toward which they are tending. The prospective mother should have loose but comfortable fitting garments of medium weight, suspended mostly or entirely from the shoulders, without corset unless it be one especially provided for the pregnant condition. Many complications arise during pregnancy and at time of delivery because of improper dress, which may also have its influence in faulty development of the fetus. We should have a happy cheerful woman during pregnancy to expect a happy uncomplicated delivery of a healthy baby and a safe passage through the puerperal state. Maternal impressions affect the exterior of the fetus as well as its mental organization. The wise physician should aim to direct the mind of his patient as well as her physical welfare. Almost any disease may supervene in the course of gestation, thus engendering a grave complication, or pregnancy may occur and often does in spite of some chronic or inherited disease. Pregnancy may be the exciting cause which arouses some latent disease or predisposition to disease into activity. Besides, there are a number of disturbances that might be termed physiologic phenomena, such as the vomiting of pregnancy, neuralgia of the teeth independent of caries, cough and dyspnea. One of the most fatal diseases in the pregnant state is pneumonia, which can almost always be avoided by proper hygienic care. Diseases of the urinary system call for intervention perhaps oftener than any other class of troubles. Irritability of the bladder and dysuria occur often in first pregnancies, while incontinence is met with more frequently in later pregnancies. Retention of urine in pregnancy is sometimes a very grave accident. It may be attributed to reflex contraction of the neck of the bladder when met with early in pregnancy, but it is most frequently met with as a symptom of retroversion at about the fourth month, or later as a result of cystocele. But the renal function requires most care in the pregnant woman. Four forms of renal disease may be met with in pregnant women, viz., acute and chronic parenchymatous and interstitial nephritis, and a special form peculiar to pregnancy—pregnancy kidney or pregnancy nephritis. The last begins and ends with the pregnant state. The symptoms are edema and albuminuria. The course is usually favorable but eclampsia may supervene with sudden increase of albumin and dropsy with lessened excretion of urine. Acute nephritis may cause eclampsia, but it rarely occurs in the chronic form. For grave albuminuria the absolute milk diet is the best treatment. External palpation of the abdomen after fetal viability may give some information regarding the position of the fetus or multiple pregnancy. Every woman in her first pregnancy, or who has had special difficulty in a previous parturition, should be examined by external and internal pelvimetry about the seventh or eighth month. If the labor promises to be long, painful or difficult from obstruction of any kind, the obstetrician ought to know it in advance that he may elect at a proper time before parturition whether to choose the induction of a premature labor, to depend upon the use of the forceps or to resort to podalic version, symphyseotomy or a Cesarean section and thus avoid craniotomy. Often we are asked if there is no means of making child-bearing easier. The essayist had attended women who had used preparations advertised for this purpose, but had not seen any benefit.

The paper was discussed by Drs. J. S. Nowlin of Shelbyville, T. J. Happel of Trenton, Dr. Forshay, J. F. Griffin of Crona-ville and Dr. Preston.

TWO CASES TREATED BY SODIUM INFUSION,

was a paper presented by Dr. W. F. ROCHELLE, Jackson. In the first case there was a temperature of 104 to 105 degrees with heart failure, loss of consciousness and other symptoms of impending death. A quart of saline infusion was injected into the veins and the pulse soon became full and quiet, dropping from 190 to 136 within half an hour. In a few hours consciousness returned and the patient recovered in the course of two weeks. The second case was that of a patient who had suffered about two years with diabetes. The symptoms of diabetic coma supervened. Hereupon some saline solution was injected into the cellular tissues with apparently no benefit. The same solution was then introduced into the veins. The pulse, which had been weak and compressible, became full and strong. The coma disappeared. This continued for three or four hours, when the injection was repeated with the same good result. The injections were continued at intervals of four to six hours for about two days, when the effect gradually failed, the patient grew weaker and died. The subject was discussed by Drs. D. J. Roberts of Nashville, J. B. Cowan of Tullahoma, Miller, J. L. Crook of Jackson, T. J. Happel of Trenton, J. A. Crook of Jackson and the essayist.

Upon motion the Society adjourned until 1:40 p.m.

AFTERNOON SESSION.

"The Pathology and Differential Diagnosis of Intestinal Obstruction," by Dr. RICHARD DOUGLAS of Nashville, was discussed by Drs. Deering J. Roberts of Nashville, W. K. Sheddan, Williamsport, W. D. Haggard, Jr., of Nashville, and by Dr. Douglas.

"Fever, Just Fever," by Dr. D. J. ROBERTS of Nashville, was a description of the peculiar continued fever found especially in the south, which is neither malaria nor typhoid fever, although resembling somewhat these diseases. The paper was discussed by Drs. J. A. Crook of Jackson, Witherspoon of Nashville, J. L. Crook of Jackson, T. J. Happel of Trenton, J. B. Cowan of Tullahoma, J. S. Nowlin of Shelbyville, W. F. Clary of Bellbuckle, W. K. Sheddan of Williamsport, J. D. Hopper, J. F. Griffin of Cronanville, and Roberts.

A PLEA FOR THE CONSERVATIVE MANAGEMENT OF UTERINE INFLAMMATIONS AND DISPLACEMENTS.

Was presented by Dr. I. A. McSWAIN of Paris. He said: Tubercular and syphilitic infection, rheumatic and gouty conditions, general debility and anemia, may be predisposing causes of diseases and displacements of the uterus. The displaced womb may be only a part of a vast hernia of the pelvic viscera making a decent in various degrees through the pelvic outlet. Dilatation of the stomach, hepatic and splenic enlargements, the growth of tumors or constipation, may contribute to these troubles. The demands of modern society, dresses, lacing, the uncomfortable load of skirts fastened around the waist are a fruitful source of uterine disorders. But by far the greater number of these cases owe their origin to negligence or ignorance during parturition or to exposure and bad treatment succeeding labors and abortions, non-observance by the attendant of the rules of antiseptic midwifery, failure to recognize and immediately repair injuries of the birth canal or perineum, and gonorrhea. Subinvolution is more often an effect than a cause. Frequently the puerperal woman gets up too soon after delivery and assumes her household duties, thus exposing her womb to many sources of infection. A flexed womb or one retroverted is in no position for drainage, and by retention of secretions provokes or perpetuates an inflammatory process.

By an examination we should ascertain the presence or absence of inflammatory disorders, the condition of the perineum, the tenuity of the vaginal walls, whether there has previously existed pelvic inflammations, and if so, the nature and extent of the exudates or adhesions, the presence or absence of pregnancy, the size of the uterus, the length of the cervix, the condition of the ovaries, tubes and ligaments, whether there be any displacement of the organ, and if so the direction and extent, also whether the flexion, prolapse or version be due in whole or in part to the presence of tumors or enlargement of any other abdominal organ or is accompanied with prolapse or displacement of the bladder, vagina, rectum or kidney, also whether there be fistulous openings, cervical rents or abrasions, ulcers, excoriations or cancer.

In the treatment of malpositions and inflammatory processes of the uterus we should reduce existing inflammation and overcome if possible the resulting evils and restore the womb to its normal position in the pelvic cavity. The first essential is rest. The patient should be put to bed and kept quiet in both body and mind. This is especially required in all acute cases. The second essential is cleanliness, which implies antiseptic precautions on the part of the physician and nurse, bed and surroundings. The disease must then be treated much as you would any sore, that is, cleanse it. If the os is not sufficiently patulous, it should be dilated with a steel dilator and under an anesthetic, every particle of foreign substance should be removed with a curette. Then thoroughly irrigate the uterine cavity with sterile water containing a proper percentage of one of the non-toxic antiseptics. Bichlorid of mercury or carbolic acid, if used at all, should be greatly diluted. Lysol, creolin, permanganate of potash, hydrogen dioxid in proper solutions, or the compound tincture of iodine, one ounce to the quart of water, are all admirable preparations for this purpose and are free from danger. Not every case will require the curette, but there are few, if any, cases of endometritis that do not require thorough irrigation. Having cleansed the organ local applications are in order. Perhaps one of the best combinations is equal parts of the compound tincture of iodine, glycerin and witch-hazel, or carbolic acid and tincture of iodine. Among the newer preparations eucrophen and aristol suspended in alcohol have a soothing and antiseptic effect. There may be cases in which fuming nitric acid or chlorid of zinc is needed, but such cases are few and milder preparations should have preference. The third important step is drainage, which may be accomplished

by inserting a drainage tube or a strip of gauze. An important step in securing drainage is to straighten the canal of the uterus. To this end all malpositions should be corrected. This is best accomplished by the use of tampons of prepared wool, which should be saturated with a solution of boracic acid in glycerin and ichthylol and inserted under the fundus, after having raised it from its abnormal position. The woman should then be placed in bed and not disturbed for thirty-six or forty-eight hours, when the wool should be removed, the vagina and uterus again irrigated and the packing replaced with fresh material. Persistence in this course will overcome the ordinary acute cases. The more chronic cases may require in addition massage, electricity, a repetition of curettage and various constitutional measures. In chronic cases with plastic exudation or where the uterus is large and heavy depleting measures are indicated. Hot vaginal douches must be used. Tampons of wool saturated with boracic acid or glycerin should be packed in the vagina and allowed to remain twenty-four hours, followed by hot vaginal irrigation, and the renewal of the packing day after day will hasten resolution of exudates, reduce the size of the womb and materially assist in restoring the parts to a normal condition. One of the best laxatives to secure daily evacuation of the bowels in cases of constipation is equal parts of sulphur, bitartrate of potash and sulphate of magnesia. After having reduced inflammation and its sequelae and having secured absorption of exudates and the loosening up of morbid adhesions, the uterus may be placed in its normal position and retained by means of a well-fitting pessary. This does not always cure the misplacement, neither ventrofixation nor Alexander's operation. In cases where there are rents in the cervix or perineum repair is indispensable.

The paper was discussed by Drs. T. J. Happel of Trenton, Richard Douglas of Nashville, and by the essayist.

ULCER OF THE STOMACH

Was presented by Dr. J. T. Altman of Nashville. He said: Statistics show us that at least 5 per cent. of all autopsies reveal either an open gastric ulcer or the cicatrix of one that has healed. The etiology of ulcer of the stomach is not very clear, but there are three factors which enter into its production, viz., a local disturbance in the walls of the stomach, whether this be simply nutritional or due to trauma, an embolus or a thrombus; a hyperacid gastric juice, and a diminished alkalinity of the plasma of the blood. Age, sex, locality, occupation, corrosive poisons and alcohol are predisposing causes. The main diagnostic symptoms are pain, vomiting, tenderness on pressure and hematemesis. It is estimated that about 6 per cent. of all cases result in perforation. This is more frequent and fatal when the ulcer is in the anterior wall of the stomach. The differential diagnosis lies between ulcer and chronic gastritis, gastralgia, hepatic colic and cancer of the stomach. When ulcer is suspected put the patient to bed, keep him absolutely quiet and withhold all food from the stomach. Allow no food in the stomach for several days. In the meantime resort to rectal alimentation. Put only albuminous food that has been previously converted into peptones in the stomach at first, so that absorption will take place easily and rapidly and render the physiologic peristalsis and secretion of acid unnecessary. Milk that has been previously peptonized is the ideal food at first. But as this has a bitter taste it soon becomes repulsive, when we may give fresh milk with lime-water or some other alkali. By the end of the second week we may add egg albumin in the shape of raw eggs. In the third week soft boiled eggs with well toasted bread soaked in milk. Thirst is relieved by crushed ice. By the fourth week, if there is no pain or vomiting, raw beef steak finely scraped and raw oysters without vinegar is permitted. From this time a gradual return to a light mixed diet is allowed, but care must be taken for a long time not to eat coarse articles.

Next to rest and diet in importance comes lavage. This is of benefit to relieve the associated gastritis but must be used with caution, taking care never to over-distend the stomach, for by so doing we separate the edges of the ulcer, the granulated tissue is broken down and cicatrization is prevented. Also there is danger of inducing hemorrhage or perforation, unless care is taken to introduce a limited amount and see that it is all carried out. We scarcely ever see a case in which opium is not indicated at some time either to control pain or some complication. The diminished alkalinity of the blood and the excessive acid in the stomach call for the administration of alkalis. Bicarbonate of soda in twenty grain doses before taking food or when in pain acts admirably. Subnitrate of bismuth in half drachm doses also serves a good purpose. Carlsbad salt fulfils the same indications and at the same time keeps the bowels open.

When hemorrhage occurs the patient should be placed in the

recumbent position with the head low. Give morphia and atropie hypodermatically to quiet peristalsis, ergotin to contract the arterioles: apply an ice-bag to the epigastrium. In severe cases apply a ligature around the leg and arm. If collapse is marked inject saline solution into the veins. Perforation demands immediate operation.

As soon as cicatrization is fairly established the existing anemia should be combated by the milder preparations of iron. Three months are usually required for complete cicatrization. Even then relapses may occur.

The subject was discussed by Drs. J. B. Cowan of Tullahoma, J. A. Witherspoon of Nashville, Savage of Nashville, and Dr. Altman.

EVENING SESSION.

The address of welcome, which had been deferred until this time, was delivered by the Rev. C. H. STRICKLER, D.D. This was responded to by Dr. D. J. ROBERTS of Nashville, the Vice-president for Middle Tennessee.

Next in order was the President's address: "The Relation of Public Morals to Public Health," by Dr. T. K. POWELL of Dancyville.

SECOND DAY—MORNING SESSION.

The first paper of the day was "Puerperal Mastitis," by Dr. C. N. SEBASTIAN of Martin. This was discussed by Drs. T. J. Happel of Trenton, J. B. Murfree of Murfreesboro, J. B. Cowan of Tullahoma, J. A. Witherspoon, D. J. Roberts, J. S. Cain and Richard Douglas of Nashville.

"Observations in Electrotherapy," was presented by Dr. G. P. EDWARDS of Nashville, and discussed by Drs. Cross, Gillespie, Douglas, Griffin and Edwards.

Dr. S. R. MILLER of Knoxville, read a paper on

TRANSFUSION.

The essayist believed intravenous transfusion the quickest and most accurate. It requires more skill than the other methods and more attention to the details of asepsis than the subcutaneous injection or enema, but is to be preferred where there is immediate demand and the necessary preparation is made. It combats shock best. It is perhaps most useful in very bloody operations where otherwise the necessary loss of blood would prove fatal before the operation could be completed. The subcutaneous method is slower and requires less preparation and skill than the intravenous method. It does not depend so largely upon asepsis and should be employed where the intravenous method is not practicable. The introduction of fluid into the peritoneal cavity should be employed only in operations involving that cavity. It is probable that this may prevent to a small degree adhesion of the raw surfaces. Rectal injections are easiest and quickest of application. The essayist prefers this method for the purpose of avoiding rather than to combat shock. It serves best where there is least shock. The general surgeon should not allow himself to become "wedded" to any particular method but should in each instance employ the one best suited to the individual case and its environments.

The subject was discussed by Drs. J. L. Crook of Jackson, J. S. Cain of Nashville, I. A. McSwain of Paris, D. J. Roberts of Nashville, Jelks and Miller.

"Illustrative Specimens of Perforative Appendicitis, Carcinoma Uteri, Gall Stones and Fibroid Tumors of the Uterus," were presented by Dr. W. D. HAGGARD, Jr., of Nashville. The specimens were discussed by Drs. Richard Douglas of Nashville, T. J. Happel of Trenton, W. K. Shedd of Williamsport, J. B. Cowan of Tullahoma, J. A. Witherspoon of Nashville, Jelks of Memphis, J. S. Cain of Nashville, D. J. Roberts of Nashville, and Dr. Haggard.

AFTERNOON SESSION.

"Gunshot Wounds of the Abdomen" was a well rounded paper by J. B. MURFREE of Murfreesboro. He advised operation (laparotomy) and the repair of the injury done. The subject was discussed by Drs. W. K. Shedd of Williamsport, Nealy of Memphis, J. B. Cowan of Tullahoma, Richard Douglas of Nashville, and Dr. Murfree.

Election of officers resulted as follows: President, T. H. Marable of Clarksville; vice-president for Middle Tennessee, W. C. Bilbro of Murfreesboro; vice-president for West Tennessee, V. A. Biggs of Martin; vice-president East Tennessee, T. W. Gallion of Dandridge; secretary, W. D. Haggard, Jr., of Nashville; treasurer, D. E. Nelson of Chattanooga.

Next place of meeting, Nashville.

A paper on "Castration for Reflex Neuroses Following Mumps, with Report of Case," was read by Dr. J. S. NOWLIN of Shelbyville, and discussed by Drs. J. Roberts of Nashville, J. A. Crook of Jackson, Griffin and Nowlin.

A paper on "Some of the Causes of Unsuccessful Treatment as Ordinarily given for Chronic Suppurative Otitis Media," was presented by Dr. L. B. GRADDY of Nashville. Upon motion the discussion of the paper was deferred until the evening session.

EVENING SESSION.

The first item of the program was the discussion of Dr. Graddy's paper, which was participated in by Drs. J. T. Heron, Smith, Savage, Goltman and Graddy.

Dr. JOHN L. JELKS of Memphis, gave a "Report of Surgical Cases," which was discussed by Drs. Happel, Gillespie, Nealy and the essayist.

PREVENTION AND TREATMENT OF INJURIES TO THE PARTURIENT CANAL

Was presented by Dr. J. T. REDDICK, an invited guest from Paducah, Ky. The paper dealt only with lacerations of the cervix and lacerations of the pelvic floor. Many of the injuries to the parturient canal may be averted by proper attention before and during labor. The urinary organs and bowels should be placed in a healthy condition before labor. Everything done to put the pregnant woman in a normal healthy condition will in a measure prevent lacerations of the cervix and perineal floor. Sedentary and indolent habits, pelvic and perineal irritations, or anything which may impair the nutrition of the pelvic floor, renders it irritable, soft and predisposed to rent. Fashionable women who live indoors, lace tight and wear improper dress, are enervated and are predisposed to lacerations of the pelvic canal. On the other hand, precipitate labors in strong, muscular women, with violent uterine contractions, especially if there is a medium-sized child and a rigid perineum, may rupture the pelvic floor. This may be avoided by complete anesthesia with chloroform. Lacerations may be frequently avoided by supporting the perineum during the second stage of labor, especially if there be a vertex presentation. An overloaded rectum and distended bladder, improper traction in forceps deliveries and the use of ergot, may produce lacerations of the pelvic floor. Hence the obstetrician by personal attention to many little things before and during labor may prevent injuries to the parturient canal. But lacerations do occur with the best physicians and surgeons, and extremely unfortunate is she who has received such lacerations and her attendant is unable or too negligent to detect them and give them prompt and competent surgical attention. Lacerations may be often detected by the educated finger, but to be doubly sure that there are no injuries an ocular examination should be made at once. In laceration of the cervix immediate operation is either one of election or strict necessity. Immediate operation becomes a necessity if the laceration involves the circular artery and the hemorrhage is alarming. Hemorrhage could be controlled by tampons, but the danger from sepsis would be greater than from an operation. Many cases of laceration of the cervix heal spontaneously, especially if the course of puerperium is aseptic, and for that reason the essayist deems it advisable to postpone the operation when possible.

The most important lesions to the parturient canal perhaps are injuries to the pelvic floor. The long train of symptoms which may follow a lacerated perineum, namely, hemorrhage and collapse, infection through an open wound, puerperal septicemia, a tedious and incomplete convalescence, subinvolution, endometritis, uterine displacements of different kinds and degrees, prolapse of ovaries, tubal disease, rectocele, neuralgia, functional derangement of adjacent and remote organs, and innumerable reflex troubles and hysteria, is a living monument to the incompetency of the medical attendant on such cases. About the only contra-indication to an immediate operation is exhaustion of the patient from prolonged labor or post-partum hemorrhage. Where the laceration is slight and requires but a few stitches, anesthesia is generally not required, as the sensibility of the parts is greatly diminished from the pressure associated with delivery. If the laceration is extensive it is best to administer an anesthetic to enable the physician to operate with care and save the woman unnecessary pain. The essayist entered into a description of the operations for the repair of lacerations of the cervix and of the perineum. The paper was discussed by Drs. G. B. Gillespie of Covington, J. L. Jelks of Memphis, T. K. Powell of Dancyville, and J. A. Crook of Jackson. It was then moved that the discussion be continued the following morning.

THIRD DAY—MORNING SESSION.

The session was opened with prayer by the Rev. Dr. Matthews.

The first order of business was a continuation of the discussion of Dr. Reddick's paper, which was taken part in by Drs. I. A. McSwain of Paris, Goltman of Memphis, W. D. Haggard, Jr. of Nashville, T. W. Gallion of Dandridge, Wm. Krauss of

Memphis, Yarbrough, E. W. Ridings of Dixon, Smith, W. K. Sheddan of Williamsport, J. F. Griffin of Cronanville, Jelks of Memphis, W. F. Clary of Bellbuckle, T. K. Powell of Dancyville, and Dr. Reddick.

A SIMPLE METHOD OF ESTIMATING THE SPECIFIC GRAVITY AND HEMOGLOBIN PERCENTAGE OF BLOOD

was demonstrated by Dr. WILLIAM KRAUSS of Memphis. The essayist had constructed a pipette graduated in hemoglobin percentages and used two fluids, one of 1000 sp. gr. at 60 degrees F. and colored with gentian violet, the other of 1060 at 60 degrees F. and uncolored, which would float blood up to 110 per cent. hemoglobin. The specific gravity of the two fluids is sufficiently alike to give uniform variations for temperature, and thus eliminate the temperature error without requiring calculation. The pipette holds 5 c.c. at the 110 mark. This quantity of the clear fluid is measured into a test tube. A drop of blood is then floated on it. The pipette is filled with the violet mixture and introduced to the bottom of the test-tube and then allowed to discharge its contents which will rise in the fluid, being lighter, and can be seen by its color to diffuse itself in the clear mixture. As soon as the blood begins to recede from the surface, the additions are interrupted until the proper specific gravity is obtained. The hemoglobin percentage can then be read off from the pipette.

The paper was discussed by Drs. J. B. Cowan of Tullahoma, Max Goltman of Memphis, and Dr. Krauss.

"Report of Six Amputations for the Relief of Osteo-myelitis Following Severe Ulceration of the Leg," was presented by Dr. M. GOLTSMAN of Memphis, and discussed by Dr. J. L. Crook of Jackson, and by the essayist.

The list of delegates to the AMERICAN MEDICAL ASSOCIATION was then read by the Secretary.

PRACTICAL NOTES.

To Abort Erysipelas.—Lobit uses a 10 per cent. iodoformed or iodoled collodion, with which he has cured twenty-five cases within three to four days.—*Sem. Méd.*, March 30.

Adhesivum is a thick, reddish, aseptic fluid which hardens rapidly in contact with the air and is then insoluble. Poured on a wound it forms a tenacious crust, uniting the lips of the wound and protecting it like a scab.—*Aerztl. Polytech.*, 1897, December 8.

The Success of the Impermeable Alcohol Vapor Compresses is confirmed by Lanz, who has not only cured a number of dermatoses with them, sycosis, acne, buboes, etc., but also reports a case of cutaneous tuberculosis completely cured.—*Sem. Méd.*, April 13.

Orthoform Combined With Arsenious Acid.—The application of arsenious acid in the treatment of epithelial cancer, which Cerny and Trunczek have found so effective (*vide JOURNAL*, xxix, page 83), can be rendered painless by adding an equal amount of orthoform.—*Sem. Méd.*, April 13.

Chloroform Applied to the Abdomen to control spasmodic contractions of the uterus intrapartum. The abdomen is painted with a mixture of one part chloroform to two or three parts olive oil and an air-tight covering applied over it, when the uterine contractions promptly lose their spasmodic character. *Sem. Méd.*, April 13.

Ventilated Shoes.—The disadvantages of the usual close moist leather shoes are obviated by Dr. Spener of Berlin, who has an ornamental design cut through the leather in the upper part of his shoes, to within an inch of the sole. The lining is of duck the same color as the leather and the delicate open work is not noticeable, while the shoe is practically as waterproof as before.—*Deu. Med. Woch.*, April 7.

Salt Solution in Infantile Broncho-pneumonia.—The injections are followed by an increase in the arterial tension, the heart is relieved, the temperature falls gradually or abruptly, and all the natural excretories seem to "feel the whip." Ausset agrees with Lépine that these injections stimulate phagocytosis, which explains their action in these cases.—*Nord Méd.*, April 1.

Glycerin Tampon for Inducing Premature Labor.—Wienskowitz carried to a successful termination a case of deformed pelvis in which a previous confinement had resulted in partial rupture of the uterus. A strip of gauze 75 by 1 cm. was dipped in glycerin until it had absorbed 15 c.c. and then introduced into the cervical cavity. Labor pains came on gradually and after thirteen hours the child was delivered alive, thirty-fourth week.—*Sem. Méd.*, March 30.

The Value of Ichthyol in Tuberculosis as a symptomatic and adjuvant of hygienic measures is confirmed anew by Combe-male, who has completely cured with it one case of "rapid consumption" and has used it with marked benefit in 120 cases of tuberculosis in the last year, in different stages. It is most effective in the torpid forms, and is counter-indicated and sometimes injurious where there is erethism or fever. It stimulates the appetite, favors the nutritive processes, reduces the cough and builds up the general health, while locally it is an efficient disinfectant. With one to two grams a day the sputa are liquified and disinfected; drying up with larger doses. It is usually administered in pills or capsules just before meals, one to three grams a day, suspended for a while, or combined with two to five grams dermatol if it produces diarrhea, as occasionally occurs.—*Nord Médical*, April 1.

The Technique of Gastrostomy has been so perfected of late that E. Fergue urges not to wait for depressing inanition in fibrous or cancerous constrictions but to make the "gastric mouth" promptly and sustain the patient's strength. He has some cuts in the *Presse Méd.* of March 23, showing two plump individuals placidly feeding themselves milk through the tiny gastric aperture. The gastric mucosa is brought out and sutured to the wound, thus bringing only the lining of the stomach into contact with gastric juice and preventing possible corrosion. The opening is only large enough to admit a 12 or 14 Nélaton sound, which is withdrawn after meal times, when the folds of the mucosa protrude spontaneously closing the "mouth." By operating promptly the patient is saved from possible "Schluck pneumonia" from aspiration and regurgitation of the contents of the stomach, which find their way into the respiratory organs and are a frequent cause of fatal pneumonia in cases of cancerous constrictions. The "mouth" can be used to supplement the usual methods of feeding, and can be readily closed whenever it ceases to be needed.

Restitution of the Posterior Portion of the Urethra With the Soft Parts of the Perineum.—C. A. Ljunggren describes, in the *Nordiskt Med. Arkiv*, 1898, No. 1, his success in two cases of traumatic rupture of the urethra, one recent the other old, with a stricture, abscesses and fistula, resulting from a fall astride a beam. In both there was a gap of several centimeters, which he filled by substituting the soft parts of the perineum sutured around a permanent sound and drained. The sound was removed in twenty-four to thirty days: the urethra healed with a new mucous membrane lining and normal functions and no signs of a recurrence of the stricture since; four and one-half years in the last and two in the first case. He recommends removing all the diseased tissue, leaving a bridge of the urethral wall whenever possible, as it not only hastens the formation of new tissue, but prevents the stumps spreading farther apart, taking stitches also in the extra-urethral tissues. Guyon does not drain even in the infected cases, but Ljunggren considers it better technique to drain for a day or so, while the tissues are most sensitive, and his study of Guyon's published cases confirms him in this opinion, as slight suppuration at first was frequent. The most important point is to leave the medium-sized soft, permanent sound until the healing process is entirely completed. He adds that dilation is unnecessary if the healing proceeds regularly as in his cases, but it should be resorted to at once at the first indication of a stricture or induration around the new-formed urethra. His cases have never required a sound since first dismissed.

PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance	\$5.00
Foreign Postage	1.75
Single Copies	10 Cents.

In requesting change of address, give *old* as well as new location.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, 100 Washington St., Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the *Editor*, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

SATURDAY, MAY 14, 1898.

THE HYGIENE OF CLOTHING.

It is probable that man was originally a tropical animal, perfectly adapted to his environment in a physical point of view. the natural product of evolution under the conditions in which he lived. Since he has emerged from his primal state and extended his habitat throughout nearly all latitudes and climates and has become a garment-wearing animal a host of unnatural and insanitary possibilities has arisen. The question of clothing, what to wear and how to wear it, has an importance altogether aside from the social and esthetic, and even from some of the ordinarily recognized considerations of comfort that commonly govern our selection. The hygienic choice of clothing, when it is not interfered with by conventional or economic or other factors, is usually a rule of thumb procedure, that takes little or no account of the chances or consequences of error. This is more especially true in our so-called temperate climates, where every extreme of temperature is experienced, often within the compass of a few days or weeks or in some localities even a day. The result is a sacrifice of human comfort, health and even of human life that is none the less formidable and real because it is unappreciated even by the victims themselves. The average layman's idea of hygiene is ordinarily that it is a matter that concerns diet, water-supply, drainage, etc., and the subject of clothing is one of the very last that occurs to him under this head. The relative importance attributed to these other matters by sanitarians encour-

ages this error, and it may be asked whether, as physicians, we are not guilty of forgetting or condoning some of the commoner sins against good health in this regard; our familiarity with them has led to their neglect. We change our summer and winter costumes, for example, according to the calendar or our individual whims and feelings, and the result is often a crop of lung and bronchial affections and the aggravation of those already existing. According to RUBNER, the most recent writer who has treated the subject systematically, the average man is, as a rule, too warmly clothed in summer, and this, even with good ventilation, is an evil that should be avoided, and tends to increased perspiration and abnormal activity of the skin, which in many ways may lead to evil consequences. With ill ventilated clothing confining the perspiration and its excretions, we have a condition that interprets itself, often to our unaided senses, as hardly more compatible in principle with perfect sanitation than is an undrained cellar sending its exhalations into the living rooms above. The necessary removal of clothing at least once a day relieves matters somewhat, but the betterment is only in degree, not in kind, and is at best only temporary if the same under-garments are resumed the following day. The problem of a proper and thoroughly healthful and comfortable summer costume in our climate adapted to all the exigencies of weather and occupation is certainly a complex one, and it is perhaps too much to expect that it can be perfectly solved. The best we can look for, perhaps, is to reduce the possible evils to a minimum, not to abolish them.

The question of winter clothing is, according to RUBNER, a simple one. the chief demand is for sufficient warmth; the excretory function of the skin is not so actively in evidence and the difference of external and bodily temperature in itself is sufficient to effect or materially aid in such ventilation as is required. The external conditions themselves more directly indicate the needs than is the case in summer, and errors are less likely to be made.

It is in the variable climates of our Northern States that the hygiene of clothing needs most particular attention, and more especially in the changeable weather of the transitions from winter to summer and summer to winter. In the tropics one readily learns how to adapt himself to his surroundings, and as a rule the white race in those regions does not attempt occupations that are unsuited to his conventional costume, at least, for any length of time. In the arctic regions also, the clothing is rationally adapted to the climate, and the freedom from colds and lung disease experienced there is not altogether due to the absence of germs. It is in the middle latitudes, in temperate regions, with their wide ranges of temperature and changing seasons, that the choice of clothing becomes a serious sanitary problem too often neglected,

but none the less important and worthy the earnest attention of the medical profession. The public is at present left too largely to its own devices as regards this matter, and while the result is not altogether as bad as it might be, it is certainly not an ideal one in a sanitary point of view.

JEALOUSY AS A DISEASE.

The *Lancet*, *British Medical Journal*, and other medical periodicals in Great Britain have lately been discussing the question whether jealousy can be regarded as a disease. Considering the number of physicians who have fallen victims to the morbid jealousy of inebriate husbands when suddenly called to a previously unknown parturient woman, the denial that jealousy can be at times morbid seems absurd.

As SPITZKA pointed out nearly two decades ago ("Insanity: Its Classification, Diagnosis and Treatment"): Delusions of alcoholism relate to the sexual organs, sexual relations and to poisoning. This fact is so constant a one that the combination of a delusion of mutilation of the sexual organs, with the delusions that the patient's food is poisoned and that his wife is unfaithful to him may be considered as nearly to demonstrate the existence of alcoholic insanity as any one group in mental pathology can prove anything. With this there are unpleasant hallucinations. There is this peculiarity of insane inebriates, that their acts are not consistently regulated by their delusions. Thus, one patient may live in comparative tranquility with a wife whom he suspects of committing adultery in the boldest way and before his face night after night. Another under the influence of the same delusions may, in mortal fear of being poisoned in her supposed paramour's interest, kill his wife in a fit of blind fury. These same delusions exist in women. KIERNAN has reported (*Journal of Nervous and Mental Disease*, 1886) two cases in which alcoholic insanity was correctly diagnosed from such symptoms in two American women who had never been suspected of the use of alcohol. Urticaria coincident with dysmenorrhea had led to the popular prescription of gin for this condition and its consequent abuse.

Although morbid jealousy may arise from neurasthenia, neuroses or psychoses taking the direction of the sexual organs especially in the degenerates, still, as just remarked, alcohol is particularly noticeable as a predisposing or exciting cause. Abuse of alcohol produces at first hyperesthesia and then resultant atony of the genital organs and diminishes the power of fecundation and sexual ardor. The genital pathologic lesions in inebriates resemble those of senility. The testicles atrophy, and the spermatozoa disappear. In the female menstrual irregularities occur, followed by amenorrhea. This degeneracy in sexual physiology

is, according to STEFANOWSKI (*Alienist and Neurologist*, 1893), accompanied by physical and moral impotence, of which jealousy is a necessary concomitant. According to KRAFFT-EBING, morbid jealousy often occurs among inebriates which may be a part of a general persecutorial state or may be a spontaneous phenomena at times. It is interlaced frequently like a red thread with the course of alcoholic psychic degeneration and appears often at the onset of alcoholic intoxication and leads the patients to bloody, sometimes mortal acts, against the innocent victims of their suspicions. KRAFFT-EBING has observed this morbid jealousy in 80 per cent. of inebriates still capable of sexual life. It can be explained as much by extreme enfeeblement of sexual power as by the erotic tendencies still existing. Such an inebriate feeling himself enfeebled in virility commences to have a suspicion, and to inquire, whether his wife have not become unfaithful. This suspicion becomes the point of departure of a morbid jealousy which has but too often fatal results.

Imperfect sexual anesthesia in the hysteric and sexual neurasthenic underlies the morbid jealousy so frequently shown by these. Prescription of marriage to sexual neurasthenics as a cure for their morbid state has sometimes dangerous results for this reason. Doubting their own sexual power, they are sceptical of being the parents of children born to them during the first year of marriage, and hence are victims of suspicions of marital infidelity on the part of their wives. In like cases during climacteric prostatic change, similar suspicions occur. In hysteric females, especially when masturbators, similar psychologic states are often present.

In dealing with the extent, influence, character and suffering from morbid jealousy, the fact should not be forgotten, that modern physiologic psychology denies any essential difference between mental and physical pain, both being species of the same genus. The experiments of OWSIANNIKOFF and DITTMAR prove that pain is accompanied by an arrest of nervous irradiation and spasm of the vasomotor nerves of the brain. MEYNERT interpreting these phenomena from a psychologic standpoint has constructed an ingenious explanation of morbid pain as produced by functional anemia of the cerebral cortex. FÉRE's researches tend in the same direction to the opinion that all unpleasant sensation can be resolved into a sensation of feebleness produced by cerebral anemia. F. PAULHAN made a happy attempt to explain all affective phenomena as results of an arrest of tendencies. The jealousy conception should hence be considered as a species of arrest of psychic irradiation. Love experienced for a person can be measured by the place this person occupies in mental life and the rôle, the words and acts of this person play in the organization of habits of thought. Thus are formed systems of ideas

and tendencies which become more and more organized. The unfaithfulness of a loved one is then a disorganization of the person loving, a destruction of the *ego*, an arrest of a great number of systems of ideas and tendencies. As this suffering is produced by real and in no respects delusional causes, it must be regarded as normal. It may however attain such intensity as to be shown in a pathologic manner. This is particularly true of the cases in which the jealous conception does not yield to the action of time but lasts for months and years without enfeeblement as do the delusional conceptions of the insane. In such cases it is impossible to regard the affected person as normal since the intensity and duration of the conception clearly demonstrates its pathologic nature.

The morbid element of jealousy is particularly noticeable and especially dangerous to physicians in cases of late jealousy. These, as STEFANOWSKI has shown, are far from rare in forensic practice.

A man marries a woman who had in her past some gallant adventure. This adventure had not been hidden from him. Knowing already the fault of his future wife, he had pardoned her with all his heart. His love for her was then so strong that to possess her solely he closed his eyes willingly on the past. The woman taught by one bitter lesson has become an honest faithful wife, devoted to her husband with whom she has lived several years without giving cause for suspicion. Nevertheless the husband little by little becomes jealous of the past of his spouse, the fire of his love is extinct and illusion is dissipated under the influence of habit, satiety or monotony of sensation. Jealousy is no longer counterbalanced by generous love, and he commences to hate the unfortunate woman, of whose past he has a conception in which there exists a rival who was happy before him. This rival he can not reach and all his vengeance is poured on the head of his wife, the sole victim of this tardy jealousy.

The dangers to medical men of morbid jealousy of the hyperesthetic type due to alcohol were well illustrated in the death of Dr. F. G. WILDER of Chicago at the hands of an alcoholic traumatic lunatic. The homicide (who had had a sunstroke and sustained a skull injury) was, in consequence, a suspicious lunatic with the periods of pseudo-lucidity common in that type. He became an inebriate and developed the alcoholic delusions described by SPITZKA and KRAFFT-EBING. In consequence he was sent to an insane hospital, whence he was released on parole during a pseudo-lucid interval. He was later liberated by a jury despite the remonstrance of physicians. Six months thereafter he called Dr. WILDER by a telephone message to an alleged patient, met him at the door and shot him dead. During the same year eight attempts at homicide of physicians were made by

inebriates laboring under morbid jealousy. In New York city one which was nearly successful was made by an inebriate husband on a passing physician, called to attend a woman, taken in labor on the sidewalk, who had been removed to the rooms of a family strangers alike to husband, wife and physician.

Morbid jealousy has not only its hyperesthesia as just described but also its anesthesia and its paresthesia. These alternating in the alcoholic type with the hyperesthesia constitute a treble danger. The sexual paresthesia of the hysteric is a fertile forensic source of danger to the character of the physician, but the morbid jealousy hyperesthesia is a source of danger to life as well.

CONCERNING ENDOCARDITIS, ITS PATHOLOGIC ANATOMY AND ETIOLOGY.

It might seem as though the study of acute endocarditis had been fairly well exhausted, if one were to judge by the large number of articles of various kinds that have appeared concerning this subject during the last few years. When one reads carefully, however, the recent monograph by FRANCIS HARBITZ,¹ of Kristiania, Norway, concerning endocarditis, its pathologic anatomy and its etiology, he may be agreeably surprised at finding that there are quite a few important clinical as well as etiologic and anatomic points in connection with this disease that have apparently escaped attention, and which could be brought out only by a careful histologic and bacteriologic study of a large series of cases.

HARBITZ passes in review the various phases of the history of endocarditis. He refers to the epoch-making work of BOUILLAUD, who was the first to establish the existence of endocarditis as a distinct clinical entity, and also the first to furnish the necessary anatomic basis. He then refers to the pioneer work of HEIBERG and WINGE, who, in 1869, were the first to establish the presence of microbes in the valvular excrescences and to demonstrate precisely their entrance through external lesions. He then shows that, after the discovery of the various specific micro-organisms, it was not long before many of them were assigned as the causes of infectious endocarditis.

In the description of the methods which he made use of in the study of his cases, HARBITZ lays particular stress upon the necessity of making histologic sections of the valvular vegetations and upon the study of cover-glass preparations in order to control the result of the bacteriologic examination and, finally, he refers to the necessity of comparing the pathologico-anatomic results with the history of the disease.

The classification he makes is founded upon etiologic principles and corresponds to that proposed by HANOT, and many other authors, who divide endo-

¹Om endokardit, dens pathologiske anatomi og ætiologi. Kristiania, 1897.

carditis into two principal classes, viz.: the infectious and the non-infectious, the latter comprising also those whose probable infectious nature has not been demonstrated.

In the first class are arranged the various inflammations of the endocardium that are due to the presence of streptococci, pneumococci, staphylococci and gonococci. The existence of endocarditis due to the bacillus of typhoid fever is regarded as proved, although it is very rare. On the other hand, he finds that there is hardly enough evidence at hand to warrant the establishment of a tuberculous endocarditis.

In the second class he places the endocarditis of rheumatism, as well as the numerous instances of endocardial vegetations which accompany tuberculosis, carcinoma, Bright's disease, etc.

HARBITZ studied, thoroughly, fifty-four cases. Of these, thirty-nine belonged to the first class, and of this number seventeen were due to streptococci, five to pneumococci, seven to staphylococci, and two to gonococci. Two others are attributed, one to an unknown micrococcus, the other to an unknown bacillus. And, finally, there are included here six cases of infectious endocarditis followed by healing after having passed through the various stages of evolution. Fifteen cases belonged to the second class: five occurred in connection with acute articular rheumatism, seven with tuberculosis, and three with other chronic diseases.

After having made a thorough bacteriologic and histologic study of the infectious forms of endocarditis, HARBITZ finds it convenient, as well from the pathologico-anatomic point of view as from the clinical and etiologic, to distinguish between two great groups of infectious endocarditis. One includes the endocardites which are frequently accompanied by considerable outgrowths, which cover a large surface and which are composed partly of a hyaline thromboid mass and partly of embryonal connective tissue. It is rare to find in these excrescences, round cell infiltration, and there are no necrotic zones surrounding the masses of bacteria. The bacteria are more frequently found toward the border of the thrombotic mass, which they often surround quite completely. In order to demonstrate this relation of the bacteria to the vegetations, it is necessary to make careful sections. The whole histologic and pathologic picture indicates the existence of a limitative process in these cases and not that of a destructive and ulcerative process. In the autopsies upon these cases there were found quite frequently numerous infarcts of the variety which is called pale or anemic and which are free from suppuration. There were no foci of suppuration in any of the other organs. Now, these forms of endocarditis are in the majority of cases caused by the streptococcus and pneumococcus, and these bacteria are present, as stated, most often in

huge masses. In general it is not possible to find any evidence as to the source of the bacterial invasion.

These forms of endocarditis present also certain striking peculiarities from a clinical point of view: their beginning is often insidious and their progress slow. There may be six months, and even one or two years, from the beginning of the disease while it comes under observation. Many of the cases appear to begin by cerebral embolism. In a certain number of the cases there was observed a slight fever of an indefinite type, and sometimes the joints would present symptoms that resembled very much the articular phenomena of acute rheumatism. Some of these cases also manifested marked renal symptoms, sometimes presenting the clinical picture of a hemorrhagic nephritis, due in part, perhaps, to mechanical disturbances in the circulation of the kidney on account of the valvular heart disease, although more likely to infectious or toxic agents.

As a supplement to this group HARBITZ describes certain cases of infectious endocarditis that heal spontaneously, in which there were large outgrowths upon the endocardium of the valves, as well as of the auricles and ventricles, but in which cultures remained sterile while the microscopic sections showed indistinct and degenerated bacterial masses at the borders of the vegetations. Judging by the appearances and by the resemblance of these cases to those already described, the author considers it very probable that these instances were cases of streptococcus infection. He believes that he has demonstrated the curability of infectious endocarditis. In these six cases there were also symptoms of infectious and toxic nephritis.

The second principal group of infectious endocarditis is formed by those cases in which the endocarditis represents part and parcel of a general pyemic process. These cases correspond to the clinical picture of malignant endocarditis. The lesions are most often ulcerative and destructive, and here one finds a necrotic zone around the bacterial masses, a marked round cell infiltration, and at the same time there will be found multiple suppurative foci here and there in the body, and also infarcts that are most often infected. These forms of endocarditis are most often caused by staphylococci. External lesions serve as the infection atrium and the evolution of the disease is rapid.

In two cases of infectious endocarditis the author found micro-organisms that morphologically and from the staining characteristics corresponded to the gonococcus. He was unable to cultivate them. After referring to the cases of gonorrheal endocarditis described in the literature, including that of THAYER and BLUMER,² HARBITZ concludes that it concerned here most likely the gonococcus.

² Archiv. de méd. expérimentale, 1895.

HARBITZ describes the endocarditis of rheumatism as characterized by small verrucose vegetations, which appear by preference to affect the endothelium over the free border of most of the valves and which remains strictly circumscribed in these localities. When such vegetations are examined while fresh they are found to consist of a hyaline thromboid substance, at the base of which there is a small mass of embryonic connective tissue. Bacteria are not found in cover-glasses, cultures, or sections. After reviewing the literature of acute articular rheumatism as far as it bears upon etiology, he comes to the conclusion that rheumatism can hardly be considered as a specific disease, but rather as resulting from the action of various pyogenic microbes of a feeble virulence. This is also the opinion of SAHLI and others. In support of this statement various cases are cited of fever and articular swelling connected with local suppurations. Now, as regards rheumatismal endocarditis, HARBITZ submits that this may be due to the same attenuated microbes, which act either directly by implantation upon the endocardium or indirectly by the excretion of toxic products which circulate in the blood. By the production of a superficial necrosis of the endothelium of the valves along the line of closure, which is the part most exposed to traumatism, there results a precipitation of thrombotic material from the blood, followed by a proliferation from the substance of the valve.

HARBITZ looks upon this pathogenesis as the one most likely also for the small verrucose excrescences which so often accompany tuberculosis, cancer, Bright's disease, etc., where the bacteriologic examination gives a negative result. In Bright's disease, for instance, it lies very near at hand to assume that the abnormal substances circulating in the blood may readily injure the endothelium. HARBITZ was not able to find tubercles or tubercle bacilli in the endocardial excrescences in cases of tuberculosis in various parts of the body. On the other hand, by inoculating one of the vegetations into a guinea-pig, he obtained, in one instance, positive results, but it may be that this was due to the implantation of tubercle bacilli circulating in the blood upon the vegetations.

Finally, it is to be noted that a number of animal experiments were made, in which he succeeded in producing an infectious endocarditis by the intravascular injection of different bacteria. On the other hand, injection of sterilized cultures did not produce any lesions of the valves.

THE BOYS OF NINETY-EIGHT.

In our issue of last week, in discussing the President's call for volunteers we deprecated the acceptance of minors for service. The country is populous and can easily furnish the required number of well developed and hardy men. Were the war prolonged as

was the civil war it might be needful to call the young men from their schools and colleges; but in the inception of a war this is not necessary and does not seem to be advisable. The boys are full of the war spirit and are anxious to be at the front; but the fatigues and exposures of active service would soon send them to the rear again, with, in many instances, the prospects of their lives destroyed. We cited approvingly the regulations for enlistment in the regular army which made twenty-one years the minimum age for acceptance into service; but while we were writing that approval an order was in preparation and has since been issued by the War Department making the minimum for enlistment in time of war eighteen years instead of twenty-one, as heretofore in times of peace. These requirements are alike opposed to the teachings of physiology and military experience. They should have been reversed. There is no objection to enlisting growing youths in times of peace as their years of service would be practically a course of athletic training and military discipline which would have a value in their future; but there are serious objections to calling them into the ranks in times of war while the country has able-bodied men available for service.

THE JOURNAL ON ITS TRAVELS.

A rather battered copy of the JOURNAL of March 20, 1897, arrived in the editorial room this week from Cape Town, Africa, having left that city April 4, 1898.

It was accompanied by the following letter from the accomplished editor of the *South African Medical Journal*:

CLAREMONT, CAPE TOWN, S. AFRICA, April 4, 1898.

The Editor JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, Chicago.

Dear Sir:—I forward to you by this mail your JOURNAL of March 20, 1897, which is quite a curiosity.

Until quite recently it was my custom to pick out from among my correspondents a few of those likely to be especially interested in any medical journal I might receive and to send the journal to them in rotation, one forwarding it on to the other.

To illustrate this the accompanying JOURNAL has drifted back to me after the following journey:

1. Dr. Welby, Colonial Surgeon, Island of St. Helena
2. Dr. Moffat, Chief Medical Officer, British East Africa, Warsinde Station, Varyoro, Uganda (the station is somewhere near Lake Victoria Nyanza).
3. Dr. Haw, Bartelsan, Transvaal.
4. Dr. MacFarlane, scribe Basulaland.
5. Dr. Robertson, Johannesburg, Transvaal.
6. Dr. Leicester, Port Elizabeth.
7. Dr. Howard, Port Nollarth, Namaqualand.
8. Dr. Eyre (myself).
9. Dr. Fuller, Cape Town.

This round has taken some little less than a year. If you will trace this route on the map and think that the article sent was only a book packet you will, I believe, realize that it is not uninteresting, an instance of postal perfection as well as a gratifying proof of the obligation of the professional bond felt by many personally totally unknown one to the other.

[Signed]

Yours faithfully,

GEORGE G. EYRE.

We feel gratified that through the courtesy of Dr.

EYRE, the representative American medical journal has thus passed through the hands and met the eye of our colleagues in darkest Africa, and we trust that the casual acquaintance with the writings of our American medical men thus begun may ripen into closer reciprocal relation. May the African pioneer medical men live long and prosper, and may the *South African Medical Journal* long flourish!

THE JOURNAL SPECIAL TRAIN TO DENVER.

The JOURNAL SPECIAL TRAIN will leave Chicago, Saturday, June 4, at 11 P.M., via the Chicago, Burlington & Quincy Railroad, arriving in Denver Monday morning 7 A.M., in time for the meeting of the American Academy of Medicine, the American Medical Editors' Association and other medical organizations holding sessions on Monday.

The "Special" will run through. Tickets will be good for thirty days. The rate will be one fare and \$2 for the round trip, the most favorable rate yet granted the ASSOCIATION.

CORRESPONDENCE.

Wyman's Method.

STATE BOARD OF HEALTH OF KENTUCKY, /
EXECUTIVE OFFICE. \

BOWLING GREEN, KY., May 2, 1898.

To the Editor:—In the April 1 number of "Health Reports," published by the United States Marine-Hospital Service, the statement was officially made that, during the recent epidemic of smallpox at Middlesboro, national aid was sent to this State at the request of this Board and of Governor Bradley, and that the representative of that Service found the methods of this Board inefficient. As the epidemic was practically under control at the time of the unwarranted interference of this Service, and as their interference was wholly uninvited, I at once wrote the Supervising Surgeon-General asking that the false and unjust statements be corrected. As he has declined to make this correction, and as this Bureau is the chief obstacle to the enactment of efficient national legislation for the protection of the public health interests of the country, I ask that the subjoined correspondence be given a place in your columns, that health officials and the profession may know what to expect at the hands of this Bureau should its persistent requests for increased power be granted. Very respectfully,

J. N. McCORMACK, Secretary.

EXECUTIVE OFFICE,
BOWLING GREEN, KY., April 9, 1898.

DR. WALTERS WYMAN, Supervising Surgeon-General United States Marine-Hospital Service, Washington, D. C.

Dear Doctor:—I write to correct a mis statement made in the current number of your Public Health Reports to the effect that this Board, the Governor of Kentucky or anyone else having authority to do so, asked for national aid in suppressing smallpox at Middlesboro. The request was made by Representative Colson, who had no authority in the matter whatever, as you must have known. When your representative arrived the disease was under control, and a speedy termination of the epidemic was confidently expected, as he reported to you when he asked to be relieved. You ordered him to stay but, under his instructions, he refused to co-operate with us or do anything unless given absolute control, and by reckless statements made to certain citizens as to government funds

available if he got this control, so confused our efforts to get money from the county, which was amply able to raise it, that our Board withdrew and the State was forced to accept a co-operation from your Service it had never sanctioned or needed. We hesitated to give you absolute control because of the ineffectual methods adopted by your Service in Alabama which had permitted the present epidemic in Tennessee and Kentucky, and of its similar history in former years in dealing with yellow fever and smallpox. After our inspectors left, your representative found that he had no authority to assume charge. Our quarantine was continued in force to protect the rest of the State but no one had charge in Middlesboro for almost a week, and the disease made such headway that it has required over a month to bring it under control to the same degree as when we left. With all due respect to you and your Service we are satisfied that your interference was unauthorized and unwise, and ask that this correction be given place in your next issue. With assurances of personal regard,

Very respectfully, J. N. McCORMACK, Secretary.

TREASURY DEPARTMENT,
OFFICE OF THE SUPERVISING SURGEON-GENERAL
MARINE-HOSPITAL SERVICE.

WASHINGTON, D. C., April 13, 1898.

DR. J. N. McCORMACK, Secretary State Board of Health:

Dear Doctor:—In reply to your letter of April 9, 1898, in which you request a correction of alleged mis-statements made in the current number of the Public Health Reports regarding smallpox epidemic in Middlesboro, I have to say that the statements in said Public Health Reports are verified by the records of this office, which show that not only the Governor of Kentucky and a member of Congress for the District including Middlesboro, and the president and secretary of the State Board of Health of Kentucky, requesting national aid in suppressing the epidemic of smallpox at Middlesboro, but that a similar request was also made from the Mayor of Middlesboro; so that your request for a correction was evidently made under a misapprehension of the facts.

Contrary to your assertion, no instructions were given to Dr. Wertenbaker to refuse to co-operate or do anything unless given absolute control.

You are equally in error in regard to the success of the Service in the methods adopted for the suppression of the epidemic in Alabama, as the Service never assumed charge of smallpox throughout the State of Alabama, its operations being in Birmingham and vicinity.

With regard to the history of this Service in dealing with yellow fever and smallpox in former years, it is only necessary to call your attention to the Annual Reports of the Service, as well as the Public Health Reports, to prove the incorrectness of your statement.

Respectfully yours,
[Signed] WALTER WYMAN,
Supervising Surgeon-General, U. S.

EXECUTIVE OFFICE,
BOWLING GREEN, KY., April 20, 1898.

DR. WALTER WYMAN, Surgeon-General U. S. Marine-Hospital Service, Washington, D. C.:

Dear Sir:—I regret very much that you feel it necessary to make the statements contained in your letter. Your records can not show that the officers of this Board or the Governor of Kentucky asked you to send any one to Middlesboro for the very simple reason that they did not do so. After Dr. Wertenbaker was sent without official invitation, he reported to you that we had the epidemic under control, that no inter-State question was involved, and asked to be relieved. You ordered him to remain for reasons best known to yourself, until his presence, and your promise to furnish funds, demoralized the local officials, who had from the first objected to bearing the expense properly imposed under our statutes. Under a gross

misrepresentation of the facts the president of this Board and the Governor were induced to ask your Service for aid, and I withdrew our inspectors when it was found that Dr. Wertenbaker had no authority to do anything. Chaos reigned for several days, hundreds were exposed and the epidemic was again on, and was only prevented from reaching serious proportions by the systematic vaccination done by us before your interference. I have no means of knowing what instructions you gave Dr. Wertenbaker, but he stated in a public meeting, and often in private, that he could only co-operate with us upon condition that he was given absolute control.

As you refuse to make the correction demanded alike by the facts and fair dealing, I will be forced to take my own methods of doing so.

Respectfully,

J. N. McCORMACK, Secretary.

Appendicitis.

NEW YORK CITY, May 8, 1898.

To the Editor:—There have been no responses in the JOURNAL in answer to my request in a February number, asking correspondents to oppose the idea that appendicitis cases require operation as soon as the diagnosis has been made. Several references to my request have been made in other medical publications, however, and one which appeared as an editorial in the March number of the *Texas Medical News* covers the ground of the oppositionists so well that I have asked the editor of the *News* to allow me to answer in the JOURNAL, because that was the medium which I chose originally for the discussion. (I have italicized the parts of the republished *News* editorial which are answered *seriatim*.)

EDITORIAL ARTICLE.

"There are always to be found men occupying *extreme positions* in every profession. This is especially so in medicine and surgery. Men, too, of learning and influence, teachers and authors, whose teachings and example are quoted and followed by men of less positive character. We feel that we are guilty of no exaggeration when we assert that such men have been in the past, and are yet, dangerous elements in the medical profession. They are a menace to the well-being of society. We are forcibly reminded of this fact by a letter from Dr. Robert T. Morris, in the February issue of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, on the subject of operation in appendicitis. The clear inference which may be drawn from the letter is that operation should be resorted to without delay as soon as the diagnosis is made.

"We repeat that such extreme radical teaching by influential members of the profession, such as Dr. Morris, is well calculated to do great injury, by *precipitating an epidemic of laparotomies* by a large class of surgeons who always follow their leaders, and always consider themselves safe from adverse criticism as long as they are fortified by 'authorities.' Similar teachings a few years ago, precipitated upon the unfortunate women of this country an epidemic of operative procedure for the relief of *ovarian disease*, and there is not a doubt but that thousands of healthy ovaries were thereby sacrificed to the sinister teaching of a few leading members of the profession. We are glad to know that conservative surgery has at length placed a check upon this needless sacrifice of the procreative faculties of women, and the great pendulum of public opinion is moving in the opposite direction. And so it will prove, we trust, in operations for appendicitis. *Conservatism* will assert its influence and power, and *nature will first be given a chance*, assisted by the intelligent efforts of the physician, to remove *trifling ailments* in and about the appendix, before the peritoneal cavity is invaded by the surgeon's knife. We know from our own experience and observation that *a great majority of such cases recover without operation*, and we earnestly exhort the members of the profession to use *their own judgment* in every case of appendicitis as to the propriety of operation. We notice in the communication of Dr. Morris, above alluded to, an apparent *intolerance of the opinion, and even of the truthfulness*, of other members of the profession, which we think sadly out of place in the discussion of a subject involving as it does the lives and welfare of the people. Infallibility must not be credited to any one, and experience from every source upon this important subject is valuable to the profession, and should

not be captiously objected to or rejected because it does not accord with our own opinions or experience."

ANSWERS.

1. *Extreme positions*.—It makes a difference whether an extreme position is based upon knowledge or upon theory. The subject of appendicitis is so thoroughly understood by a part of the profession, and the data are so well classified, that we can now maintain the extreme position that operation should be done as soon as the diagnosis of appendicitis has been made. In diphtheria we take the extreme position that every case of true diphtheria should be isolated, because of the danger of its infecting other patients. In appendicitis we take the extreme position that the infected appendix should be isolated because of the danger of its infecting other structures. It is not a question of theory so much as a question of fact.

2. *Precipitating an epidemic of laparotomies*.—This is a matter for which society is responsible. The teaching is not at fault. If society allows badly educated men to graduate from medical colleges, and poorly equipped men to operate for appendicitis, to society must come the consequences.

The teaching of a correct surgical principle should not be abrogated on the ground that many improperly prepared men will try to carry it into effect. Judges know how many legal cases are lost for clients, because lawyers prepare the cases improperly for trial, but the judges do not argue that principles in law should not be taught to all classes of lawyers.

3. *The epidemic of operation for diseased ovaries*.—That again was a case in which correct principles were taught, and unprepared men often tried to carry them into effect. The careful, conscientious, educated gynecologist is a trustworthy man, and in him the good people may repose confidence. The responsibility for pendulum movements lies chiefly with the sort of people who do not choose the careful, conscientious, educated gynecologist or surgeon when wise counsel is needed.

4. *Conservatism in treatment of appendicitis*.—I would call the attention of philologists to the curious use that is made of the word "conservatism" as applied in appendicitis controversies. "Conservative treatment" is understood to mean medical treatment during a part or the whole of an acute attack of bacterial infection of the appendix. The death rate in appendix treated by medical means alone has been shown to amount to more than 10 per cent. in primary attacks, and more than 25 per cent. eventually. The death rate in appendicitis under proper surgical treatment at the proper time has been shown to be less than 1 per cent. at the hands of several American surgeons, but this is curiously enough known as "radical treatment" in contradistinction to "conservative treatment" with its high death rate. The suffering caused by bacteria during "conservative treatment" is much greater than the suffering caused by "radical treatment," if we may judge from the testimony given by a series of patients whose answers to questions are to appear in a forthcoming number of the *Medical Record*. The loss of time to the patients is greater under "conservative treatment" than under proper "radical treatment." We hear a good deal about treating cases "conservatively until operation is required." This phrase usually means that the cases are to be allowed to drift into such complications that the patient may be expected to suffer from the results of complications after the operation has been done.

Philologists then will please take note on the curious use of the word conservatism as it has come to be applied in appendicitis controversies. If the philologists wish to know the reason for this use of the word, I will remind them that conservatism takes the place of knowledge, that a large part of the profession is uninformed upon the subject of appendicitis, that the word "operation" has more disagreeable suggestions than the word "bacteria" unless one is fully informed upon both subjects, and that the very busy physician is in such demand by his patients that it is a physical impossibility for him to man-

age the unwieldy sum-total of our advanced medical knowledge of today. The outlook is more and more hopeless unless we can some day have a medical tribunal or clearing house, for classifying that part of our knowledge that has become scientific, and obstructing the publication of crude controversial articles which confuse the busy physician who is eager to be upon the right side.

5. *Giving nature a chance.*—A chance to do what? To raise a thriving colony of bacteria or to destroy them with polynuclear leucocytes in the interests of the man? Nature presumably cares no more for a man than she does for a fine nest of growing bacteria. Both are her possessions. She wishes to have both of them survive. She has equipped both of them with means for offense and defense. When there is a struggle for supremacy and nature does not seem to know which side to favor, the well informed patient chooses a skilful surgeon for his ally, and nature is not given a chance to cultivate her bacteria at the expense of a beloved father, or mother, or sister, or brother. It is a pretty conceit on the part of man, this assumption that nature cares more for his welfare than for the welfare of a progressive thriving colony of bacteria. It is parallel to the idea that man must be a special creation.

6. *Trifling ailments about the appendix.*—None of my remarks apply to the matter of trifling ailments about the appendix. They apply only to cases of true infective appendicitis in which bacteria are injuring the tissues, and in which the physician possesses sufficient diagnostic acumen to know what is going on.

7. *Majority recover without operation.*—About 75 per cent. of appendicitis patients are believed to recover without operation (See "Lectures on Appendicitis," Second Edition), but at what cost? At the cost of risking a death-rate of 25 per cent. which need not be 1 per cent. At the cost of more suffering, and more loss of time, and more chronic ill health than any one within reach of the resources of modern civilization need suffer.

8. *Members of profession to use their own judgment about propriety of operation.*—Within a month I have seen two cases in which the free abdominal cavity was filled with pus, and in which some of the consulting physicians thought that symptoms did not warrant operation. Within a year I have seen at least six cases in which the appendix was the focus of tuberculous infection which was extending to peritoneum and neighboring bowel, and yet the symptoms were so mild that several consultants had advised against operation. I have seen a case of cancer of the appendix in which consultants were not at all agreed that the symptoms were sufficient to warrant operation, until the cancer had reached an incurable stage. Within a year I have operated upon perhaps twenty-five cases in which perforation of the appendix had already occurred, and in which some of the consultants thought that the symptoms were those of "catarrhal appendicitis" only. Shall we then let members of the profession all use their own judgment, or shall we ask the men who are thoroughly familiar with the subject to teach principles and make rules for aiding those whose opportunities for gaining accurate information have been more limited. Human life is directly at stake in this matter. Physicians are directly responsible, because trusting patients place their lives, their hopes, their all, in the hands of physicians who are not at all prepared to take such sacred responsibilities.

9. *Intolerance of opinion of others.*—I am tolerant of the opinion of every man who tries to obtain his facts in a scientific manner. I am intolerant of the opinion of any man who becomes intoxicated by the spirit of controversy, and who tries, when, in that condition, to mislead himself and every one else. I have not questioned the truthfulness of any physician who has published lists of appendicitis cases cured by medical treatment, but have simply charged such authors with being slovenly and careless while they were intoxicated with the spirit of controversy. I have been, and shall be, upon the watch for all such published lists, and shall expect to find in

the future, as I have in the past, that a very little cross-questioning is disastrous to the authors of lists of "cured cases." They will be requested to give us the time during which appendicitis patients have been watched, the number of recurrent attacks, the number of deaths, the number of patients who subjected themselves to operation, and the length, breadth, position and condition of the appendices as determined by palpation in the interval between attacks. Patients will not be considered to be cured because they did not return for treatment.

The particular author whom the editor of the *News* suspects has been charged with untruthfulness, published a long list of cases of appendicitis cured by medical means, and when I challenged the accuracy of his report he admitted that he did not know what had become of most of the cases. I learned shortly of three of his cases that had subjected themselves to operation, of one that was carrying a chronic pelvic abscess from appendicitis. Another one of the patients came to my office because the symptoms had recurred, and the case proved to be one of loose kidney, with the kidney in the appendix region. The appendix was normal.

I did not charge this author with being untruthful, but simply intimated that he was intoxicated with the spirit of controversy, and when in that condition he was slovenly in making up his report. Hundreds of physicians and laymen are misled by such reports. The farce tragedy has been played long enough. Human life is directly at stake, and I propose to call to account physicians who insist upon trying to mislead themselves and others. Call it intolerance if you will, but I have no motive excepting that of being useful to the profession to which I have sworn allegiance, and there will be no intolerance manifested toward the author of any paper which takes into account our classified knowledge on the subject of appendicitis, and which bears the ear marks of that degree of care which is required in reporting upon a subject which directly involves human life.

49 West Thirty-ninth St.

ROBERT T. MORRIS, M.D.

Air is Food; Nitrogen: Correction.

NEW YORK CITY.

To the Editor:—In your issue of Feb. 12, 1898, there were omissions in "Air is Food; Nitrogen": page 365, column 1, lines 46 to 52; page 366, column 1, lines 1 to 5, 6 to 9, 16 to 20, 25 to 29, 34 to 39. These were quotations from the late Dr. W. Thornton of Boston. My explanation is that said quotations were in Prof. W. B. McVey's contribution and that I did not know they were Dr. Thornton's. Professor McVey says that he thought he had given credit. As he is now investigating N. on these lines, it is to be hoped that Dr. E. C. Hebbard of Boston (who kindly brought the matter to my attention and whom I thank), and all who feel that N. is not given its due dynamic influence, will work together, especially now when the whole world has been startled by the blowing up of the *Maine*, which would have been impossible without nitrogen.

Yours truly,

EPHRAIM CUTTER, M.D.

Location of Intestinal Obstruction.

LA GRANGE, ILL., May 7, 1898.

To the Editor:—Supplementary to the suggestion of a "Simple and Safe Method in Determining the Location of Intestinal Obstruction," by R. S. Reed of Wheeling, W. Va., I call the attention of the writer to the curious fact, pointed out by Nothnagel of Germany, that when a crystal of carbonate of soda is applied to the peritoneal surface of the intestines, it will invariably excite its contraction and which passes upward toward the stomach, antiperistaltic; never toward the rectum. But one opportunity to test this has been afforded me, which, however, corroborated the assertion of Dr. Nothnagel.

F. A. SCHMIDT, M.D.

ASSOCIATION NEWS.

The Denver Meeting.

Announcement.—The following arrangements have been made for the Denver meeting of the AMERICAN MEDICAL ASSOCIATION:

Section Dinners will be given June 7, at 7:30 P.M., and social entertainments will be given on other evenings during the week. Ladies' headquarters will be at Unity Church, where they will be received by the wives of physicians of Denver. Arrangements have been effected for their entertainment during their visit, and committees will escort the visiting ladies to the various points of interest in Denver.

On Friday June 10, a complimentary excursion to Idaho Springs and around the loop will be given by the Colorado State Medical Society. At Idaho Springs, the ASSOCIATION will be entertained by the citizens.

On Saturday, a complimentary trip will be made to Colorado Springs under the auspices of the Committee of Arrangements. At Colorado Springs the ASSOCIATION will be entertained by the local physicians and citizens. Visits will be made to all points of interest in the vicinity. Arrangements will be made for trips to Pike's Peak and the celebrated mining camp of Cripple Creek at low rates of fare.

At a date to be determined, special trains for Glenwood Springs will leave Colorado Springs via The Denver and Rio Grande Railroad and the Colorado Midland Railroad. Tickets \$5.00, good going via one railroad and returning the other, and for ten days from date of issue.

The trip to Glenwood is one of the most attractive in Colorado, giving excursionists a view of some of the finest scenery in the Rocky Mountains, including Pike's Peak, Ute Pass, the Valley of the Arkansas, Hagerman Pass, Canons of the Roaring Fork and Frying Pan, Canons of the Grand and Eagle Rivers, Tennessee Pass and the Royal Gorge of the Arkansas and passing through the cities of Pueblo, Leadville, Canon City and Florence.

Special Hotel rates will be given by the Hotel Colorado and other Hotels of Glenwood Springs. The springs, baths and swimming pool will be free to the ASSOCIATION.

Special cars will be hauled on the Colorado Springs train and the Glenwood Springs Special, only when handed to the railroads with their full capacity.

Railroad Rates.—As previously announced, the Western Passenger Association (including all lines running between Chicago and Denver) has granted a rate to Denver and return of one-half fare, plus \$2, thirty day limit, for business from Chicago, St. Louis and intermediate points. Tickets on sale June 2, 4 and 5 east of the Missouri River; June 5 and 6 west of the Missouri River.

The same rate is announced by the Frisco Line, the Missouri, Kansas and Texas Railway and the Fort Worth and Denver City Railway.

The Central Passenger Association have agreed to adopt the rate of the Western Passenger Association throughout the territory covered by their lines, and formal announcement is expected shortly.

From Ogden and Salt Lake, the round trip rate of \$20, thirty-day limit, will be in force.

The rate of one fare for the round trip from the common points, Pueblo, Colorado Springs and Denver, to points in Colorado is also announced.

Excursion tickets to Salt Lake and Ogden will be on sale at Denver on the closing date of the meeting and on the two days following, good to return twenty days from date of sale. Stopovers will be allowed within a transit limit of ten days. Rate \$18.

Rates over other lines will be announced as soon as determined.

COMMITTEE OF ARRANGEMENTS.

Section Dinners.—The following Section Dinners will be given at the Denver meeting of the AMERICAN MEDICAL ASSOCIATION on Tuesday, June 7, at 7:30 P.M.:

Practice of Medicine, Metropole Hotel.
Surgery and Anatomy; Obstetrics and Diseases of Women; Ophthalmology, Brown Palace Hotel.
Laryngology, L'Imperiale Hotel.
Materia Medica, Pharmacy and Therapeutics; Cutaneous Medicine and Surgery, Windsor Hotel.
Diseases of Children, The Albany Hotel.
Neurology and Medical Jurisprudence, University Club.
Stomatology, St. James Hotel.

In order that satisfactory arrangements may be made for dinners, it is essential that all members who expect to be present notify the Chairman of Committees on Section Dinners as soon as possible and not later than June 4.

E. C. RIVERS, Chairman,
16th and Stout Sts., Denver, Colo.

Railroad Rates for the Denver Meeting.—The Committee on Transportation, appointed at the Philadelphia meeting, consisting of Drs. H. L. E. Johnson of Washington, D. C., Charles A. L. Reed of Cincinnati and Henry D. Holton of Vermont, have been very active in their endeavors to secure a one fare rate with diverse return route and thirty days limit, to the members of the ASSOCIATION. The western roads have been late in promulgating their action to the other Railroad Associations, and the Central Traffic and Trunk Lines Association will not act until Tuesday, the 11th, instant, after which the Transportation Committee, which has co-operated with the Denver Committee of Arrangements, will make their report through the JOURNAL. The Pennsylvania road is in full sympathy with the rate movement of the physicians and it is working in the Trunk Lines Association to secure the rate desired. In securing reduced rates in the East, the Committee has had to face the fact that the ordinary rate per mile is less than the mile rate in the other passenger territory, hence the one and a third rate granted in the East is practically the half fare rate of the West. The Committee expects, however, to be able to report the one fare rate, for the Denver Meeting.

H. L. E. JOHNSON, Chairman Transportation Com.

Hotels.—The following is a list of the principal hotels of Denver with the rates agreed upon for the meeting:

The Brown Palace Hotel, 17th Street and Broadway. Take 17th Street (red) car to Hotel. European plan, \$1.50 per day and upward.

The Windsor Hotel, 18th and Larimer Streets. Take 17th Street car to Larimer Street. American plan, \$2.00 per day; room with bath, \$2.50 per day.

The Albany, 17th and Stout Streets. Take 17th Street (red) car to Hotel. American plan, \$2.00 to \$3.50 per day.

The Markham Hotel, 17th and Lawrence Streets. Take 17th Street car to Hotel. European plan, \$1.00 per day and upward.

All reservations at the Albany and Markham must be for the full term of the Meeting, and be paid for whether occupied or not unless canceled ten days in advance. They reserve the right to place persons occupying a room alone in a single room.

The New St. James Hotel, Curtis near 16th Street. Take 17th Street (blue) car to Hotel. American plan, \$2.00 to \$3.50 per day.

L'Imperiale, 14th Street and Court Place. Take Colfax Avenue car to Court Place. American plan, \$2.00 to \$3.00 per day.

Metropole Hotel, Broadway near 17th Street. Take 17th Street (red) car to Broadway. European plan, \$1.00 to \$2.00 per day. \$1.00 rooms, \$1.50 if occupied by two persons. No reservations made.

The Oxford Hotel, 17th and Wazee Streets. Two blocks above depot. European plan, \$1.00 to \$3.00 per day. An extra charge for two persons in one room.

The American House, 16th and Blake Streets. Take 16th Street car to Blake Street. American plan, \$2.00 per day.

The above hotels make no extra charge for reservations or for persons occupying a room alone except as stated.

The Hotel Broadway, Cheyenne Street and Broadway. Take Colfax Avenue car to Cheyenne Street. American plan, \$1.25 to \$1.50 per day.

The Vallejo, 1420 Logan Avenue. Take Colfax Avenue car to Logan Avenue. American plan, \$2.00 per day and upward.
The Devonshire, 14th and Logan Avenues. Take Colfax Avenue car to Logan Avenue. American plan, \$1.50 per day and upward.

The Albert, 17th and Welton Streets. Take 17th Street (red) car to hotel. European plan, \$1.00 to \$1.50 per day.

The Aldine, 1013 Seventeenth Avenue. Take 17th Street (red) car to hotel. American plan, \$1.25 per day.

The Richelieu, 1727 Tremont Street. Take 17th Street (red) car to Tremont Street. European plan, \$0.50 to \$1.00 per day.

The Earl, 1430 Tremont Street. Take Colfax Avenue car to Tremont Street. American plan, \$1.50 to \$2.00 per day.

Glenarm Hotel, Glenarm and 15th Streets. Take Colfax Avenue car to hotel. European plan, \$1.00 per day and upward.

The Bonaventure, 18th and Glenarm Streets. Take 17th Street (red) car to Glenarm Street. European plan, \$0.50 to \$1.50 per day.

The Drexel, 17th and Glenarm Streets. Take 17th Street (red) car to hotel. European plan, .75 to \$1.50 per day.

These hotels make small extra charges for two persons occupying same room. No charge for reservation.

Applications for rooms should be made to the hotels direct. For special information apply to ROBERT LEVY, M.D., Chairman Sub-Committee on Hotels, California Building, Denver, Colo. J. W. GRAHAM, M.D., Chairman.

W. A. JAYNE, M.D., Secretary.

Rush Monument Fund.—The following subscriptions to the Rush Monument Fund have been received:

June 10, 1897, Dr. Elmer Lee, New York	\$ 1.00
June 10, 1897, Dr. E. D. Ferguson, Troy, N. Y.	5.00
June 10, 1897, Camden Co., N. J., Medical Society (through Dr. J. M. Ridge)	21.00
Dec. 14, 1897, Dr. H. D. Holton, Brattleboro', Vt.	100.00
Through Committee of American Medico-Psychological Association, from Dr. G. Alder Blumer, Utica, N. Y.	5.00
Dr. D. R. Burrell, Canandaigua, N. Y.	5.00
Dr. Gershom H. Hill, Independence, Iowa.	10.00
Dr. F. C. Hoyt, Clarinda, Iowa	5.00
Dr. C. S. Applegate, Clarinda, Iowa	2.00
Dr. Anna Burnett, Clarinda, Iowa	2.00
D. A. T. Gundry, Clarinda, Iowa	1.00
Dr. H. A. Gilman, Mt. Pleasant, Iowa	5.00

Total \$ 162.00
 Before reported (June, 1897) 4112.44

Total \$4274.44

GEORGE H. ROHÉ, Secretary and Treasurer.

Section on Practice of Medicine.—The following papers are announced:

Address of the Chairman, by Samuel A. Fisk, Denver.

Discussion on Perforative Peritonitis, by J. C. Wilson, Philadelphia; J. B. Deaver, Philadelphia; F. C. Shattuck, Boston; Nicholas Senn, Chicago; W. S. Halsted, Baltimore; W. W. Keen, Philadelphia; J. H. Musser, Philadelphia; W. M. Polk, New York; C. G. Stockton, Buffalo; A. Lawrence Mason, Boston.

Yellow Fever, by P. E. Archinard, New Orleans.

Differential Diagnosis Between Yellow Fever and Dengue, with Some Account of the Epidemic in Texas of 1897, by H. A. West, Galveston.

(a) Diagnosis and Treatment of Headaches Due to Intestinal Toxemia; (b) A Case of Pernicious Anemia Due to Intestinal Toxemia, by Judson Daland, Philadelphia.

Weil's Disease, by N. S. Davis, Jr., Chicago.

Course and Management of Chronic Complicating Myocarditis, by Louis Faugeres Bishop, New York.

What Caused the Great Mortality Among the Plymouth Pilgrims in 1620? by I. N. Danforth, Chicago.

Physiologic and Clinical Relations of the Papillary Muscles of the Heart, by Henry Sewall, Denver.

Differentiation of Cardiac Incompetency of Intrinsic Heart Disease and Chronic Nephritis, by Frank Billings, Chicago.

Treatment of Diseases of the Duodenum by Direct Methods, by Fenton B. Turck, Chicago.

Dilatation of the Stomach, with Reports of Cases Treated by Diet, Massage and Intra-gastric Electricity, by Boardman Reed, Philadelphia.

(a) Nephritis Without Albuminuria; (b) Acute Febrile Jaundice, Arthur R. Edwards, Chicago.

Diabetes Mellitus at the Massachusetts General Hospital, from 1821-97; A Study of the Records, by Reginald H. Fitz and Elliott P. Joslin, Boston.

Subject to be announced, by James Tyson, Philadelphia.

Rare Forms of Arrhythmia, by J. M. Anders, Philadelphia.

A Consideration of Four Cases of Epilepsy, with a Reference to the Cause, by Charles S. Bond, Richmond, Ind.

Rheumatoid Arthritis in a Child; Illustrated with Skiagraphs, by J. B. Marviu, Louisville.

The Association of Chronic Diarrhea with Achylia Gastrica, by Allen A. Jones, Buffalo.

Stomach Disturbances Caused by Hernia Epigastrica, with Report of Cases, by Charles D. Aaron, Detroit.

The Value of Sweat on Excretion, with Some Experiments, by Lewis R. Morris, New York.

Indol, Indican and Indigo Blue; Their Pathologic Significance and Clinical Value, by F. Leonard Vaux, Toronto.

Results from Some Experiments on Rabbits Imported to Colorado from the Sea Level, Conducted to Ascertain any Difference in the Bactericidal Action of Their Blood and the Accompanying Blood Changes, by Louis E. Livingood, Baltimore, and Gerald E. Webb, Colorado Springs.

The Influence of Sunlight on Tubercular Sputum in Denver, by W. C. Mitchell and H. C. Crouch, Denver.

The Treatment of Pulmonary Sepsis, by James T. Whittaker, Cincinnati.

The Treatment of Tuberculosis with the Products of Tubercle Bacilli, by Prof. Edwin Klebs, Chicago.

Some Neglected Physical Signs in Chest Diseases, by Norman Bridge, Los Angeles.

Additional Experiments with my Anti-phthisis Serum T. R., by C. Fisch, St. Louis.

Oxytuberculin in Tuberculosis, by J. O. Hirschfelder, San Francisco.

(a) The Diagnosis of Pulmonary Tuberculosis when the Tubercle Bacilli are not Present in the Sputum; (b) The Treatment of Pulmonary Tuberculosis, by DeLancey Rochester, Buffalo.

The Influence of the Climate of Arizona on Cases of Chronic Tuberculosis, by E. Everts, U. S. A., Whipple Barracks, Arizona.

Tuberculosis in Combination with Syphilis, by Carl Reudi, Arosa, Switzerland.

Tuberculosis and its Treatment by the Later Methods; Subject Illustrated by Twelve Clinical Cases, by A. G. Deardorff, San Francisco.

Modern Methods of Dealing with Pulmonary Consumption, by William F. Waugh, Chicago.

Permanent Cure of Tuberculosis by the Use of Anti-tubercular Serum (Paquin), by J. A. Dunwoody, Cripple Creek.

The Medical Treatment of Appendicitis, by Elmer Lee, New York. Discussed by E. J. A. Rogers, Henry Sewall, E. J. Rothwell, E. P. Hershey, B. C. Leavitt, C. E. Edson, Denver.

The Cataphoric Treatment of Cancer; a further Contribution, by G. Betton Massey, Philadelphia.

The Psychology of Habitual Constipation, by A. H. Burr, Chicago.

Rest; a Neglected Factor in the Therapeutics of Gastro-enteric Diseases, by C. D. Spirak, Denver.

Report of Case: Aneurysm of the Concavity of the Transverse Arch, Appearing Externally as a Large Tumor in the Region of the Heart; Exhibition of Specimens, by H. W. McLaughlin and William N. Beggs, Denver.

The Causes of the Inconstancy of Mitral Systolic Murmurs, by J. N. Hall, Denver.

Three Cases of Toxic Hemoglobinuria: Two Deaths, One Recovery, by George J. Hirth, Milwaukee.

Section on Obstetrics and Diseases of Women.—The following additional papers are announced for this Section:

Septicemia of Nasal Origin Complicating Celiotomy, Hugo O. Pantzer, Indianapolis, Ind.

Uterus and Child from the First Week of Gestation to the Commencement of Labor and the Formation of the Placenta, E. Gustav Zinke, Cincinnati, Ohio.

Treatment of Pelvic Abscesses, Howard A. Kelly, Baltimore.

Suspensio Uteri and Alexander's Operation; Which? When? How? D. C. Brockman, Ottumwa, Iowa.

The Rational Treatment of Chronic Endometritis and Metritis, Augustin H. Goelet, New York City.

Surgery of the Common Bile Duct, W. E. B. Davis, Birmingham, Ala.

The Use of the Curette in Acute Infection of Uterus with Adherent Placenta, D. S. Fairchild, Clinton, Iowa.

Gonorrhea as a Factor in Puerperal Fever, Albert H. Burr, Chicago, Ill.

A Valuable Modification of the Apostoli Treatment of Fibroid Tumors, G. Betton Massey, Philadelphia, Pa.

Sigmoid Surgery from the Intra-Pelvic or Intra-Abdominal Standpoint, J. G. Carpenter, Stanford, Ky.

A Plea for the More Correct Application of the Emmet Method in Plastic Surgery, W. D. Haggard, Jr., Nashville, Tenn.

Section on Stomatology.—Dr. G. V. I. Brown, Milwaukee, Wis., Chairman; Dr. Eugene S. Talbot, Chicago Ill., Secretary. The following papers will be presented at the next meeting:

Chairman's Address, by G. V. I. Brown, Milwaukee, Wis.
Methods of Teaching Materia Medica, with Special Reference to the Needs of Dental Students, by W. B. Hill, Milwaukee, Wis.

A Method of Handling Alveolar Pyorrhea, by G. T. Carpenter, Chicago, Ill.

Only a Baby Tooth, by W. H. Hall, Denver, Colo.

The Management of Pulpless Teeth, by J. Taft, Cincinnati, Ohio.

Eplulides, by W. Knight, Cincinnati, Ohio.

Dental Septicemia of the Antrum, by V. A. Latham, Chicago.

Some Facial Deformities and their Prevention, by A. E. Baldwin, Chicago, Ill.

Jaw Movements in Relation to Tooth Forms, by A. H. Thompson, Topeka, Kan.

Irregularities of the Dental Arch, by Eugene S. Talbot, Chicago, Ill.

The Resistance of the Mucous Membranes to Bacterial Infection, by V. A. Gudex, Milwaukee, Wis.

The Morbid Susceptibility of Dental Structures is Greater than that of Other Tissues, by A. H. Sawins, Denver, Colo.

Have We Progressed? by J. M. Porter, Denver, Colo.

SOCIETY NEWS.

Illinois State Medical Society.—For the forty-eighth annual meeting at Galesburg, May 17, 18 and 19, 1898, a rate of one fare and one third on the certificate plan (\$6.50 for the round trip from Chicago) is announced.

Association of Military Surgeons of the United States.—On account of the occupation of the members in connection with the war with Spain, it is announced that the eighth annual meeting, which was to have taken place June 1, 2 and 3 next, is postponed to a date to be fixed hereafter by the Executive Committee. JAMES E. PILCHER, Capt. Med. Dept. U. S. Army, Secretary; J. D. GRIFFITH, Lieut.-Col. and Med. Dir., N. G. Mo., President, Kansas City, Mo.

Association of American Medical Colleges.—The annual meeting of this association will be held at the Brown Palace Hotel, Denver, Colo., Monday, June 6, 1898, beginning at 10 o'clock in the morning. The Judicial Council will meet at the same place at 9:30 A. M. Each college, member of the association, is entitled to one representative and to one vote in all proceedings. The dean of the college is the official representative. When any other person acts in that capacity, he or she should bear an official appointment from the proper officers of the college. At a meeting of representatives of members of the association in Chicago, the following amendments to the Constitution were proposed:

Article III, Section 5 to read after "each course of at least six months duration," and each course of not less than 800 recitation hours, clinical and laboratory hours counting as half hours.

Article III, Section 7. A college not giving the whole four courses of the medical curriculum but otherwise eligible to membership may be admitted to membership the same as if it completed the curriculum and graduated students.

The members of the boards of examiners of the several States and all medical teachers are invited to the morning session and to listen to the president's address in the afternoon. BAYARD HOLMES, 104 E. Fortieth St., Chicago, Secretary.

The American Gastro-Enterological Association.—At the annual session of the American Gastro-Enterological Association held at Washington, D. C., May 3, 1898, the following officers were

elected: President, D. D. Stewart, Philadelphia; first vice-president, Max Einhorn, New York; second vice-president, John C. Hemmeter, Baltimore; secretary and treasurer, Charles D. Aaron, Detroit. Council: Henry L. Elsner, Syracuse; A. P. Buchman, Fort Wayne; Frank P. Murdock, Pittsburgh. The following papers were read:

A Case of Atrophy of the Stomach, with Exhibition of Specimen, by Julius Friedenwald, Baltimore, Md.

a, A case of Acute Pancreatitis; b, Carcinoma of the Cardia, by Morris Manges, New York.

Nervous Dyspepsia, with Report of Cases, by Frank H. Murdock, Pittsburgh, Pa.

a, The Effect of Auto-intoxication on the Liver and Kidneys; b, Exhibition of New Instruments for Intubating the Duodenum and Outlining the Greater Curvature and Colon, by John C. Hemmeter, Baltimore, Md.

Precision of Terms in Diseases of the Stomach, by Chas. D. Aaron, Detroit, Mich.

Ohio State Medical Society.—Resolutions passed.

COLUMBUS, OHIO, May 5, 1898.

To the Editor:—The enclosed report with its recommendations, was adopted today by the Ohio State Medical Society. The immediate publication of it will be a favor, as it will be presented for action at the Denver meeting of the AMERICAN MEDICAL ASSOCIATION. Yours truly,

JNO. A. THOMPSON, Secy.

To the President and Members of the Ohio State Medical Society.

Gentlemen:—Your committee on National Legislation appointed in response to the overture of the New York State Medical Society has awaited the call of the committee of that society for a meeting in Washington to perfect a National organization, but so far no call has been received. Copies of the resolutions of this society anent the Antivivisection Bill of Senator Gallinger, still pending, were sent by your chairman to Dr. Busey, chairman of the District Committee of the District of Columbia, and likewise to Senators Foraker and Hanna. Your committee received a reply from Senator Foraker and a promise to give your request a favorable consideration, but so far received no reply from Senator Hanna. The District Committee, however, caused your resolutions to be printed and placed in the hands of every member of the Senate. Apparently, if we may judge from the circular letter sent out recently by Dr. Howard Kelly of Baltimore, Senator Gallinger is still obstinate in his determination to override the all but unanimous sentiment of the medical profession, and to push the enactment of his mischievous measure into law. But up to this time, owing in no small degree to the efforts of this society, he has not yet succeeded in bringing it to a vote. But the antivivisectionists are persistent; they have ample means and time at their disposal; they have able and influential advocates resident in Washington, and the medical profession must also have its men on the ground, acting with full authority delegated to them in order to counteract the efforts of the so-called humane organizations to hamper and hopelessly cripple biologic and physiologic investigation in the Government laboratories, and in the medical schools of the District of Columbia.

It seemed to your committee last year that the New York plan provided for too large a body, a body which from its very size would prove too unwieldy for prompt and effective work, but the need of a body which shall authoritatively represent the convictions of the organized medical profession upon those matters of legislation, regarding which the medical profession alone has the training requisite to speak with proper authority, become increasingly evident, and your committee beg leave to submit the following plan of organization for the consideration of this society:

1. That the AMERICAN MEDICAL ASSOCIATION be requested to appoint a standing committee of three on National legislation, one member to be a resident of Washington, one of Baltimore and one of Philadelphia. A committee so located could be called together at Washington on short notice and appear before the committees of Congress at any time.

2. That each State society of legally qualified practitioners of medicine be requested to appoint a committee of one on National legislation, such committee to keep himself in communication with the senators and representatives from his own State, so that they may be always kept in touch with the medical profession concerning matters of sanitary and medical legislation.

3. That a joint meeting of the committee of the AMERICAN MEDICAL ASSOCIATION and the committeemen of the several

State societies be held in Washington subject to the call of the Committee of the AMERICAN MEDICAL ASSOCIATION. The purpose of that meeting would be to give opportunity for each State committeeman to personally interview the Representatives and Senators from his own State, and for the committee as a whole or by subcommittees to appear before the various congressional committees to set before them authoritatively the sentiments of the medical profession regarding pending legislation, and to urge the passage of measures upon which the medical profession of the nation have already agreed, and to which they have already given support by formal action. Meeting thus on the ground and consulting together the members of such joint committee would moreover become better cognizant of matters upon which the medical profession ought to take action, and by embodying such matters in their annual reports to their respective societies the sentiment of the medical profession as a whole would become promptly and authoritatively declared. We should thus begin to act as a unit in matters of national legislation affecting the sanitary interests of the people as a whole.

4. That the necessary expenses of these committeemen be borne by their respective societies.

In conclusion, your committee would recommend the adoption of the following resolutions:

Resolved, That we again enter our earnest protest against Senate Bill No. 1063, entitled "A Bill for the Further Prevention of Cruelty to Animals in the District of Columbia," for the reason that existing laws amply provide for the prosecution and punishment of any real cruelty to animals which may be proven to occur within the District, and because the physicians and scientists of the District have not so conducted themselves in the past as to warrant the system of irresponsible espionage authorized by the bill, and further because the paramount interest of the sick and afflicted demands that the medical profession shall have liberty to investigate the nature and treatment of disease free from cumbersome and vexatious restrictions such as are provided in the measure in question.

Resolved, That we again urge upon Congress the necessity of thorough inspection by a medical officer of the United States of all immigrants and their baggage before they embark for this country, in order that the importation of contagious and infectious filth diseases may be more effectually prevented.

Resolved, That the secretary of this Society send a copy of these resolutions to each Senator and Representative in Congress from Ohio, and of the second resolution to the Chairman of the Committee on Commerce and on Immigration of both House and Senate.

Respectfully submitted,
L. B. TUCKERMAN,
RUFUS B. HALL, } Committee.
A. M. BLEILE,

PUBLIC HEALTH.

Non heredity of Tuberculosis.—G. Kuss concludes from extensive research that the immense majority of cases of infantile tuberculosis are acquired after birth by inhaling the germs. The conclusion follows that the children of tuberculous patients should be removed at once after birth from all danger of contagion and brought up in an environment entirely free from tuberculous products.—*Thèse de Paris*, 1898.

Lepers Before the Courts.—A number of lepers in a Russian leprosarium recently attacked and flogged the superintending physician and were summoned to answer at the bar of justice for their criminal assault. But the court and jail officials objected decidedly to their presence and appealed to the higher courts, which decided the unprecedented affair by canceling the summons and leaving the matter to the administration of the institution. *St. Petersburg Med. Woch.*, April 9.

Endemic Pneumonia.—The *Deutsche Med. Woch.* of April 7 contains an account of four cases of extremely malignant lobular pneumonia in a family. The necropsy of one of the three fatal cases disclosed a mixed infection with the streptococcus and bacillus proteus. A parrot in the house was also affected, but no bacteriologic connection between it and the other cases could be established.

Bubonic Plague in Hong Kong.—Advices by the steamer *Columbia* from the Orient as reported from Tacoma, Wash., May 5, bring the current history down to April 6. In the week pre-

vious to the latter date cases in Hong Kong had increased and the colonial government was busy with plans to prevent a spread. A correspondent of the Hong Kong press states that forty new cases were occurring daily. A medical inspection of Chinese coming from Macao and Canton, where smallpox was also prevalent, has been instituted.

Pharmaceutic Advertisements in Non-medical Journals are not allowed in Russia, according to the *Progrès Méd.* No specialty can be advertised except in the medical press. A recent decree in Germany places "secret medicines" under the same regulations as poisons. The name, price, composition and maker must be plainly indicated; no testimonials, etc., are allowed on the bottle or wrapper. The administration reserves the right to prohibit the sale of certain remedies and establish a maximum price. Similar regulations are already in force in Russia.

How Long Will Diphtheria Serum Retain its efficiency was discussed by Aaser of Norway (*vide JOURNAL*, page 1060), and his conclusions for that cold climate have been practically confirmed by Abba of Turin, who states that the shortest period is a year and a half. It is not affected by light nor temperature, and some specimens retained their efficiency three years, but as a general rule it can be injected with confidence under a year and a half, without regard to changes in its color or transparency.—*Gazz. degli Osp.*, February.

NECROLOGY.

DAVID W. YANDELL, M.D., died at his residence in Louisville, Ky., May 2, at 10 o'clock, P.M. He was taken seriously ill about four years ago, never having been out of the house since

DAVID W. YANDELL, M.D.

that time, his end coming peacefully, surrounded by his family. Dr. Yandell was born in Tennessee, at Craggy Bluff, six miles from Murfreesboro, Sept. 12, 1826. This was near the spot afterward made memorable by one of the bloodiest battles of the civil war. His mother was a Miss Waddell and his father Dr. Lunsford P. Yandell, one of the leading physicians of Louisville and a professor in Transylvania University at Lexington, Ky. In 1831 Dr. L. P. Yandell moved to Lexington, where he remained until 1837, when he came to Louisville and

founded the Louisville Medical Institute. The subject of this sketch studied under various teachers in Louisville and Lexington and afterward at Center College, Danville, graduating in medicine at the University of Louisville in 1846. In the fall of the same year he sailed for Paris, and studied medicine there for three years. In 1849 he returned to Louisville, but as his health failed he went to farming near Nashville, Tenn., and began the practice of his profession in Louisville three years later. He established the Stoke's Dispensary and conducted private classes in medicine for several years. In 1867 he was appointed professor in the University of Louisville, of the science and practice of medicine. He retained this chair but one year, when he resigned, but in 1869 he was elected to the chair of surgery and clinical surgery, which chair he occupied until his death. In conjunction with Dr. Parvin of the University he established the *American Practitioner*, which was afterward amalgamated with the *Louisville Medical News* under the name of the *American Practitioner and News*. Dr. Yandell was editor in chief and Dr. H. A. Cottell associate editor. The AMERICAN MEDICAL ASSOCIATION chose Dr. Yandell as its President in 1871, the year it met in Louisville. Dr. Yandell was a member of AMERICAN MEDICAL ASSOCIATION, the American Surgical Association, the Kentucky State Medical Society and all the local societies. He was a fine lecturer and held in the highest esteem by the members of his classes. Although he was not a church member he had the greatest reverence for religion and always endeavored to impress the same ideas on his pupils. His reputation as a surgeon was not acquired by any one remarkable operation but by close and diligent application to his chosen profession. In the fall of 1861 Dr. Yandell enlisted as medical director under Albert Sidney Johnston at Bowling Green, Ky., and continued with him to the time of Johnston's death at Shiloh, April 6, 1862. After General Johnston's death Dr. Yandell was appointed medical director on the staff of Gen. W. G. Hardee, and was with him at the battles of Perryville, Murfreesboro and Chickamauga. He remained with General Hardee until 1864, when he was transferred to the trans-Mississippi department, at his own request, under Gen. Kirby Smith, with whose command he remained until the end of the war. Dr. Yandell was a leader in all public movements. He took a great interest in the Louisville Legion and was its medical director for many years prior to his death. He was a great friend and admirer of Joseph Jefferson, the actor. He was a member of the Pendennis, Filson and Salmagundi Clubs and had many good friends among the rich and poor alike. He was a fine sportsman and owned some very fine dogs, although he did not devote very much time to their breeding. He cared more for the dog's ability to find birds than he did for its pedigree. Not many months passed without the Doctor taking a little time and spending a few days in the country hunting. Dr. Yandell was a man of commanding presence and great ability. He was of rough exterior, plain spoken at times almost to the verge of harshness, his rugged bosom encased a heart whose pulsations were all tenderness for the suffering and distressed. Successful as a physician and surgeon he amassed a handsome competence and his purse was always open to the needy. He married Miss Frances Crutcher of Nashville, who survives him, with two daughters, Maria, the wife of Dr. W. O. Roberts, and Susan, Mrs. Jas. F. Buckner. He has one brother, a physician in El Paso, Texas.

ISAAC NEWTON QUIMBY, M.D., New York University Medical College, 1859, member of the AMERICAN MEDICAL ASSOCIATION, the Gynecological Society of Boston, Mass., Society of Medical Jurisprudence of the Hudson County (N. J.) District Medical Society and a frequent delegate to State medical societies, died at his home in Jersey City, N. J., May 6. He was an active participator in medical debates, a writer of practical papers and at the time of his death was president of the staff of the Jersey City Hospital. Dr. Quimby was born Aug. 5, 1831, and left an orphan at an early age. In 1859 he gradu-

ated from his college with a special certificate of honor. On the breaking out of the civil war he entered the army as a volunteer surgeon, served with General McClellan's forces in the swamps of the Chickahominy and in the Seven Days' Battle. He was also at Antietam, remaining with his division until after the battles of the Wilderness. He was the originator of the Hudson County, now Christ's, Hospital in 1868, and surgeon to the same until 1873. He was one of the founders and the first chairman of the Section on Medical Jurisprudence of the AMERICAN MEDICAL ASSOCIATION. He was also a member of the American Public Health Association, the Medico-Legal Society of New York, the Mississippi Valley Medical Association, member of the British Medical Association, of the American Association for the Cure of Inebriety, a delegate from the AMERICAN MEDICAL ASSOCIATION to the International Medical Congress, London, 1881, again in 1884, in Copenhagen, and again in 1894, at Rome, Italy, and a member of the First Pan-American Medical Congress, which met at Washington, D. C., in September, 1893. Dr. Quimby has devised several important improvements in surgical operations, reported in the "Transactions of the AMERICAN MEDICAL ASSOCIATION," and was one of the founders of the American

ISAAC NEWTON QUIMBY, M.D.

Medical Temperance Association in 1891, vice president in 1891. At a special meeting of the staff of the Jersey City Hospital, May 7, 1898, the following resolutions were unanimously adopted:

WHEREAS, Dr. Isaac N. Quimby, for so many years a member of the Jersey City Hospital Staff, has been removed by death, therefore be it

Resolved, That we, the members of the staff, fully realize how great is our loss in being deprived for all future time of the kindly counsel and companionship of our late associate, Dr. Isaac N. Quimby, that we feel that by his death, not only among ourselves, but in the community at large, a vacancy has been created which can not easily be filled. That we tender to his family our most sincere sympathy in their sad bereavement. That a copy of these resolutions be sent to the daily papers of the city and to the prominent medical journals of the country.

PETER GUNTERMAN, M.D., died May 1 after a brief illness. Dr. Gunterman was born in Germany, fifty-five years ago, received his early education there, and when a young man came to this country and was for several years one of the instructors in the Gethsemane Seminary near Bardstown, Ky., a Roman Catholic monastery. He entered the University of Louisville where he was graduated in 1869, beginning the practice of his profession at once in a little town in Indiana,

where he remained for five years, then removed to Louisville, where he practiced his profession continuously to the time of his death. He was a member of the Louisville Clinical Society for a number of years and has contributed some valuable articles at various times at its meetings. He was genial, courteous, kind and a most excellent friend, and his many friends mourn his untimely death.

CHARLES STORCK, M.D., Chicago, died May 6. He was born June 9, 1826, in the Grand Duchy of Baden, won distinction as a captain of engineers in the revolution of 1848, came to this country in 1851, and received his medical degree in 1855 at Albany, N. Y. He served as a surgeon in the civil war until symptoms of heart trouble obliged him to retire from service.

ALBERT BROWNELL WORTHINGTON, M.D., Middle Haddam, Conn., April 26, aged 79 years.—D. C. Durham, M.D. Anoka, Minn., May 20.

MISCELLANY.

The Bacillus Icteroides is said to be one of the most actively pathogenic germs yet discovered. Foa's tests with the serum furnished by Sanarelli confirm the latter's statements in every particular.—*Gazz. d. Osp.*, February.

The Cure of a Congenital Goiter in a Nursling, by thyroid medication taken by the mother, is reported by Mosse. The child showed the effects of the treatment more promptly than the mother—*Bull. de l'Acad. de Méd.*, April 12.

A Tumor in the Femur resembling the structure of the thyroid gland was recently removed by Goebel from a woman of 54 years, who had had femoral hernia twice and pseudo-arthritis. This makes the sixteenth case of struma metastasis on record.—*Munch. Med. Woch.*, April 12.

The University of Michigan a Beneficiary.—Dr. Elizabeth H. Bates, who died recently at Port Chester, N. Y., has bequeathed property worth \$135,000 to the University of Michigan at Ann Arbor. The bequest is to yield \$6000 per annum with a view of establishing a professorship for the diseases of women and children.

The Typhoid Bacillus and Arsenious Acid.—Another means of distinguishing between Eberth's bacillus and the bac. coli is that the former will not develop in peptonized bouillon to which one centigram per thousand of arsenious acid has been added, while the bac. coli grows readily in the same containing even as much as one and a half grams of arsenious acid.—*Bull. de la Soc. Méd. des Hôpitaux*, March 24.

Army Surgeons.—The bill (H. R. 9638) to increase the number of surgeons in the United States Army, was passed by the Senate May 6. It is as follows:

Be it enacted, etc., That the number of medical officers of the Army be increased by the addition of fifteen assistant surgeons with the rank of first lieutenant, to be appointed by an Army medical examining board, in accordance with existing regulations.

Sec. 2. That in emergencies the Surgeon-General of the Army, with the approval of the Secretary of War, may appoint as many contract surgeons as may be necessary, at a compensation not to exceed \$150 per month.

Radiography of the Stomach.—By mixing bismuth subnitricum with the food and beverages, Roux and Balthazard have succeeded in watching the contractions and action of the stomach during digestion, with the fluoroscope, and taking a series of radiographs of the entire process, in dogs.—*Deu. med. Woch.*, April 7, from *Arch. de Phys.*, x, p. 85.

Dr. Samuel H. Durgin Re-elected.—At a recent meeting, the Boston Board of Health organized by re-election of Dr. Samuel H. Durgin as chairman and Charles E. Davis, Jr., as secretary of the board. Commissioner Edwin L. Pillsbury, whose term of office expired on April 30, holds over until the election of a successor. He is a candidate for re-appointment.

The New Keratin Treatment for Syphilis. De Lalande reports that he has treated thirty syphilitics during the last two years

with a solution made of calves' horns pulverized, 60: chlorid of sodium, 10, and distilled water, 1000, injected subcutaneously, curing every case with from ten to thirty injections, and no relapses to date. He ascribes the effect to a combined sero- and opo-therapeutic action. Full particulars are given in the *Presse Méd.* of March 12.

Compensatory Hypertrophy of the Suprarenals.—Simmonds has observed a case in which one suprarenal, histologically normal, weighed 15 grams and the other, tuberculous, only 2. He has produced a similar compensatory hypertrophy in young animals, but his experiments on older animals were negative, which suggests an explanation of the few instances of this hypertrophy noted at necropsies.—*Munch. Med. Woch.*, April 12.

Diphtheria Antitoxin per Os.—Zahorsky (*N. Y. Med. Jour.*, March 19) reports results from a study of diphtheria antitoxin administered by the mouth. He found the great objection to its ingestion was its slow absorption, its effect not being noticed for from twenty-eight to thirty-six hours. The sequelæ by this method are similar to those produced by its subcutaneous use, but joint pains, erythema, urticaria and dysmenorrhea are not prevented. Its absorption is sometimes delayed or wanting, making this method less reliable than the subcutaneous. It should therefore be given by mouth only in exceptional cases, in mild cases in adults, or for prophylactic purposes when it should be the preferable method. In the issue of April 9, Fisch reports experiments which confirm the slow absorption of antitoxin given by mouth, but he asserts that for prophylactic purposes it should be thus employed only with careful discrimination of the conditions.

A Permanent Home for the Paris Académie de Médecine is now assured, as the government has recently appropriated about \$300,000 to erect a suitable building, rue Bonaparte. The rich library and collections of the Académie, containing 180,000 published works, portraits of 6000 physicians, priceless MSS., etc., are exposed to danger from fire in the old chapel of the Charité where the Académie has been installed since 1850. The Académie has agreed to return one-third of the amount, having nearly enough bequests already on hand for the purpose.

The Criminal Insane.—In the *Medical Record* for April 9, Williams gives some statistics on this subject. He finds that during the past twenty-five years, 459 murderers have been apprehended in New York State, and of that number 40 per cent. have been confined in insane asylums since their crimes were committed, while 30 per cent. were insane at the time of their crimes. Again, fully 20 per cent. of all the murderers apprehended should, long before their crimes were committed, have been confined where they could do no harm, their mental aberrations being so pronounced. He says the prison records show the average length of confinement, including life sentences, is but a little over two years, while the average confinement in insane asylums is over four years.

Colleges.

HARVARD UNIVERSITY, WASHINGTON, D. C., graduated thirty-two from the Medical Department, May 6.—At the eighth annual commencement of Laura Memorial College, Boston, there were seven graduates.—The graduating class of the St. Louis Medical College numbered twenty-eight, April 29.—Creighton Medical College, Omaha, Neb., had a graduating class of fifteen.—The College of Physicians of Philadelphia is to receive \$1000, a bequest from the late Oliver A. Judson.

Boston.

SUFFOLK DISTRICT MEDICAL SOCIETY.—At the last annual meeting of the Suffolk District Medical Society, held April 20 1898, the following officers were elected: President, Francis H. Brown; vice-president, Herbert L. Burrell; secretary, John Dane; treasurer, Augustus L. Knight; Librarian, B. Jo. Jeffries.

APPOINTMENT.—Dr. Fred M. Briggs has been appointed Professor of Clinical Surgery at Tuft's College Medical School.

THE WARREN TRIENNIAL PRIZE has been awarded to Dr. Howard Ames Lathrop of Boston, for an essay on "The Anatomy and Surgery of the Frontal Sinus and Anterior Ethmoidal Cells."

N. E. PHYSICIANS AT THE DENVER MEETING.—The prospects are that a large number of New England physicians will avail themselves of the opportunity to visit the great West by attending the meeting of the AMERICAN MEDICAL ASSOCIATION at Denver. Dr. R. E. Campbell of Bellows Falls, Vt., is secretary of the New England Railroad Committee of Arrangements.

THE SHARON SANITARIUM.—The report of the seventh year of Sharon Sanitarium for pulmonary diseases is favorable to the methods employed in that institution. The results show, according to the report, that "incipient consumption can be arrested in a large percentage of cases even in the vicinity of Boston." An appeal is made for funds to enlarge the institution and thereby increase its usefulness.

VALUABLE PUBLICATION.—The Massachusetts State Board of Health has recently issued a publication on "Epidemic Cerebrospinal Meningitis and its Relation to other Forms of Meningitis." It was compiled under the direction of Drs. Councilman, Mallory and Wright, and is the result of a clinical and pathologic investigation of 111 cases made by these gentlemen. Many new facts are brought out in the book, and it is believed to be really a valuable acquisition to medical literature.

Washington.

HEALTH OF THE DISTRICT.—The report of Health Officer Woodward for the week ended April 30, shows the total number of deaths to have been 90, of which 49 were white and 41 colored. The principal causes of death were: Diseases of the lungs, 24; diseases of the nervous system, 19; one death each from diphtheria and scarlet fever and two from whooping-cough. There were 32 cases of diphtheria and 46 cases of scarlet fever under treatment at the close of the week.

TO REGULATE POSSESSION OF DEADLY WEAPONS.—The Senate has passed House Bill 5885 recommended by the commissioners, regulating the carrying and sale of deadly weapons in the District of Columbia.

MARINE HOSPITALS.—The President has approved an order directing the use of any and all Marine Hospitals for the treatment and reception of sailors and soldiers of the army and navy whenever a necessity therefor arises. This was a superfluous order, as the regulations have provided for this for many years past.

PUBLIC VEHICLES TO BE REGULATED.—The Health Office is to be congratulated on discovering a law still in force, which permits that department to condemn or render sanitary any public vehicle used in the District, when such are found to be unclean or a menace to health. The physicians who are compelled to employ the "night liners" have been complaining for a long time of the filthy and disgraceful condition of many of these moving pest disease-spreaders, masquerading as vehicles.

CENTRAL DISPENSARY AND EMERGENCY HOSPITAL. At the annual meeting of the Board of Directors held on the 6th instant for the election of officers, the following were chosen: President, W. J. Boardman; vice-president, Henry F. Blount; secretary, W. C. Whitmore; treasurer, Hon. John B. Wight. Mrs. Senator Hawley reported that her committee of ladies expected very shortly to be able to have sufficient funds on hand to reconstruct and modernize the general operating room of the hospital.

PHYSICIAN TO THE WHITE HOUSE.—Surgeon-General George M. Sternberg, President of the AMERICAN MEDICAL ASSOCIATION is now the attending physician at the White House. Col. Wood, the former physician, will be stationed at San Antonio, Texas, with his regiment.

MEDICAL SOCIETY. At the meeting of the Society held on the 4th instant, Surgeon S. L. Allen read the essay of the evening entitled "Acute Hemorrhagic Encephalitis." Dr. Stone presented some interesting cases and specimens.

WASHINGTON OBSTETRICAL AND GYNECOLOGICAL SOCIETY.—At the two hundred and eighty-first meeting of the Society held on the 6th instant, Dr. Stone read a paper on Grauert's operation for relaxed vaginal outlet and lacerations of the perineum. Dr. Bovee presented a specimen of fibroma uteri.

Philadelphia.

DR. JOHN GUITERAS HONORED.—Dr. John Guiteras, professor of pathology in the University of Pennsylvania, and a

prominent member of the Cuban junta in this country, has been summoned by the Government to report at Tampa, Fla., where he goes on duty as an expert on tropical diseases, and to give proper instruction to the United States troops relative to the prevention of the introduction of yellow fever into the United States as well as to instruct the troops of proper precautions to be used to prevent the disease while on the island of Cuba. His lectures have closed at the University and it is possible that his new duties will keep him away until the fall session begins. It will be remembered that Dr. Guiteras was called south last year during the epidemic of yellow fever, as authority on this disease.

REQUEST TO THE COLLEGE OF PHYSICIANS OF PHILADELPHIA.—By the will of the late Dr. Oliver A. Judson of Philadelphia, the College of Physicians will receive \$1000 to be held in perpetuity. A clause in the will stipulates that: "As often as the interest on the same shall amount to \$100 the same is to be offered as a prize for the best original essay on 'The Practical Prevention of Disease,' and to be known as the 'Oliver A. Judson prize,' and need not be awarded if no essay merits it." In this way it is hoped to stimulate investigation in this special branch of medicine.

APPOINTMENT FOR DR. WILLIAM PEPPER.—The Adjutant General of the United States Army recently advised Governor Hastings of the necessary physical examinations requisite before volunteers would be permitted to join a State encampment. An army surgeon and two civilian physicians will constitute such a board of examiners for the State of Pennsylvania. Governor Hastings has therefore appointed Dr. William Pepper of Philadelphia and Dr. W. S. Foster of Pittsburgh, to conduct such examination on the part of physicians. In this way it is hoped to restrain those who are physically disabled from joining the militia.

PHILADELPHIA MORTALITY STATISTICS.—For the week ending Saturday, April 30, there was an increase of forty-five deaths over the previous week, the total number of deaths being 472. Of this number there were from scarlet fever, 4; diphtheria, 16; typhoid fever, 6; as against 2, 13 and 6 respectively for the week preceding.

Louisville.

ORDINANCES.—Health Officer Allen has introduced an ordinance regulating the sale of milk, which has passed one branch of the general council and will be favorably reported by the Committee on Health of the upper board. Its exactions are as follows: The name of the dairyman must be placed conspicuously on the dairy wagons and in the store where milk is sold; defines good milk and prohibits its adulteration; cows must not be fed on swill, slop or other fermented foods; cows must not be crowded, must be kept clean; must be healthy and must be inspected by a veterinary surgeon every three months; samples of milk must be furnished the city health department whenever demanded. An ordinance was also passed regulating the collection and disposal of garbage or trash, making it unlawful not to have tarpaulins or covering to wagons. An ordinance was also introduced providing for an "embalming board" for licensing only competent embalmers. This board to consist of the president of the Board of Public Safety, the health officer, a competent embalmer, the Jefferson County referee of the State Board of Health and the coroner of Jefferson County. The ordinance was passed in one board and referred to the other for consideration.

STATE GUARD.—There seem to be several hitches in the appointment of surgeons to the various regiments of the State Guard ordered into camp at Lexington. Deputy United States Surgeon-General W. K. Gardner is in charge of the examinations, with a board appointed by the governor. Drs. David Barrow and B. S. Coleman were at first appointed but resigned. Drs. W. B. McClure and Archie Barclay were appointed in their stead. Drs. Charles Farmer and R. N. Winn were passed for surgeons of the Second Regiment. Drs. E. L. Pearce, Irvin Lindenberger and Brent Palmer of Louisville for First Regiment, Dr. Waller Dade, formerly of Frankfort, and now of Chicago, and Dr. Grinstead of Bowling Green will also appear before the board.

BULLOCK. Dr. Thomas S. Bullock has returned from Arkansas fully restored to health.

KENTUCKY SCHOOL OF MEDICINE. The following members of the faculty, Drs. J. M. Holloway, J. M. Mathews, J. B.

Marvin, C. W. Kelly and S. E. Woody have filed suit in the law and equity court against Drs. W. H. Wathen, M. F. Coomes and Henry Orendorf to compel them to dispose of their share in said school. This suit is the culmination of an effort on the part of the majority more than a year ago to displace the three men mentioned as members of the faculty.

THE COUNTY BOARD OF HEALTH met at the office of Dr. W. H. Wathen, the Referee of the State Board of Health for Jefferson County, and organized by electing the following officers: George W. Griffiths, president; J. M. Krim, secretary; B. M. Smock, sanitary inspector. The board adopted the rules and regulations of the State Board and, as now organized, has under the statutes of the State full authority to abate nuisances or all conditions prejudicial to the health and happiness of the people and to enforce regulations in the interest of health and the prevention of disease, such as vaccination, etc.

THE PUBLIC SERVICE.

Circular Letter.

WAR DEPARTMENT, SURGEON-GENERAL'S OFFICE,
WASHINGTON, D. C., April 25, 1898.

The number of physicians who have offered their services to the Government now exceeds 1500, and every mail brings numerous additions to the list.

The Surgeon-General highly appreciates the patriotic motives which have induced this offer of services—in many instances by men prominent in the profession and enjoying a lucrative practice—but the labor of answering these numerous letters interferes with the necessary work of the office, which has been greatly increased by the exigencies connected with equipping the Regular and Volunteer Armies for field service. It therefore becomes necessary to acknowledge letters offering service and inquiries relating to the Medical Department by this circular letter.

No appointments are made in the Regular Army except after examination by an Army Medical Examining Board, and all applicants must be graduates in medicine and less than 29 years of age.

The Surgeon-General of the Army has nothing to do with the appointment of medical officers for the Volunteer Army.

Comparatively few Contract Surgeons (Acting Assistant Surgeons) are likely to be required, and it is the intention to employ for service with troops going to Cuba or at hospitals on the Gulf Coast, only such as are immune to yellow fever.

All applications and offers of service will be placed on file for future reference, and for selection of the most available persons for the special duty required, in case of need.

No female nurses will be sent to Cuba or to hospitals on the Gulf Coast, and it appears probable, at present, that there will be no necessity for the employment of trained female nurses. All applications will, however, be placed on file for future reference in case of need.

GEO. M. STERNBERG,
Surgeon-General, U. S. Army.

Army Medical Examining Board.

The scope of the competitive examination for admission into the Medical Department of the Army has been extended, under the direction of the Surgeon-General, by the Army Board now in session in Washington, D. C. The number of subjects has not been increased, but so much more time is now given to oral examination in each subject so that the ordeal lasts ten days instead of being finished in six. Formerly that the oral part was disposed of daily, one in a forenoon, the other in an afternoon session, but now one whole day is devoted to each of the two principal branches. Formerly also the examination began with an inquiry into the general education of the candidates, including arithmetic, geography, history and general literature, but now these subjects are brought in at the close of the competitive trial. This change appears to have been made in the interest of men who, while well versed in professional matters, have permitted themselves to lapse into forgetfulness of their early school branches. When the preliminary examination, as it was called, into general education came first, such men were likely to lose heart on account of their appreciation of their own shortcomings, and to withdraw from the competition before they had an opportunity of showing the strong points of their education and training.

Army Changes. Official List of Changes in the Stations and duties of officers serving in the Medical Department, U. S. Army, from April 30 to May 6, 1898.

Acting Asst. Surgeon Francis Lieber, U. S. A., will proceed from this city, Washington, D. C., to Ft. Clinch, Bernardino, Fla., and report in person to the commanding officer of that post for duty.

Major Louis Brechemin, Surgeon, is relieved from duty at Ft. Sherman, Idaho, and ordered to Vancouver Bks., Washington, for duty, relieving Capt. Frederick P. Reynolds, Asst. Surgeon. Capt. Reynolds, on being thus relieved, will report to Washington, D. C., without delay, and report in person to the Surgeon-General of the Army for assignment to duty.

Acting Asst. Surgeon H. W. Danforth, U. S. A., will proceed from Washington, D. C., to Tampa, Fla., and report in person to the commanding General of the troops at that place for duty.

Acting Asst. Surgeons John Gultéras and W. W. Calhoun, U. S. A., will proceed from Washington, D. C., to Tampa, Fla., and report in person for duty to the commanding General of the U. S. troops at that place.

Col. Charles R. Greenleaf, Asst. Surgeon General, having reported in person to the Surgeon-General of the Army, the Secretary of War directs that he report in person to the Major-General commanding the Army, for duty on his staff as chief surgeon of the troops in the field.

Capt. Edward C. Carter, Asst. Surgeon, having reported in person to the Surgeon-General of the Army, is assigned to duty as assistant to the attending surgeon, Washington, D. C.

First Lieut. James S. Wilson, Asst. Surgeon, will be relieved from duty at Ft. Caswell, N. C., upon the arrival at that post of Acting Asst. Surgeon Frank Roberts, and will report in person for duty to the commanding General of the troops in the field at Chickamauga National Park.

Major Alfred C. Girard, Surgeon, having reported to the Surgeon-General of the Army, will proceed to West Point, N. Y., and report in person to the superintendent of the U. S. Military Academy for temporary duty at that post.

Major George H. Torney, Surgeon, is relieved from duty at the U. S. Military Academy, West Point, N. Y., to take effect upon the arrival at that post of Major Girard, and will proceed to New York City and take charge of the hospital ship "Vigilancia," under detailed instructions from the Surgeon-General.

Capt. Charles Willcox, Asst. Surgeon, is relieved from duty at Ft. Bliss, Texas, and ordered to report in person to the commanding General of troops in the field at Mobile, Ala.

Major William B. Davis, Surgeon, is relieved from duty with the Nineteenth Infantry at Mobile, Ala., and ordered to Ft. Myer, Va., for temporary duty.

First Lieut. William E. Richards, Asst. Surgeon, is relieved from duty at Ft. Apache, Ariz., to take effect upon the arrival at that post of Capt. Edward Everts, Asst. Surgeon, and will report in person to Major General John R. Brooke, commanding Camp George H. Thomas, Chickamauga National Park, for duty with troops in the field.

CHANGE OF ADDRESS.

Ammerman, N. S., from Harbino to Reynold, Neb.
Boren, S. L., from Galveston to Carthage, Tex.
Boyer, J. S., from Chicago, Ill., to Richardville, Va.
Brown, E. V. L., from 268 S. Wood St. to 349 Ogden Ave., Chicago, Ill.
Chapman, C. F., from 594 Washington Boul. to 583 Washington Boul., Chicago, Ill.
Cox, J. E., from Los Angeles to Big Pine, Cal.
Dulaney, R. W., from Johnson City to Jonesboro, Tenn.
Engert, R. H., from Venetian Bldg. to 486 N. Clark St., Chicago, Ill.
Farris, J. W., from St. Louis to Caruthersville, Mo.
Fisher, B. B., from 2220 Walnut St. to 1095 1/2 3d Ave., Milwaukee, Wis.
Frederick, R. C., from Chicago, Ill., to Pte. Coupee, La.
Garrett, G. H., from Blue, Ind. Ter., to Miller Grove, Tex.
Gibson, G. G., from Des Moines to Odebolt, Iowa.
Grasse, D. F., from Chicago, Ill., to Fargo, N. D.
Guernard, A. R., from New York, N. Y., to Flat Rock, N. C.
Hayford, E. L., from 843 Jackson Boul. to 926 W. Monroe St., Chicago, Ill.
Hamill, E., from 323 S. Western Ave. to 812 Warren Ave., Chicago, Ill.
Howard, R. E., from New York, N. Y., to Kasheer, Ill.
Jenney, E. L. B., from 1780 Wrightwood Ave. to 1033 Evanston Ave., Chicago, Ill.
Jones, C. C., from Galveston to Brock, Tex.
Johnson, C. J., from 663 Jackson Boul. to 522 Congress St., Chicago, Ill.
Kidd, O. R., from Hampton to Carrsville, Ky.
Kiebs, E., from Hotel Majestic to 4119 Indiana Ave., Chicago, Ill.
Langdon, C. P., from Columbus to Westerville, Ohio.
Law, H. L., from Hartford, Conn., to U. S. R. S. "Wabash," Boston Navy Yard, Boston, Mass.
Maylor, H., from 805 W. Broadway to 1517 Southgate St., Louisville, Ky.
Mayhew, J. M., from 1393 Lake St. to 870 Warren Ave., Chicago, Ill.
McDanill, R., from Galveston to Granger, Tex.
McGauran, G. D., from 422 to 319 W. 51st St.
Meyer, A. G., from St. Louis to Ste. Genevieve, Mo.
Mitchell, G. D., from 1840 N. Clark St. to 7033 Honore St., Chicago, Ill.
Miller, Y. Y., from Linn Grove to Brown's Grove, Ky.
Mook, J. H., from Richmond, Va., to Thomasville, N. C.
Nance, W. O., from 5466 Monroe Ave. to 5311 Madison Ave., Chicago, Ill.
Nicoll, D. T., from Kilbourn City, Wis., to Clinton, Iowa.
Nolder, S. M., from Newton, Kan., to Tipton, Ind.
Paine, H. M., from Glens Falls, N. Y., to West Newton, Mass.
Pence, L. W., from Fertile, Iowa, to Cherryvale, Kans.
Pennock, V. R., from Longmont to Cripple Creek, Colo.
Rowe, J., from Abingdon to Hos. Dept., 1st Cav., Camp Tanner, Springfield, Ill.

CHICAGO, ILLINOIS, MAY 21, 1898.

No. 21.

ADDRESS.

THE SURGICAL TREATMENT OF INTESTINAL TUBERCULOSIS.

Delivered at the Meeting of the Illinois State Medical Society, held at Galesburg, May 17, 1898.

BY N. SENN, M.D., Ph.D., LL.D.

Professor of Practice of Surgery and Clinical Surgery in Rush Medical College; Professor of Surgery Chicago Policlinic; Attending Surgeon Presbyterian Hospital; Surgeon-in Chief St. Joseph's Hospital.
CHICAGO, ILL.

The title of this paper will probably appear somewhat strange and out of place to the general practitioner and the surgeons who have not kept fully abreast with the great advancements that have been made during the last decade in the diagnosis and surgical treatment of localized lesions of the intestinal tract. Our increased knowledge of the location, nature and clinical tendencies of accessible tubercular affections has opened a wide and fertile field for successful surgical intervention. There is hardly an organ in the body which when the seat of a localized tubercular process has not been exposed and subjected to direct treatment with a fair expectation of removing or limiting the further extension of the disease. The medical treatment of tuberculosis in its various forms at the present time is not much in advance of that of fifty years ago. The numerous specifics invented and vaunted in different parts of the world have all fallen by the wayside and the old-fashioned remedies are again taking their place. Leaving out the local measures we have to rely in the treatment of such cases largely on diet, change of climate and occupation, outdoor air and the administration of those remedies known to exercise a favorable influence in improving digestion, nutrition and assimilation, and thus indirectly antagonize the ravages of the disease.

Powerless as we remain today in the successful systematic treatment of tuberculosis, it is a source of gratification to know that great improvements have been made in the local treatment of accessible tubercular lesions. The intestinal canal is one of the last territories opened up for successful surgical invasion. All the work done in this department of surgery dates back but a few years. The results obtained by the surgical treatment of localized intestinal tuberculosis are such as to encourage further effort in this direction. The number of cases operated upon so far remains a small one, and it is my intention on this occasion to bring them to the attention of the profession of this country and to describe the different operative procedures which have been employed by different operators with the same aim in view, either to remove the diseased tissue, or to render the affected portion of the bowel accessible to direct treatment, or to place it in a more favorable condition for spontaneous healing of the tubercular ulcers.

This paper will deal largely with localized primary

tuberculosis of the intestinal canal, with cases amenable to successful surgical treatment. Diffuse primary tuberculosis of the intestines remains, for the present, a surgical *noli me tangere*. Surgical intervention is also contraindicated in secondary intestinal tuberculosis in all cases in which the primary disease, usually pulmonary tuberculosis, is far advanced and constitutes in itself an imminent source of danger to life. There are, however, cases of primary intestinal tuberculosis in which timely radical measures prove successful in eliminating the disease permanently and in restoring normal intestinal digestion and absorption. The attention of the mass of the profession must be called to the necessity of a more careful and thorough examination of chronic inflammatory affections of the intestinal tract, for the purpose of making an early and correct diagnosis and with a view of selecting appropriate cases for timely surgical treatment. The internist and the surgeon must co-operate with each other in the future development of this, one of the most recent departments of the healing art.

I shall quote and describe the cases operated upon for intestinal tuberculosis under the headings of the different operative procedures:

1. *Abdominal section and iodoformigation.*—Every surgeon is familiar with the curative effects of abdominal section and drainage, with or without iodoformigation, in cases of peritoneal tuberculosis. The modus operandi of this method of treatment has never been fully and satisfactorily explained, but the fact remains that it has proved eminently successful in the majority of such cases. There is no doubt in my mind that the local application of iodoform adds to the therapeutic value of this method of treatment. In one of the cases which has recently come under the observation of the writer abdominal section and drainage were resorted to on two different occasions, but the tubercular hydrops returned. Tapping and the injection of from 7.4 to 15 c.c. of a 3 per cent. of iodoform-glycerin emulsion repeated six or eight times at intervals of from one to two weeks finally succeeded in effecting a cure, and the patient remains in perfect health, more than a year after the last tapping. Future observations will undoubtedly prove that peritoneal tuberculosis is more frequently caused by infection from primary intestinal lesions than has been heretofore supposed.

It is not strange that the same treatment should occasionally prove equally useful and efficient in certain cases of intestinal as in peritoneal tuberculosis. Nové-Josséraud ("Tuberculose localisée du cæcum traitée par la simple laparotomie," Société des Sciences Médicales de Lyon. *Lyon Médicale*, 1896, No. 22) made a laparotomy on a child 12 years old for a swelling the size of an adult's fist in the region of the cæcum. The incision demonstrated the existence of extensive tuberculosis of the cæcum and adjacent portions of the ileum and ascending colon. The affected parts were not interfered with, except that they were wiped gently

with iodoform gauze and dusted with a thin film of iodoform, and yet the operation was followed by a speedy and permanent recovery.

This method of treatment has a limited application in the treatment of intestinal tuberculosis when the disease is too extensive for more radical measures and no obstructive lesion is indicated by the symptoms or discovered at the time of operation. Iodofumigation and capillary drainage with iodoform gauze for a few days would seem to be indicated in such cases.

2. *Enteroplasty*.—Plastic operations are indicated in solitary circular strictures following the healing of a tubercular ulcer and constituting the cause of intestinal obstruction. In narrow circular strictures an operation similar to that devised by Heineke-Mikulicz for pyloric cicatricial stenosis will yield the most satisfactory operative and functional results. The stricture is divided on the convex side of the bowel and the incision carried sufficiently far into healthy tissues on each side of the stricture, in a direction parallel to the long axis of the bowel, and the visceral wound closed transversely by two rows of sutures of fine braided silk, thus restoring the lumen of the bowel to its normal size.

Péan (*Bulletin de l'Académie de Médecin*, Dec. 30, 1890) performed such an operation for cicatricial stenosis of the ileo-cecal valve, following the healing of a tubercular ulcer. He made the abdominal incision above and parallel to Poupart's ligament. The bowel was tied above and below the constriction with a rubber cord passed through a slit in the mesentery. The intestinal wall was incised at the level of and at each side of the strictured valve for a distance of three inches. After washing out the opened segment of the bowel with a 1 per cent. solution of carbolic acid, the cicatricial tissue was excised. This being done, the two extremities of the intestinal wound were brought together by means of forceps. The incision, which was first longitudinal, soon took the form of a lozenge, two sides of which were represented by the lips of the small intestine and the other two by those of the large intestine. Bringing the forceps nearer together the incision became transverse, and in this position the edges were sutured in the usual way. Catgut was used for the inner and silk for the outer row of suturing. The patient recovered and remained in good health at the time the report was made.

3. *Enterectomy*.—The most radical treatment of intestinal tuberculosis, in appropriate cases, is resection followed by circular suturing. Resection is indicated in isolated intestinal tuberculosis as long as the swelling is movable and the disease gives rise to symptoms of obstruction: if, however, the disease is no longer limited to the organ primarily affected, or if it is complicated by advanced pulmonary or general tuberculosis entero-anastomosis should take the place of a radical operation. Experience has shown that it is neither essential or even necessary to add to the gravity of the operation by attempts to remove the products of regional infection. After removal of the primary focus of infection the lymphatic tuberculosis usually comes to a standstill, although cases have been recorded in which later reinfections occurred from this source.

Diffuse glandular tuberculosis in such cases is beyond the reach of safe surgery. Caseous glands in the mesentery, corresponding with the portion of the intestine excised, should be removed by including the mesentery in the excision. So far excision has

only been performed in cases in which the tubercular lesion gave rise to intestinal obstruction. The results of this operation will be greatly improved in the future when intestinal resection will be performed as soon as a localized tubercular lesion can be diagnosticated, and before the patient's general condition has been seriously impaired by the mechanical obstruction.

Intestinal resection has been most frequently performed for tuberculosis in the ileo-cecal region. A number of cases, however, have been recorded in which the seat of the disease was the small intestine. Dr. Rudolph Matas made a successful enterectomy for intestinal stricture, following the healing of a tubercular ulcer involving the upper portion of the jejunum. The patient made a rapid and permanent recovery. (Personal communication.)

König ("Die stricturirende Tuberculose des Darmes und ihre Behandlung," *Deutsche Zeitschrift f. Chirurgie*, 1892, B. xxxiv, p. 62) reports five cases of stricture of the intestine caused by cicatricial contraction of tubercular ulceration, all treated by laparotomy and resection of the intestine with circular enterorrhaphy. Two of the patients died; one from exhaustion, the other from the giving way of a suture, an accident which resulted in leakage and diffuse peritonitis. He believes that this pathologic form of cicatricial stenosis is much more frequent and more easily recognized than has hitherto been thought. He has met with this affection most frequently in persons between 20 and 30 years of age, and especially in those suffering from other tubercular lesions. He has made a careful investigation of such cases and found that the clinical history usually reveals a chronic cause, frequent attacks of colic with constipation, tympanites, visible peristalsis and peculiar splashing and musical sounds, ending with a sound which resembles that of fluid driven forcibly from a syringe. The disease invariably produces great emaciation and anemia. In spite of the feebleness of the patients, König thinks surgical interference advisable, especially as the ulceration is probably still progressing in part of the cicatricial contraction and often the tubercular disease elsewhere is not far advanced.

Treves ("Resection of Intestine," *The Lancet*, Jan. 4, 1896) made a resection of the intestine for tubercular stricture and united the bowel ends by the use of Murphy's button. The patient made a satisfactory recovery.

Sachs (*Archiv für klin. Chirurgie*, 1892, B. 43), reports the following case of resection for intestinal tuberculosis: A woman, aged 41, had suffered for a long time from constipation, and for two years had had loss of appetite and gradually increasing marasmus and debility. On examination a hydronephrosis of the right kidney was discovered, and also a swelling in the right iliac fossa, which was supposed to be of a malignant nature. Laparotomy was performed when the right iliac fossa was found to be filled up by a hard swelling, which was the size of an adult's fist. Surrounding the ileum was a band of contracted fibrous tissue with tubercular granulations in some places. The diseased parts were resected and the two ends of the intestine joined together by circular enterorrhaphy. The patient recovered and was in a satisfactory condition several weeks after the operation. On examination of the specimen removed the ileum was seen to be surrounded by a band of scar tissue and granulations. At the junction of the ileum with the cecum there was a large tubercular mass, which extended to

the mesenteric glands. The mucous membrane of the cecum was replaced by tubercular granulations, which extended into the muscular coat, and on microscopic examination were seen to consist of epithelioid and giant cells. He collected thirteen cases of resection of the ileo-cecal portion of the intestinal canal for tuberculosis, of which eleven recovered.

Zahlmann (*Hospitals Tidende* 1892, No. 36) reports a case of tubercular stricture of the intestines removed by Tage Hansen of Denmark. The patient, a girl, aged 17 years, had been previously treated for tuberculosis of the phalanges of the fingers and toes. For one and a half years she had exhibited signs of stricture of the intestines, and at the laparotomy the entire cecum, with the adjacent parts of the ascending colon and ileum, was found to be the seat of an inflammatory mass which had produced a stricture an inch and a half in length, of a diameter corresponding to that of a lead pencil, while the walls were nearly an inch in thickness. Six inches of the ileum, the entire cecum and four inches of the ascending colon were removed. The healthy ends of the ileum and colon were united by means of Lembert's sutures, the difficulty in adapting the different lumina to each other being overcome by dividing the ileum by an oblique section at the expense of the convex side. The patient recovered and remained in good health at the time the report was made six months after the operation.

Of five cases of intestinal tuberculosis in which the cecum and colon were the seat of disease, and in which Czerny resorted to resection and circular suturing, two died of peritonitis and one of hemoptysis after complete recovery from the operation. In one case the peritonitis was caused by leakage through one of the needle punctures, and in the second the perforation occurred in consequence of abscess formation in the line of suturing. The patient died from the effects of peritonitis, septic pyemia and metastasis, five weeks after the operation. In one case the operation proved successful, but was followed by rapid generalization of the tubercular process, an observation fully corroborated by Wahlländer and Wolff, who have called special attention to the diffusion of tubercular processes after intervention for what appeared as localized processes. In one case of secondary tuberculosis, following rupture of a tubercular adnexal abscess into the intestine, circular suturing after excision was found impossible and consequently an artificial anus was established with an excellent functional result. Among the cases operated upon by Czerny, and reported by Rindfleisch ("Ueber die an der Heidelberger Chir. Klinik ausgeführten Operation am Magen und Darne." *Beiträge zur Klin. Chirurgie* B. ix, p. 661), are several in which the remote results of operations for intestinal tuberculosis have since been ascertained. In the case of a woman, 34 years of age, operated upon in 1886, nothing definite could be learned as to the subsequent history. In the case of an ileocecal resection performed in 1888, on a man 30 years of age, death resulted three years later from pulmonary tuberculosis. The postmortem revealed tubercular ulcers in the colon and small intestines, with miliary tubercles on the peritoneal surface and cheesy mesenteric glands. No information could be had in the case of a man, 54 years of age, subjected to ileo-cecal resection, but the operation appeared to have exerted no influence in checking the progress of the pulmonary affection. A man, 26 years old, died of pulmonary tuberculosis two years after the operation. A woman,

22 years of age, was in good health four years after the operation. A man, 31 years old, was found in excellent health four years after the operation, having gained during this time twenty-three pounds in weight. This patient suffered only occasionally from catarrh of the colon, the attacks being of short duration. These cases go to prove that resection for intestinal tuberculosis in well selected cases yields satisfactory remote results, while the reverse is true if the operation is performed under adverse conditions.

Rentier ("Cæcum provenant d'une résection iléo-sacrée pour tuberculose." *Bulletins et Mémoires de la Société de Chirurgie*, 1896, No. 7) resected the entire cecum for tuberculosis and united the bowel ends by means of Murphy's button. Death occurred on the sixth day after the operation. The lumen of the button, which remained *in situ*, was completely blocked by feces. Additional tubercular ulcers were found in the jejunum.

Caminiti-Vinci (*Riforma Medicina*, July 11, 1896) reports the case of a man, aged 24, without any tubercular family history, who for the last nine months had suffered from severe pain in the left superior quadrant of the abdomen, aggravated after meals; no diarrhea or vomiting. In the affected region an ill defined swelling could be felt, descending slightly with inspiration, rather painful on palpation. The patient, not improving under medical treatment, was operated upon March 8, 1896. The omentum was found thickened, hard and adherent to the small intestine for about ten centimeters; this was excised, and also about thirty centimeters of the intestine itself, with its mesentery and glands. The bowel was united by circular suturing. The patient recovered and remained in good health four months after the operation. Macroscopic and microscopic examination proved the tubercular nature of the disease in the parts removed.

Courtillier ("Tuberculose chronique de l'angle ileo-cæcal. Resection, Enterorrhaphie, Guérison, Fistule pyo-stercorale, Operation, Mort, Autopsie." *Bulletin de la Société Anatomique de Paris*, 1896, No. 13) reports the case of a boy, 12 years old, operated upon by Broca for tuberculosis of the cecum. The entire cecum was resected and the ileum united with the ascending colon by circular suturing. The patient recovered from the operation and remained in perfect health for three years, when a fecal fistula appeared at the site of operation. Operation for closure of the fistula was followed by death. The autopsy showed the small intestine in a perfectly healthy condition, but the disease had reached the ascending colon and was complicated by tuberculosis of the left lung.

Durante ("Resezioni intestinali per tubercolosi del cieco." *R. Acad. Medica di Roma*, No. 4, 1895) has resected the cecum for tuberculosis five times. He calls attention to the difficulties presented relative to making an early diagnosis. Intermittent diarrhea for two to six years is a conspicuous and almost constant symptom. For a long time the general health is not much impaired. Symptoms of progressive cicatricial stenosis finally appear. In one case he was able to ascertain from examination of the specimen that the tubercular process had its primary starting point in the appendix. Of the five cases four lived and were in good health five to seven years after the operation. In one case relapse was due to incomplete removal of the infected tissues. He regards the prognosis as favorable after a complete extirpation of the affected portion of the intestine.

Emil Müller ("Extra-abdominal Tarmresection mid fortsatz; Extra-abdominal Behandling, *Hospitals Tidende* No. 3, 1896) resorted to resection in two cases of tubercular stricture of the intestine. In the first case the disease extended over the lower part of the ileum, cecum and ascending colon to within an inch of the right colic flexure. In the second case, the operation was performed extra-peritoneally. After opening the abdomen by lateral incision the colon was made movable by incising the external layer of the meso-colon, when the diseased portion of the intestine was brought forward into the wound. The inner layer of the meso-colon was sutured to the inner margin of the incision and the peritoneal cavity on the outer side of the bowel was shut out with an iodoform gauze tampon. After six days the affected portion of the intestine was extirpated extra-peritoneally. The continuity of the intestinal canal was restored by circular suturing, which could be done without invading the excluded peritoneal cavity. The external wound was sutured and drained. The patient recovered rapidly, without any untoward symptoms and was discharged from the hospital with his health restored.

To what extent operative procedure can be carried in true cases of intestinal tuberculosis with ultimate recovery is well shown by a case reported by Körte (*Verhandlungen der Deutschen Gesellschaft für Chirurgie*, 1894.) The patient, a man, 25 years old, was operated upon in 1891 for acute suppurative peritonitis. The following year, March 16, the appendix was removed. In August, of the same year, a swelling developed along the course of the cecum and ascending colon. August 27, the cecum and ascending colon, nearly as far as the hepatic flexure, were excised. Healthy tissue was not reached. An artificial anus was established. The microscope demonstrated the tubercular nature of the intestinal affection. The enterotome was used without any benefit. In November, twenty-one centimeters of the colon was resected. The end of the colon was invaginated and sutured and an entero-anastomosis established between the colon and the lower portion of the ileum. A fecal fistula followed the operation. In February, 1893, Diffenbach's enteroplasty was performed, but proved unsuccessful. In May, a loop of the small intestine was implanted into the sigmoid flexure. For two weeks there were normal evacuations per rectum, then a fecal fistula formed. July 3, what was left of the colon was permanently and completely excluded by closing both ends. Regular evacuations by rectum followed. July 23, the excluded colon was resected. Patient recovered. Subsequent treatment was with iodoform gauze packing. The fecal discharge from the fistula was always liquid, but as soon as it passed through what remained of the colon the stools became natural. Only one case of resection for intestinal tuberculosis has come under my own observation.

Tuberculosis of the cecum and ileum; resection of cecum and eighteen inches of the ileum with corresponding portion of mesentery. Restoration of continuity of intestinal canal by lateral anastomosis with the aid of decalcified bone plates. Recovery; return of the intestinal affection and death six months after operation.—The patient was a spare man of medium height, 37 years of age, and a farmer by occupation. He is unaware of the existence of any hereditary taint or predisposition to tuberculosis or malignant disease in the family. His health was excellent prior to Aug. 16, 1887. On that day he was taken suddenly ill with an attack of vomiting, without any obvious cause, which lasted for six hours. The patient insists that toward the last he vomited fecal matter. He recovered rapidly and remained in comparatively good health until

the following October, when he suffered from a similar attack of four hours duration. This time he experienced a sharp pain in the ileo-cecal region, and soon after felt a distinct swelling in that locality. From this time on until March, 1889, the pain recurred periodically, the intervals becoming shorter until pain became almost continuous with few and incomplete remissions. During this time he suffered also a great deal from flatulence. The bowels were inclined to be loose, but the general health was not seriously impaired. Since March, 1889, diarrhea became a prominent symptom, the stools being liquid, but showing no trace of blood or mucus. Pain increasing in severity and more constant, and always partially relieved by the free escape of gas per rectum. At the time he entered the hospital (Oct. 9, 1889), he had lost forty-five pounds in weight. Examination at this time revealed the existence of a hard, nodulated, fixed swelling in the ileo-cecal region, and tympanites in the hypogastric and umbilical regions. Distention of the colon by rectal insufflation of hydrogen gas made the swelling more prominent and defined. Not much tenderness on pressure. Digital exploration of the rectum yielded a negative result. Marasmus and anemia were well marked. For the last seven months the patient has had daily from four to six liquid discharges from the bowels. Appetite is impaired, slight rise in the evening temperature, pulse from 80 to 90 per minute. From the history of the case, and more especially from the character and location of the swelling, a probable diagnosis of tuberculosis of the cecum was made. As the usual medical treatment, which had been pursued for months, afforded but temporary relief, the consent of the patient and his friends to an operation was readily obtained. Laparotomy was performed on the day of his admission into the hospital. The abdomen was opened by an incision from near the middle of Poupart's ligament to a point half way between the anterior superior spinous process of the ileum and umbilicus. On opening the abdomen the swelling at once came within easy reach. Examination showed that the swelling involved the entire circumference of the cecum, and its immobility suggested that it was intimately connected with the retroperitoneal tissues by inflammatory adhesions. The lower portions of the ileum and cecum were emptied by displacing their contents, and each part was entrusted to an assistant, who was instructed to prevent fecal extravasation by digital compression, until the completion of the anastomosis. The ascending colon was divided about two inches below the margin of the swelling and the ileum near its junction with the cecum; both sections showed that the visceral incisions had been made through healthy tissue. The bleeding vessels were tied with fine silk ligatures. Several large partially caseous glands were found in the retroperitoneal space behind the cecum and enucleated in one large mass with the cecum and a portion of peritoneum, which was adherent to the glands. After the removal of the cecum it was noticed that the mesentery of the lower portion of the ileum contained several enlarged glands, consequently, after preliminary ligation, it was excised with eighteen inches of the ileum. During the whole operation a small compress was kept in the abdominal cavity to prevent prolapse of the small intestines, and to guard against infection. After all hemorrhage had been carefully arrested, both ends of the bowel were closed by invagination and a few stitches of the continuous suture; the first stitch was made to transfix the mesentery at the point where it was invaginated into the bowel. Medium sized perforated decalcified bone-plates were used in making the ileo-colostomy, by lateral approximations. An incision about two inches in length near the closed ends of both intestines was made at a point opposite the mesenteric attachment, and into each opening a bone plate was inserted, and the lateral sutures, armed with a needle, were passed about an eighth of an inch from the margin of the visceral wound, from within outward and in such a way as not to include the peritoneum, at a point half way between the angles of the wound. The surfaces of the bowel corresponding to the part covering the plates were freely scarified with an ordinary sewing needle. The visceral wounds were now brought *vis à vis* in such a manner that both closed ends were directed downward, bringing in this way the free surface of the colon and ileum together. Before any of the plate sutures were tied, a number of Lembert sutures were applied posteriorly, so as to approximate the serous surfaces along the margin of the plates, thus affording additional security in maintaining coaptation. The posterior pair of approximation sutures was now tied with sufficient firmness to hold the parts in contact without sufficient pressure to cause gangrene, after which both pairs of sutures not armed with needles were tied. During the tying of these sutures it is of the greatest importance that an assistant should keep the plates accurately and closely pressed together. The last to tie was the second anterior pair of trans-

fixion sutures, and as this was being done the bowel on each side was carefully pushed in between the plates with a probe. After all the approximation sutures were tied, it only remained to apply on the anterior side a few Lembert sutures. After the exposed parts were disinfected and dried, the bowel was returned into the abdominal cavity and anchored near the wound with a silk suture, which was made to embrace the parietal peritoneum on one side and the mesentery on the other, at a point opposite the anastomotic opening. The abdominal incision was sutured throughout, no provision was made for drainage. The subsequent history of the case was uneventful. The highest temperature registered was on the third day when it reached 101.5 degrees F., but returned to normal on the fourth day. During the first two days liquid food was administered by rectum. After that time the patient was allowed milk, beef tea and raw eggs, and after another week he was given the ordinary hospital diet, which he relished. The bowels moved several times a day, the passages gradually becoming normal in color and consistence. The external wound healed by primary intention with the exception of a small place where a stitch abscess formed at the end of the first week. At the ninth day half of the plate in the colon passed per rectum, and the following day the remaining half, with the plate from the ileum with the sutures attached, were found in one of the stools. The patient left his bed on the twenty-eighth day after the operation, and three days later he returned to his home. At the time he left the hospital nothing abnormal could be felt in the right iliac fossa, no pain and no tenderness on pressure. He gained rapidly in flesh and strength, and when I saw him again, during the latter part of January, 1890, he weighed nearly as much as before he was taken ill. Since the operation he has had no pain, no diarrhea, and the discharges from the bowels once or twice a day were normal in every respect. At this time, however, I was able to detect a small hard swelling behind the colon at a point above where the ileum had been attached, which I regarded as a recurrence of the disease along the chain of lymphatics behind the peritoneum, but no evidence of a return of the disease in the bowel could be found. In the course of a few months the patient died from the effects of the recurrent disease without any symptoms of obstruction.

I have had reason to regret that I did not resort to a second operation as repeated operations in similar cases have finally succeeded in eliminating the disease. The specimen removed represents the entire cecum, a number of cheesy mesenteric and retroperitoneal glands, eighteen inches of the ileum with the corresponding mesentery. A few small tubercular ulcers were found in the lower portion of the section of the ileum removed. The tubercular process had evidently started in the cecum which it involved in its entire circumference. The walls of the cecum had become greatly thickened by the infiltrations. The lumen of the ileo-cecal valve was not larger than an ordinary lead pencil, and the interior of the cecum, near the valve, presented a number of deep excavations resulting from the breaking down and ulceration of the tubercular mass. The ileum for a considerable distance was the seat of a well marked compensatory hypertrophy, the thickening of its walls being due to an increase in muscular fibers, a result which so constantly follows progressive intestinal stenosis. The presence of numerous caseous mesenteric and retroperitoneal lymphatic glands, the character of the ulcers and microscopic examination of the diseased tissues removed, proved the tubercular nature of the inflammatory process. Although in this and some other cases the use of decalcified bone plates proved satisfactory in establishing a lateral anastomosis, I have discarded largely this and similar mechanical aids in intestinal surgery and have learned to rely on suturing in all cases in which there are no contraindications presented to this method of dealing with intestinal wounds.

From the accumulated experience of the past in the treatment of intestinal tuberculosis by resection, it becomes evident that this operation is indicated in all

cases in which the disease is sufficiently circumscribed to admit of complete removal, and the general condition of the patient is such as to entitle us to the hope that the operation will not prove fatal by its immediate effects. It is in such well selected cases that enterectomy will find far better results than any other operative procedure, as it has for its object the complete eradication of the disease, thus protecting the patient against reinfection from this source.

Partial physiologic exclusion of affected portion of intestinal canal by entero-anastomosis.—Ten years ago I made a series of experiments on the lower animals for the purpose of demonstrating the value of partial physiologic exclusion of the intestine by entero-anastomosis in the treatment of certain localized affections not amenable to resection. The results of the experiments proved that the excluded portion undergoes atrophy and is placed in a condition approaching physiologic rest. In none of the experiments did the excluded portion become the seat of fecal accumulation.

In the introduction to this part of the paper on "Experimental Intestinal Surgery," I said: "As extensive resections of the intestine are always attended by great risks to life from trauma, I concluded to study the subject of sudden deprivation of the system of a more or less extensive surface for digestion and absorption, by eliminating or diminishing the cause of death from this source, by leaving the intestine, but by excluding permanently a certain portion from participating in the functions of digestion and absorption: in other words, by resorting to physiologic exclusion. These experiments were also made to determine the tissue changes which would take place in the bowel thus excluded, and to learn if under such circumstances accumulation of intestinal contents would take place and constitute a source of danger, as had been feared by the older surgeons."

The results of the experiments, as well as clinical experience since that time, have shown conclusively that this fear is unfounded. In speaking of the results of the experimental work and its application in intestinal surgery, the following statements were made in the same paper: "The exclusion was complete, or nearly so, hence we must conclude from the postmortem appearances, that in nearly every instance the excluded portion presented an absorptive, contracted condition, and was only sparingly supplied with blood vessels. From a practical standpoint these experiments teach us that a limited portion of the intestinal canal can be permanently excluded from the processes of digestion and absorption in proper cases, by operative measures without incurring any risk of fecal accumulation in the excluded part. These experiments demonstrate also that physiologic exclusion of a certain portion of the intestinal tract is a less dangerous operation than excision, and that in certain cases of intestinal obstruction where excision has heretofore been practiced, it can be resorted to as a substitute for this operation in cases where excision is impracticable or where the pathologic conditions which have caused the obstruction do not, in themselves, constitute an intrinsic source of immediate or remote danger to life. The postmortem appearances of the specimens of these experiments tend to prove that as long as any of the contents of the intestines reach the excluded portion, the peristaltic or antiperistaltic action in that part is effective in forcing it back into the active current of the fecal circulation."

Since that time entero-anastomosis has become a well established operation, and has proved of signal success in the treatment of limited intestinal tuberculosis complicated, as it so often is, by cicatricial stenosis. The operation effects two desirable objects in the treatment of such cases. 1, it relieves the symptoms of intestinal obstruction; 2, it secures rest for the part affected. I have had an opportunity to perform entero-anastomosis in two cases of intestinal tuberculosis.

Intestinal tuberculosis complicated by acute intestinal obstruction caused by cicatricial stenosis; ileo-ileostomy; recovery; patient in almost perfect health two years after the operation.—The patient was a boy 16 years of age, member of a healthy family, free from any predisposition to tuberculosis or malignant disease. He had never been seriously ill and was in the best of health, weight 140 pounds when he was attacked with colicky pain, which he referred to the umbilical region, December, 1895, which continued for two days. He recovered from this attack and remained in fair health until Dec. 18, 1896, when he was again seized with fever pains in the abdomen of a colicky nature, which continued until he entered the hospital. Bowels had not moved for two days prior to his present illness. Vomiting which soon became fecal, and absolute constipation followed by great tympanites came on in rapid succession. The attending physician made a diagnosis of intestinal obstruction and resorted to the usual treatment including the use of high rectal enemata with little or no relief. When he was admitted into the St. Joseph's Hospital, March 1, 1896, he had lost forty pounds in weight. He was very anemic and the emaciation was pronounced. The abdomen was enormously distended, visible intestinal coils could be distinctly outlined. Temperature was normal, pulse small, 100 per minute. There had been no free movements from the bowels since the attack; frequent attacks of vomiting, at times fecal in character. Rectal examination yielded no information regarding the anatomic location or nature of the obstruction. The day after his admission into the hospital, after thorough preparatory treatment, laparotomy was performed. The abdomen was opened in the median line, half way between the umbilicus and pubes. Intestinal coils, enormously distended and exceedingly vascular, protruded at once from the wound and were carefully protected with compress wrung out of a hot physiologic solution of salt. One of the first things noticed was the existence of numerous enlarged mesenteric glands. Some of them were the size of a hazel nut and presented distinct evidences of beginning caseation. The visceral as well as the parietal peritoneum was studded with innumerable tubercle nodules. The existence of peritoneal and glandular tuberculosis was at once made evident. In searching for the seat of the obstruction the distended intestine was traced in a downward direction, the intestinal loops being replaced as soon as examined so as to prevent extensive eveneration. In reaching the lower part of the ileum, the obstruction was found about twelve inches above the ileo-cecal junction, in the form of a tight circular stricture. Above this point the intestine was uniformly distended, very vascular, while below the obstruction the intestine was empty, contracted and pale. An ileo-ileostomy was made by establishing an anastomotic opening between the lower part of the distended ileum and that part of the ileum between the obstruction and the cecum. Before the visceral incisions were made the serous surfaces of the convex side of the intestinal loops, which were to be united, were sutured together with a row of Lembert stitches, extending a little beyond the intended limits of the incisions. On incising the proximal, distended loop the bowel was drawn well forward, the patient placed on his right side and as much of the intestinal contents as could be poured out was evacuated through the incision. After incising the empty loop to the same extent the mucous membrane was sutured all around and finally a row of anterior serous stitches completed the operation. The parts exposed were thoroughly cleaned, dried and lightly dusted with iodoform, after which the intestines were returned and the external incision closed in the usual manner. The patient recovered promptly from the immediate effects of the operation. The incision healed by primary intention throughout. The bowels moved freely the day after the operation. The tympanites diminished rapidly and disappeared entirely in the course of a week. For a few days the stools were copious and liquid, later once a day and normal in color and consistence. Rectal feeding was continued for four days, later liquid food by the stomach, followed by solid food at the end of the first week. The patient left the hospital in

excellent condition, March 30, 1896. A letter from his physician received recently, states that he is in perfect health, having gained twenty-seven pounds in weight two years after the operation.

Careful search for tuberculosis in other organs was made but proved negative. The tubercular nature of the intestinal affection in this case was obvious from the simultaneous existence of peritoneal and lymphatic tuberculosis. The entero-anastomosis relieved the obstruction promptly and placed the affected organs in a condition for spontaneous healing of the tubercular lesions. The patient was placed upon the prolonged internal use of guaiacol, which may have contributed to the remarkable result of the operation.

Tuberculosis of the cecum and ascending colon, complicated by tuberculosis of the urinary organs; ileo-sigmoidostomy; death forty-eight hours after operation from exhaustion.—The patient was a man 38 years old, who was admitted into the Presbyterian Hospital Nov. 6, 1897. His health began to decline four years ago, when symptoms of chronic cystitis developed. For a long time the urine contained pus and at times blood. In February, 1896, he had a chill followed by fever and pain in the region of the right kidney. A swelling developed below the costal arch on the same side and soon reached as far as the crest of the ilium, and to within an inch or two of the median line on the left. The temperature ranged between 102 and 104 F. for five days. A second chill occurred a few days later followed by slight jaundice, which continued for a few days. The swelling was diagnosed as an abscess, which was incised in front at a point half way between the last rib and crest of the ilium. On cutting through the abdominal wall the distended kidney presented itself and was incised, and about a pint of pus escaped. The cavity was washed out and drained. For some time urine escaped through the drainage opening. Three weeks after the operation feces escaped through the opening and the fecal fistula has remained since that time. At the time the patient entered the hospital he was very anemic and greatly emaciated. Examination of the bladder and prostate left no doubt that both of these organs were the seat of a tubercular affection. Through the fistulous opening a probe could be inserted into the ascending colon. Gas and fecal material escaped through the opening daily. Action of bowels irregular, diarrhea and constipation alternated with each other. From the cecum in the course of the colon a resistant swelling could be felt, which extended somewhat above the fistulous opening. Examination of the lungs revealed a limited infiltration in the left apex. A slight rise in the evening temperature was almost a constant feature. The fistulous opening externally was enlarged and a large cavity found between the skin and abdominal muscles, which was lined with fungous granulations. These were scraped out with a sharp spoon and the cavity thoroughly disinfected and packed with iodoform gauze. This and the subsequent operations were performed in the clinic of Rush Medical College. The scraping out of the cavity was followed by increased fecal discharge and in a short time the fistulous opening in the colon was large enough to insert the tips of two fingers. Carbonate of guaiacol and tonics were administered internally, but the patient continued to lose strength and flesh. Owing to the existence of formidable complications and the extent of the intestinal affection I decided to exclude the cecum and colon, as far as the sigmoid flexure, from the fecal circulation, by performing ileo-sigmoidostomy.

After making careful preparation the operation was performed Dec. 20, 1897. The abdomen was opened in the median line. The cecum and ascending colon, nearly as far as the hepatic flexure, were found imbedded in an extensive exudate. Numerous enlarged lymphatic glands especially in the meso-cecum and mesentery of the ascending colon. The anastomotic opening was established between the ileum, about eighteen inches above the cecum and the sigmoid flexure. The operation was performed in a similar manner as in the case of lateral anastomosis after excision with the exception that no bone plates were used, the visceral wounds being united by two rows of sutures. The operation was completed in less than an hour. Very little shock followed. The next day, however, vomiting and symptoms of prostration set in, the pulse became more rapid and feeble, but the temperature never exceeded 100 F. Death occurred forty-nine hours after the operation.

The clinical history in this case points to primary tuberculosis of the urinary organs followed by intestinal and, later, pulmonary tuberculosis. A number

of cases have been reported in which entero-anastomosis was performed for intestinal tuberculosis. Hofmeister ("On Multiple Stenosis of the Intestine of Tubercular Origin," *Beiträge zur Klinischen Chirurgie*, B. xvii, No. 3) reports a case of multiple tubercular strictures of the intestine treated by establishing an entero-anastomosis. The patient, a man aged 32, had suffered for four years with attacks of colic accompanied by vomiting and constipation, recurring at intervals of greater or less length, the last seizures had been particularly severe. Finally the patient was taken to the surgical clinic of Bruns, at Tübingen, with all the symptoms of a marked intestinal obstruction. The operation, which was undertaken without delay, revealed ten annular strictures of the small intestine, for the most part, very narrow and distributed over two meters of the bowel. The large intestine was absolutely empty and contracted. Resection being out of the question on account of the debilitated general condition of the patient an anastomosis was made between the intestines above and below the seat of obstruction. At the very outset the distended intestine was punctured with a small trocar, to evacuate its contents. The puncture was closed with two rows of sutures. The patient was temporarily improved by the operation, but died the following day in sudden collapse. The autopsy revealed the fact that death had been caused by a general peritonitis. Inspection showed that the sutures inserted for the purpose of closing the puncture-opening were insufficient to resist the intra-intestinal pressure by gas, and had given way, followed by fecal extravasation. Besides the ten discovered at the operation, two additional strictures were found, one near the ileo-cecal valve and the other a little higher up. When the strictures are multiple the disease usually involves the ileum. Hofmeister found records of eighteen cases of multiple strictures of the intestines of a tubercular nature.

Murwedel ("Ueber Entero-anastomosis," etc. *Beiträge zur Chirurgie*, B. xiii, Heft 3) reports a case of tuberculosis of the cecum treated by entero-anastomosis from Czerny's clinic. The patient was a man, 43 years of age. No hereditary predisposition to tuberculosis in the family. He suffered from two attacks of localized peritonitis, probably caused by appendicitis, the first in 1870, the second in 1887. Since last attack pain and tenderness in the right iliac fossa remained. In 1891, the pain increased, attended by colicky pains in the abdomen, the latter disappeared after two or three minutes under a loud pouring sound. Bowel movements were irregular. A few weeks before his admittance into the clinic eructations and transient vomiting returned. He was treated for some time in the medical clinic, by high enemata without any benefit. He was admitted into the surgical clinic, August 17, 1893. At this time with the exception of a chronic conjunctivitis, rhinitis and pharyngitis and a slight pulmonary emphysema, the general health of the patient did not appear to be much impaired. Cecal region was prominent, and to the right of the cecum and ascending colon, particularly the latter, a hard cylindrical swelling could be felt, extending from the iliac spine to the tip of the eleventh rib. The swelling was fixed and tender on pressure, there was visible peristalsis of small intestines near cecum.

Clinical diagnosis: Stenosis and tumor formation in the region of the cecum and ascending colon, chronic

inflammatory (perhaps tubercular) process. First operation, Aug. 20, 1893. Vertical incision in the linea Spigellii showed infiltration of pre-peritoneal tissues and firm adhesions between anterior abdominal wall and ascending colon. In separating the adhesions an ulcerated portion of the colon near its middle was torn and a quantity of pus but no fecal material escaped. From this opening digital exploration showed that the colon was ulcerated as far as the ileo-cecal valve, which induced the operator to abandon all thoughts of performing a resection. The tear in the bowel was sutured and an entero-anastomosis made. The lower portion of the ileum was distended and hypertrophied, on the other hand the transverse colon contracted and atrophied. These two parts of the intestinal canal were then brought into communication by establishing, by incision and suturing a free anastomotic opening. The sutured wound of the colon was fastened to the abdominal wall with two peritoneal sutures. External incision was closed with the exception of a space over the cecum to secure drainage, which was effected by using the iodoform gauze tampon. The diagnosis made at this time confirmed the previous suspicion of the tubercular nature of the affections. Bowels moved on the second day after the use of an enema. A week after the operation some fecal matter was mixed with the discharge from the wound. When the patient was discharged, four weeks after the operation, the wound was healed, with the exception of a fistula, which discharged a small quantity of pus, but no fecal material. Bowels moved without the aid of cathartics or enemata. General conditions much improved. During the fall of the same year, he was attacked with influenza and at the termination of the illness the parts around the fistula became inflamed and soon after, a more copious flow of pus ensued, which became mixed with feces. He re-entered the clinic Nov. 31, 1893. The swelling in the cecal region was smaller but firmer than at the time of operation. There was constipation, which when relieved by cathartics, was followed by diarrhea, some of the fecal material escaping through the fistula. At this time the fistulous tract was enlarged with the knife sufficiently to enable exploration of the abscess cavity with the finger. The cavity was about the size of a walnut, partly filled with hard fecal masses and lined with tubercular granulations. Curettage and iodoform gauze tamponade were used. After operation nearly all of the feces escaped through the fistula. Third operation was performed December 7 of the same year. The old scar was incised and the adherent ascending colon separated. During this step of the operation a small subcutaneous abscess was opened. The fistulous opening was next exposed and was found near the lower end of the ascending colon, where a defect was found large enough to admit the tip of the index finger. Exploration of the interior of the cecum revealed a large cicatrized surface. The margins of the intestinal fistula were vivified and the opening closed with two rows of sutures, the operation being entirely extra-peritoneal. The external incision was closed with the exception of a space large enough to bring out the iodoform gauze tampon. No unfavorable symptoms followed the operation. Normal stool after injection on the eighth day. Patient left the hospital with a small fistula on the last day of the same month, almost in perfect health and with normal bowel movements. One year later the fistula still remained

and at times small quantities of feces escaped, otherwise the patient was in good health and had gained twenty-three pounds in weight. Czerny attributes the healing of the extensive tubercular ulcerations to the elimination of the affected part of the bowel from the fecal circulation by the ileo-colostomy. Schiller reports three cases of intestinal tuberculosis treated by physiologic exclusion of the affected part, operated upon in Czerny's clinic during a period of four years. ("Ueber Darmoperationen an der Heidelberger Chirurgischen Klinik, etc." Dissertation, 1896.) In all cases the disease was located in the cecum and had given rise to chronic obstruction. In two cases the anastomotic opening was made between the ileum and transverse colon, and one between the ileum and the ascending colon. In two cases the cecum was incised and the tubercular ulcers curetted. The visceral incision was closed by suturing parallel with the long axis of the bowel. In one case the diseased appendix was excised in addition. In one the gall bladder was extirpated at the same time for lithiasis and chronic inflammation. In all of the cases the contraindications to resection were well defined. In one case the operation was done by the use of the Murphy button, which was removed from the ampulla of the rectum on the fifteenth day after a severe hemorrhage three days previously. The pulmonary symptoms became seriously aggravated after the hemorrhage. All these cases recovered and the patients left the hospital improved. In one case (reported *in extenso* above), a fecal fistula developed, which was sutured on two occasions with partial success.

The exclusion of the affected part of the intestine although not complete, led to speedy healing of the ulceration, as was shown in one case at the second operation, four and one-half months later. The healing of the ulcers was undoubtedly favored by the atrophy and diminished peristaltic action, conditions which are always established in the excluded part soon after the operation.

James Israel ("Ueber Chirurgische Heilung von Peritoneal und Darmtuberkulose," *Centralblatt für Chirurgie*, 1896, No. 4) reported to the Surgical Society of Berlin a case of tuberculosis of the cecum and ascending colon in a woman 20 years of age, greatly improved by establishing a communication between the ileum and the ascending colon. The disease was attended by symptoms indicative of chronic intestinal tuberculosis. Exploratory laparotomy was performed and a probable diagnosis of sarcoma was made. The mesenteric glands were found enlarged. Later a second operation was performed, when a swelling the size of an apple was found projecting into the ascending colon, complicated by disseminated peritoneal tuberclosis. The patient made a good recovery, gained in weight, and after seven months, the swelling was reduced in size to that of a walnut.

Gessner ("Entero-anastomose bei tuberculöser Darmstriktur," *Centralblatt f. Chirurgie*, 1896, No. 6) made a laparotomy on a case in which the cecum was tubercular and had attained the size of a goose-egg. The swelling was nodulated and the serous coat studded with miliary tubercles. The obstruction caused by cicatricial stricture in the region of the ileo-cecal valve was relieved by an anastomosis between the ileum and the ascending colon, which was made by the aid of the Murphy button. The button was discharged per rectum on the thirteenth day.

The operation was followed by manifest improvement.

A very interesting case of intestinal tuberculosis complicated by invagination came under the observation of Czerny and is reported in detail by Murwedel ("Ueber Entero-anastomose, etc." *Beiträge zur Klinischen Chirurgie*, B. xiii, Heft 3). The patient was a boy 14 years of age who, two months prior to his admission into Czerny's clinic, was suddenly taken ill with vomiting and severe pain in the abdomen, attended with the appearance of a swelling in the upper and right side of the abdomen. In a few days the pain subsided and the vomiting occurred less frequently. A sausage-shaped tender swelling, above the umbilicus, remained. Bowels could only be moved by the use of injections. For a few days during the early part of the attack the stools contained traces of blood. On his admission into the clinic, June 2, 1894, the patient presented an anemic appearance and was considerably emaciated. There was no fever, lungs and heart normal. Inspection and palpation revealed the existence of a cylindric swelling, ten centimeters in length, in the region of the transverse colon. The swelling was slightly movable and tender on deep pressure. Liver, spleen and kidneys were normal in size and function. Under rectal insufflation the swelling increased in size, and dulness on percussion gave way to tympanitic resonance. Capacity of colon was only three pints. The rectal injection did not increase the dulness on percussion over the swelling and was followed by the escape of hard fecal masses. Chronic invagination of ascending and transverse colon was diagnosed. Operation was performed June 6. Median incision was made from xiphoid cartilage to umbilicus, which later had to be extended two inches to bring the invaginated colon forward into the wound. The swelling, the size of two fists, was composed of the cecum and ascending colon, into which the lower portion of the ileum had become invaginated. The intussusception could be traced as far as the right flexure of the colon. Reduction, owing to the presence of extensive adhesions, was found impossible, and resection was contraindicated by the debilitated condition of the patient. An entero-anastomosis between the ileum above the invagination and the middle third of the transverse colon, was established by incising the previously approximated ileum and colon and suturing the visceral wounds with two rows of sutures in the usual manner. Abdominal incision was closed throughout.

The existence of a tubercular lesion of the invaginated bowel was suspected from the presence of a plastic caseous perityphlitis. Recovery was without any untoward symptoms. Patient left the hospital August 9, swelling much diminished in size, bowel movements normal. A year later the patient remained in good health and examination showed that the invagination had nearly disappeared. The tubercular complication presented itself in the form of caseous adhesions found at the time the operation was performed. The infection probably occurred from the intestinal canal. Whether the tuberculosis occurred as a primary affection or whether it appeared after the invagination had taken place, would be difficult to determine. Flenier describes two other cases of intestinal tuberculosis from Czerny's clinic in which the pathologic conditions produced by the disease gave rise to invagination (*Virchow's Archiv*, B. 101).

The cases reported above furnish conclusive proof

of the therapeutic value of entero-anastomosis in the treatment of intestinal tuberculosis, sufficiently limited to warrant surgical interference and beyond the reach of successful treatment by more radical measures.

Complete physiologic exclusion.—Practical experience has demonstrated the value of partial physiologic exclusion in the treatment of certain forms of localized intestinal tuberculosis. It would be natural to assume that the therapeutic value of entero-anastomosis would be enhanced if the affected part of the bowel could be completely excluded from the fecal circulation, thus securing for the diseased tissue a condition of absolute rest. At the time the writer made his experiments on physiologic exclusion of parts of the intestinal canal, he had this object in view and made a number of experiments to demonstrate the possibility and practicability of the procedure. The exclusion was made by isolating a section of the intestine and closing its ends by invagination and a few Lembert's sutures. The continuity of the intestinal canal was restored by circular suturing or lateral anastomosis. The results of these experiments proved unsatisfactory, as it was found that the retained intestinal secretions constituted a source of danger. A few years later, Salzer modified the operation by establishing a fistula in connection with the excluded portion. This method of effecting complete physiologic exclusion has been resorted to only in a very few cases in the surgical treatment of intestinal tuberculosis. I will limit myself to a detailed reference to v. Eiselberg's case.

In a case of tuberculosis of the cecum, ascending colon and hepatic flexure, this surgeon ("Zur Casuistik der Resectionen und Entero-anastomosen am Magen und Darmcanal," *Arch. f. Klin. Chirurgie*, B. 54, Heft 3), resorted to complete physiologic exclusion, with temporary benefit. The patient was a man 35 years old, who was in good health until five years ago, when a tubercular affection of the foot developed, followed soon by symptoms of acute pulmonary tuberculosis. Three years ago, the head of the tibia was operated upon by curettage, for tubercular caries. During the healing of the wound the patient suffered from an attack of perityphlitis, from which he recovered, but the disease was followed by periodic pains in the ileo-cecal region, at short intervals. During the last few months the pulmonary symptoms became aggravated and an obstinate diarrhea set in. On admission into the hospital, examination revealed extensive tubercular infiltration of left apex of lung and a cylindric swelling in the region of the cecum; the swelling was somewhat movable and tender on pressure. Operation was commenced, by making an oblique incision directly over the cecum. The cecum was found smaller than normal and not adherent. The infiltration extended from the ileo-cecal valve to the middle of the transverse colon. The affected portion of the bowel was completely excluded and the continuity of the intestinal canal restored by circular suturing, the resected end of the ileum had to be joined with the transverse colon. The mucous membrane, at the points of section, appeared to be healthy. The ends of the excluded portion were fixed in the upper and lower angles of the wound, respectively, and the balance of the abdominal incision was closed in the usual manner. From the excluded portion of the intestine mucus and pus escaped in considerable quantities. The patient improved temporarily. On the seventh day the affected part of the bowel was washed out

carefully, from both ends, with a warm physiologic solution of salt. These irrigations proved the competency of the ileo-cecal valve. The flushings were found useful in diminishing the amount of the inflammatory product. The patient left his bed in three weeks. A few days later the pulmonary symptoms became more marked and when the patient left the hospital, a week later, he was attacked with pulmonary hemorrhage, which recurred several times and from the effects of which he died two months after the operation. Diarrhea reappeared soon after the operation and continued to the end. The persistence with which the diarrhea continued soon after the operation tends to establish the existence of the tubercular lesion of the mucous membrane beyond the limits of the operation.

Complete physiologic exclusion will, in all probability, have a very limited scope in the surgical treatment of intestinal tuberculosis, as the immediate dangers to life are almost equivalent to the risks incident to resection and the advantages over those of partial exclusion are not sufficient to warrant a more general recourse to this procedure. There can be but very little doubt that with an increased knowledge of the etiology and pathology of intestinal tuberculosis surgeons will be induced to resort to operative treatment more frequently in the future, and that with further improvements in the technic of intestinal operations, the surgical treatment will yield more encouraging results.

ORIGINAL ARTICLES.

WHERE THE WEAK-LUNGED OR CONSUMPTIVE AND NEURASTHENIC MAY LIVE AND ENJOY LIFE.

BY W. S. WATSON, M.D.

RIVERVIEW SANITARIUM FOR NERVOUS AND MENTAL DISEASES.
FISHKILL-ON-HUDSON, N. Y.

OBSERVATIONS.

My object in writing this paper is to call attention to conditions, localities and influences that are beneficial to certain classes of sufferers, basing my conclusions upon my own observations and the statistics and observations of others.

It is impossible for all men to be rated by one general rule, nor will one climate suit all conditions. There is a distinctive individuality that does not allow a fixed or arbitrary procedure, men differ in their constitutions, temperaments, likes, dislikes and necessities as they do in their faces and forms. A climate favorable to long life is the one thing sought by man. The question is, where can I go to prolong my chances of life, suffer least and get the most enjoyment out of the time allotted me? Thousands are asking these questions, the consumptive perhaps more than any other, since consumption is the greatest scourge of the human race. Another class is the rheumatic, then comes the ever-present nervous individual with his many troubles, insomnia, etc. It is in the interest of these several classes that I write.

Among civilized people in temperate regions consumption, it is said, carries off one-tenth of the population and, so far as we know, there is no country entirely free from its ravages. In Iceland the disease is rare, while in the West Indies it is of common occurrence. This shows that heat is not a preventive and that cold does not necessarily produce it. That medicines are of but little, if any, use can scarcely be doubted. Cod liver oil and immunized serum are of

little or no value, climate is the one thing most promising.

I do not favor a cold climate for a sick man; a low temperature is especially detrimental to the phthisical or consumptive, notwithstanding there are strong advocates of the North, as the Adirondacks. Many cases are very much braced up for a time in a cold climate; the electro-positive conditions tend to make the depressed and jaded person feel better, but it is absurd to send a person suffering from consumption into a cold climate, as he is of necessity a person with impoverished blood, enfeebled circulation, and to place him where he must be shut up in-doors, week in and week out, and expect any lasting results for good is beyond my comprehension. I will concede many try and are much of the time out in the cold air of northern resorts, as the physician often insists that it is positively necessary to remain out. The out-door air is necessary but more aid in the attempt than get any lasting benefit from such ventures. While I do not approve of cold high altitudes and extreme changes, I also do not see a fitness in warm humid climates for the consumptive. I have sent many cases of consumption to Georgia, Florida and South Carolina in years gone by. In a few instances they have been benefited, but more frequently were not.

Aiken, Summerville and Thomasville, all of which have admirable climates in comparison with central or northern New York, for the comfort of the consumptive, but the variations are even there too marked, changes are too abrupt to be what is desired. The pine forests are no doubt beneficial and soothing, by reason of the ozone and sweet resinous odors of pine; this is especially true of bronchial troubles. The middle Southern States are better for the nervous class than for the consumptive. We have traveled over the Southern States at different times; I also visited the Territory of New Mexico with the express view of learning, if possible, of its value as a health resort for the consumptive. My first stop was at Eddy, located in the Pecos Valley at an elevation of about 3,000 feet. Here I found a clear sky and lovely climate and without the extreme changes of Northern regions; here we found many persons in the various stages of consumption (so claimed) that had come for relief, and that were to all appearances enjoying fair health, at least so long as they remained. To sufferers from, or rather those fearing lung troubles, New Mexico offers conditions favorable to the non-development of pulmonary diseases. It is a climate suited to cases before the destructive stage has arrived. Here is found a dry, aseptic air, a light atmospheric pressure, a large amount of sunshine and dry porous soil, and it is never too hot when one is shaded from the sun. The air is fresh and stimulating, the prevailing winds traverse a large expanse of arid regions and is consequently freed from all dampness; hence one can be out of doors a large share of the time, an almost positive necessity for persons with weak lungs. My observations were such that I would recommend the Pecos Valley to those persons who have not yet reached the stage of lung desintegration. My advice is to go there and engage in farm and stock raising, either of which offers large returns to the industriously inclined. Land is cheap and can be had on easy terms. Farming in New Mexico under irrigation is pleasant as well as profitable. I think that for the class named no better climate need be looked for; but once the disease has developed and

there are cavities in the lungs I doubt the propriety of going to New Mexico at the present or for some time to come.

New Mexico has high winds which come up suddenly, as is always true of timberless countries; the soil is dry and loose by reason of little or no rain and consequently there is but little grass or other growth to prevent the winds gathering up the dust and loose earth; hence dust and sand storms are not infrequent, though becoming less frequent and less terrible in character as the lands are brought under cultivation by the help of irrigation. During the time of high wind the air is full of dust, driving all persons in-doors, often for some hours, and even in-doors the air is full of dust particles which prove deleterious to an inflamed and highly sensitive tissue or mucous surface. When one is caught out in these storms, even if free from any lung weakness, the sense of suffocation is dreadful to say nothing of the feeling of bronchial irritation which follows and continues for some hours. Such foreign matter certainly can not act beneficially upon diseased tissues, therefore I do not think New Mexico the country for a fully developed case of consumption. I believe, however, that the time will come when it will be largely the resort for consumptives by reasons of the changes that will be wrought through irrigation and by reason of its nearness to the now populous portions of the States.

Before giving my conclusions relative to Mexico as a resort or home for the consumptive I will endeavor to disabuse the public mind of much that is false relative to Mexico and the Mexican people. It has been well said that "Mexico is a land of romance and wonder and that every noted spot has its legend." An extended description of Mexican life and customs would require too much time and space. I had an ungenerous opinion of this near-by land, having throughout my life heard only unfavorable criticisms. My first impressions were varied; the longer I was with the Mexican people and the more carefully I studied them the more favorably I was impressed toward them and their unique country.

Mexico may well be styled the Rome of America, not strictly on account of her temples and palaces, but on account of her churches and other ecclesiastical buildings, many of which have been alienated from their original purpose. Everywhere, in all the Indian towns, the grand Gothic cathedral rises above all else. In the metropolis the cathedrals are conspicuous, many of them grand, commodious and imposing. Public monuments are on every hand, many are real masterpieces. Upon the grand boulevard extending from the Alameda to Chapultepec, a distance of three miles, are numerous monuments to the memory of Aztec kings, also to King Charles, Columbus and others. There is in Mexico a strong educational interest manifest; excellent facilities in this direction are afforded at the capital by a school of fine arts, professional schools for women as well as men, an academy of fine arts, a conservatory of music, school of mines, school of jurisprudence, military institute, medical and commercial colleges, preparatory school for boys, deaf dumb and blind institutes, national museum, a superb public library with over two hundred thousand volumes. President Diaz has an idea to thoroughness, as is evinced by his prescribing a seven years' course in the national schools, the college of agriculture and college of engineering. The course includes French, English, German, Greek and Latin, geog-

raphy, meteorology, chemistry, botany, geology, architecture, agriculture, surveying, bookkeeping and political economy. The medical course is seven years. Musical culture is a prominent feature in Mexico. One of the noble institutions is the school of arts for women; in this school poor girls have unequalled advantages for learning. The government gives them a comfortable room and two meals a day. Many of the poor are supplied with clothing. Can the United States boast of a nobler benefaction? As regards civility and politeness, they are certainly the most polite people I have ever seen, with universal respect for age, genius and their superiors. Hospitality is a national characteristic; a leading inspiration among them is to make home beautiful; to this end every element of refined taste and culture is brought to bear. Americans may well copy their taste in floral and other home decorations.

The Republic of Mexico is a much misunderstood country; although near us, it has seemed to be a far off land, without merit, beauty or other attraction; its inhabitants a people that are strangers to hospitality, who live within and for themselves, whose prejudices are deeply rooted by reason of a never-to-be-forgotten unpleasantness that cost them many lives and much territory. Such I am happy to say is a misconception. A more liberal, hospitable people are not to be found. Instead of repelling they invite you to come, they ask that Mexico be better known, they seek investigation of their great country, the advantages of climate, etc.

Before giving any specific information relative to Mexico as a health resort it is well to briefly discuss what is, or should be, the accepted conclusions as to effect of climate upon certain diseases. The chief factors that act beneficially or adversely upon the consumptive.

Phthisis is the most important of all diseases for the amelioration of which climate is sought and over which, I think, temperature and humidity are ruling factors for good or evil, and that dryness is beneficial, humidity obnoxious and cold dangerous. Sunlight is a feature to be sought after by all classes of invalids and neurasthenics, but more especially is it a requisite to the consumptive.

There is little or no necessity for our dwelling to any extent upon the value of out-door air and sunshine; everyone acknowledges its benefit, though in the summer they may have a preference for the shade. The effect of light upon man's physical and moral well being is certainly analogous to the fructifying influence of the sun's rays upon the vegetable world, the existence of which depends upon light. Sunlight, clearness, transparency of air are certainly indications of purity. An atmosphere through which one can see a great distance, as in the high altitudes of Mexico, surely implies purity, absence of dust, smoke and moisture. Absence of moisture implies absence of infusoria and low forms of organisms. The changes of atmosphere in high altitudes are largely dependent upon electric conditions. There is an increase of electric tension, a higher potential quality as we gain in altitude; in other words, the dryer the air the more positive are the electric currents that surround us. Positive currents are stimulative, while negative are non-stimulating. It is only in the high, dry altitudes that we get positive electricity, hence the universal expression uttered by every one visiting high altitudes, "how light and buoyant I feel; this climate

seems to just lift me up, I feel that I have a great weight removed from me, etc."

The high-level resorts are being more and more appreciated and there is an increasing tendency to go to high altitudes. Seashore resorts are much less sought than they were ten years ago, unless it may be by those having no special need other than change from home and its environments.

The chief points of importance in climatic conditions are those favorable to non-development, retardation and cure of consumption, which are dryness of air, freedom from micro-organisms, irritants and noxious gases, the largest amount of sunlight practicable, diminished barometric pressure, ozoniferous atmosphere, and chief of all a climate that admits of an out-door life the largest possible amount of time. I am sure that high altitudes in a southern latitude are the only safe resorts and afford the advantages enumerated.

I believe portions of the Republic of Mexico, the high table lands at an elevation of from 3000 to 7000 feet above the sea level offer more and better advantages than any other country. When all is considered Mexico has climatic conditions suited to almost any possible condition that can exist, since temperature and barometric pressure depend entirely upon elevation, as do also humidity and dryness. In the high altitudes there is a positive freedom from sudden changes of extreme character, by reason of the lofty and continuous mountain ranges that surround the plateau lands of the republic.

In most of the mountain resorts of the world there are one or more serious objections to recommending them as a constant home or even as a temporary resort. In northern climes the extreme low temperature is inconsistent with out-door life a large portion of the time, which is a serious objection. No medical man can conscientiously advise a cold climate for an invalid, much less for the consumptive. Another objection to high altitudes in northern climes is the sudden fall of temperature, a thing that is dangerous to an enfeebled constitution. A low, humid, hot country is equally detrimental or nearly so as that of a cold frigid one.

Portions of Mexico and New Mexico are well adapted to certain classes of nervous cases and to the improvement of pulmonary conditions. Why? By reason of the high altitude that may be attained, the air being aseptic, free from dust, irritation and low forms of organisms or microbes; by reason of the rapid evaporation of morbid secretions in the lungs promoted by the reduced barometric pressure and the dryness of the air at the elevation named, the increased oxidation of the blood and tissue changes are due to increased metabolism, dependent on the sunlight of the high altitudes and lessened air pressure; by the increased quantity of blood circulating in the lungs due to the low air pressure of the high altitudes. In high altitudes there is an increase of blood circulating through the lungs, hence increased metabolism and tissue changes. The increased activity and deep breathing attendant upon a life in high altitudes tend to improve nutrition and glandular secretions. Along with the local and general nutritional effects that are manifest from a sojourn in the high altitudes of Mexico are the delightful and stimulating effects upon the nervous system. Still another noticeable feature and one much to be desired, is the increase of red blood corpuscles and hemoglobin. Such blood

changes are unquestionably due to increased amount of oxygen inspired. Anemic conditions rapidly disappear in the sunlight of Mexico's high altitudes: rapid and remarkable improvement in the local and general conditions are coincident with the blood changes in the consumptive who is transported from the sea level to altitudes of three or more thousand feet, as has been demonstrated by numerous careful observations in Europe, North and South America.

So far as we know the only successful means of combating tuberculosis is by improving the resisting powers of the system. Out-door life in a mild, dry climate where the general health can be kept at the highest possible standard offers certainly the best possible advantages and the longest immunity. The high lands of Mexico certainly offer all that can be desired in point of climate, being neither hot nor cold, and is as near as possible suited to each and all cases. Whatever rainfall takes place in Mexico is between the months of April and November, just when needed to cool the otherwise long and occasionally dry season, most of the showers occurring during the night hours consequently seldom interferes with out-door exercise, sports or employment. The opportunity for profitable employment is a strong argument in favor of Mexico and New Mexico; lands are cheap in either country and profits large. The accommodations for invalids are meager. The hotels are not, as a rule, what they ought to be and are not generally favorably located for the invalid class, nor are they built with any thought of providing open air exercise or sun baths. The hotels are in the midst of the noise and din of business. That no provision has been made for the invalid class is due to lack of demand; the people of the North that need just such a climate have never had their attention called to Mexico. The day is near at hand when the sanitariums for the people of the more northern sections will be in the Mexicos. The land of the Montezumas needs only to be seen to be appreciated, the enchantment grows with your stay in that balmy land. While there are English-speaking people to be found almost everywhere in the republic and especially in the City of Mexico, your comfort will be largely increased if you have sufficient knowledge of the Spanish language to understand and be understood.

CLASSIFICATION OF THE LESIONS CONSTITUTING THE SO-CALLED CHRONIC NASAL CATARRH.

Read before the Chicago Medical Society, Jan. 5, 1898.

BY H. GRADLE, M.D.
CHICAGO, ILL.

The term chronic catarrh was formerly used for all chronic affections of the nose manifested by more or less nasal obstruction and secretion. It is still so employed by the public and to some extent by physicians, yet the studies of the last twenty years have resolved this comprehensive name into a number of separate affections. The description of these various types of disease is, however, neither uniform in different text-books on the nose, nor do the types stated by authors conform always with actual observation. Perhaps the main reason for these discrepancies is the frequent multiplicity of lesions, so that quite commonly the symptoms of catarrh depend on several different morbid conditions co-existing in the nose.

My object is to classify the different lesions which

make up this composite picture of catarrh. On the basis of many years' personal observation I wish to describe those types of morbid changes which constitute each a separate disease entity. Although these are often found in combination I shall base my description on cases which present the least number of lesions and hence the purest type of each disease.

The different lesions which simply or in combination make up the clinical picture of chronic catarrh may be grouped as follows: 1, enlargement of cavernous tissue; 2, simple nasal catarrh; 3, nasal suppuration, localized in nasal passages, accessory cavities, or the pharynx; *a*, rhinitis sicca anterior (perforating ulcer); *b*, ozena or atrophic rhinitis; 4, hypertrophic inflammation of mucous membrane and adenoid tissue; 5, septum deformities in the form of deflection, articular expansion or callus formation.

1. *Enlargement of the venous plexus* in the mucous membrane occurs in connection with all (except the atrophic) forms of nasal disease, but may exist in a nose not otherwise diseased at the time. It hence deserves to be described as a separate lesion. Its significance depends less on the permanent increase of vascular tissue than on its periodic dilatation under the influence of various stimuli. These periodic changes of turgescence cause the variable obstruction or even occlusion in nasal diseases. Except in acute inflammations the vascular distension is only considered at a time: but alternating. The area where the veins are massed in the form of distinct cavernous tissue is the front region of the inferior turbinal and the posterior ends of all the turbinates. Enlargement of the cavernous tissue is not identical with hypertrophy of the mucous membrane and can be distinguished from it by the compressibility on pressure with the probe and by the contraction under the influence of cocaine. It may, however, co-exist with moderate tissue hypertrophy.

The influence of the vaso-constrictor nerves upon the cavernous tissue is sometimes shown by its contraction under the effect of anxiety during an examination. Whether there are also vaso-dilator nerves is not known. Although enlargement of the cavernous bodies is mostly but a concomitant condition in other nasal diseases, yet it is sometimes found where no other lesion can be detected, especially in hay fever. As far as can be learned clinically, it is the result of often repeated attacks of acute inflammation in subjects with unstable nervous systems. Indeed vascular dilatability is the direct expression and, to some extent, a proportionate index of a neuro-pathic condition. In extreme instances sudden engorgement with sneezing and profuse watery flow simulates attacks of true coryza, but its non-inflammatory nature is shown by the short duration of the spell, as well as by the absence of corpuscles in the clear discharge.

2. *True nasal catarrh* is characterized by catarrhal secretion, a thick, viscid, turbid fluid, containing enough cells to make it appear whitish or gray, but not yellow or green and not at all purulent. In cities the discharge is commonly stained by inhaled soot and dust. This discharge flows over the soft palate and drops into the throat or is dislodged by forcible expirations which vibrate the palate. It is not blown out of the nose. Nasal discharge blown into the handkerchief is either purulent or a sudden flow of clear transparent mucus in consequence of acute irritation. Although nasal catarrh, described by the patient as a "dropping in the throat," is the most common form of

nasal disease in this climate, I do not know of any accurate description of it in literature. It is usually classified as chronic hypertrophic catarrh, but the description does not conform to the reality. Various forms of hypertrophy frequently occur with true catarrh, but they are not a constant and hence not an integral factor. In uncomplicated cases of true catarrh there are no gross lesions visible to the eye. Yet I do not know of any author who has defined chronic nasal catarrh in this manner.

What, then, is the pathology of simple chronic catarrh? In those few instances in which it can be traced from its beginning, it is found to be the sequel of an acute coryza. Moreover, it is always intensified when the patient passes through a fresh acute nasal inflammation. This history suggests that it is due to a persistence of chronic inflammation. As far as can be learned clinically, the process is localized in the posterior and lower part of the nose. But in the pure type of the disease the inflammation does not reveal itself by either redness or swelling of the mucous membrane, at least as seen during life by anterior or posterior rhinoscopy. In view of the fact that the catarrhal secretion persists in some patients for many years without being followed by any visible tissue alterations, the term hypertrophic catarrh does not seem appropriate. Moreover, the hypertrophic areas which are often found associated with simple catarrh are not necessarily the source of any secretion.

Bosworth has emphasized that an important factor in nasal catarrh is stenosis of the nasal passage, especially when due to irregularity of the septum. The amount of catarrhal secretion and the annoyance to which it gives rise are more or less proportionate to the narrowness of one or both sides of the nose. But I can not accept Bosworth's view, that the secretion is the direct consequence of the stenosis. Stenosis of variable degree may exist by itself without nasal catarrh or secretion, especially in young persons under about 16 years of age, in whom nasal catarrh is quite rare. Adults, however, who have nasal stenosis, quite commonly acquire catarrh in addition, which proves persistent. On the other hand, I have observed chronic catarrh in noses which were not at all stenotic. The only method of estimating nasal stenosis is to listen to the sound produced by breathing through one side at a time. A normal passage allows the air to pass in and out without any sound whatever, while interference with respiration gives rise to a noise which varies from a gentle blowing to a sharp hiss. I regard stenosis as an important determining condition, which favors the persistence of chronic inflammation in the posterior parts of the nose, but not as an indispensable factor in catarrh. All operative procedures against stenosis relieve the catarrh in proportion to their mechanical influence upon the caliber of the nasal passage. Of similar importance are the transient occlusions due to vascular engorgement; hence removal of excessive cavernous tissue by snare or cautery is a valuable remedial measure in suitable cases.

The surgical cure of stenosis does not cure the catarrh. The secretion, though much diminished, still persists. As the patient feels very little annoyance from this when the nose is freely patent, he is generally satisfied, but the catarrhal secretion is there. I know of no method by which we can absolutely cure chronic nasal catarrh; it may however disappear in the course of time or under favorable climatic influ-

ences in noses without stenosis, or after successful operation for stenosis.

3. *Nasal suppuration* is separate and distinct from nasal catarrh. Its secretion is pus diluted with more or less mucus, and chronic pyogenic infection always involves a possibility of mischief by extension. The source of the pus may be in the nasal passages, in the accessory sinuses or in the pharynx. Gruenwald has shown clinically that chronic suppurative inflammation in the nose is usually not a diffuse process, but localized in some small area. In many of his cases he claims to have found caries or superficial ulceration of the bone as the lesion which explained the persistent suppuration. I have seen very little confirmation of this part of Gruenwald's view and I do not think that the information which he gets from the use of the probe is as trustworthy, regarding bone disease in hidden parts of the nose, as he claims. I also do not admit the existence of Woakes' necrosing ethmoiditis as a common lesion in nasal suppuration. My doubts are fully confirmed by the recent pathologic studies of J. N. Mackenzie and of Hajek. In seventeen amputated fragments of the middle turbinal, in the class of cases attributed by Woakes to necrosis, Hajek did not find bone destruction. anatomically, in a single instance. Destruction of bone does, however, occur in some of the more severe forms of suppuration of the accessory cavities, but such cases are relatively rare. The more common cause of osseous necrosis is syphilis in its late manifestations. A purulent discharge may also be due to foreign bodies and concretions in the nasal passages. Another cause for the persistence of purulent inflammation is the lodging of pus in various recess-shaped areas and in such regions where accidental configuration favors a damming up of pus; by reason of such imperfect drainage, acute attacks of coryza lead to the persistence of localized suppurative inflammation.

While disease of the accessory sinuses was considered scarcely more than a surgical curiosity until some ten years ago, anatomic work by Harke, E. Fraenkel and others has shown the frequency of acute affections at autopsies. Probably most of the milder acute cases escape clinical detection and heal spontaneously, but the more our methods of diagnosis become perfected, the larger do we find the proportion of diseased nasal accessory cavities as the source of nasal suppuration. It is beyond the scope of this paper to discuss the methods of diagnosis and treatment. While the more severe "text-book" cases of sinus suppuration can now be readily recognized, it often taxes the patience and ingenuity to determine the source of pus in the less pronounced forms. In the milder forms of even chronic suppuration from the frontal, ethmoid or sphenoid sinus, a cure can sometimes be obtained without surgical exposure of these cavities, if by minor surgical intranasal measures we can improve the drainage.

Pus secreted in the nose, the ethmoid cells or the sphenoid sinus may flow into the pharynx, as well as out of the nose anteriorly, where the configuration of the passages favors the flow toward the rear, but pus in the pharynx may also be formed in this space itself. Its source, in such cases, is the inflamed adenoid tissue at the roof, the pharyngeal tonsil. Mere enlargement of the adenoid tissue does not necessarily cause suppuration; the tissue must be besides in a state of inflammation. An enlarged pharyngeal tonsil does not suppurate continuously, although it does

so very often. On the other hand, there may be purulent inflammation at the pharyngeal vault without enough hypertrophy to cause the symptoms of obstruction.

In certain cases the morbid discharge formed at the roof of the pharynx dries in the form of adherent crusts. As a rule, we find in such instances only a slightly thickened layer of adenoid tissue. Sometimes the secretion issues from clefts in the adenoid tissue, the surface of which appears healthy. Whether some of these instances are not cases of ozena localized in the pharynx, is an open question.

3a. *Rhinitis sicca anterior of Sieberman*, a special form of nasal suppuration, is a disease limited to the anterior lower part of the surface of the septum. In this affection (usually one sided) the discharge forms a thin adherent scab on the septum, without any odor. Characteristic of the disease is the viscid secretion which, while scant and purulent, dries in so firm a manner that it can not be detached without injury to the epithelium, hence its removal leaves an abraded surface. A further peculiarity is the extensive hyaline degeneration of the involved mucous membrane. (Ribari). This form of disease causes but little subjective annoyance, but it is a frequent source of recurrent nose-bleed. More important, however, is the possibility of ulceration of the septum, for there can be but little doubt that the perforating ulcer of the cartilaginous septum is the occasional consequence of this disease, if not controlled by treatment. This typical form of ulcer has certainly no relation to either tuberculosis or syphilis.

3b. *Ozena* is another variety of suppurative inflammation of specific character. It is characterized by progressive atrophy of the mucous membrane and turbinate bones, and by a thick purulent secretion drying in crusts, which when allowed to remain give rise to a characteristic fetid odor. The peculiarities of this disease are so pronounced that most observers consider it as a separate affection, but its pathology is not yet clear. The older view, now almost discarded, that it is the terminal stage of hypertrophic inflammation, is unfounded. No one has seen the transformation of a pronounced hypertrophic rhinitis into an atrophic stage. Hypertrophies are common, ozena is relatively infrequent. Moreover, it usually begins in early life. Ozena occurs more commonly in relatively short and wide nasal passages, as Hopman has shown, while hypertrophy is favored by stenosis.

Ozena has been ascribed by Michel, and especially by Gruenwald, to suppuration of accessory cavities, or to circumscribed nasal foci of suppuration. Against this view it can be urged that autopsies have shown that the sinuses are not always involved, but that the greater extent of the mucous membrane is diseased. Undoubtedly sinus suppuration is a frequent and important complication in ozena, but it is only a complication, and one not always present. The microscopic changes in the mucous membrane are, flattening of the epithelial cells and fatty degeneration extending into the mucous glands. The inflammatory nature is shown by round cell infiltration, while fibrillary sclerosis of the mucous membrane leads ultimately to its shrinkage and to atrophy of the bony structures.

The symptoms and course of ozena suggest as its cause some specific microbe. A well characterized bacillus has been described by Loewenberg and studied by Abel, yet in view of the occasional occurrence

of this bacillus without ozena, and in the absence of conclusive inoculations, its etiologic role can not be called well established. It is probable that the odor of the discharge is a secondary feature, due to the proneness of this peculiar pus to a certain form of decomposition, for by treatment the odor may be removed even without a complete cure. There is, moreover, a form of atrophic purulent rhinitis identical in course with mild ozena, but without the presence of odor.

4. *Hypertrophic inflammation* is described separately from simple nasal catarrh, as I do not consider the two affections identical. Many cases of catarrh are not accompanied by any hypertrophy, while hypertrophies are sometimes seen without catarrhal secretion. Moreover, when the two conditions co-exist the areas of hypertrophy are not necessarily the source of the secretion. We must distinguish between hypertrophies of mucous membrane and of adenoid tissue.

Hypertrophy may involve diffusely the mucous membrane of the inferior and middle turbinal, or may be circumscribed in small areas in the form of tumors. Diffuse hypertrophy can be easily distinguished from mere enlargement of the cavernous tissue by the relative incompressibility and the persistence of the thick cushion after the use of cocaine. The hypertrophied membrane is usually pale in color, rarely injected. A peculiar appearance is presented when hypertrophied mucous membrane is edematous; it then appears jelly-like and pellucid. This has been incorrectly termed myxomatous degeneration. The edematous condition, however, is shown by the great shrinkage of excised pieces when placed on blotting paper. Diffuse hypertrophic inflammation gives rise to no symptoms beyond those dependent upon the stenosis which it may produce.

Circumscribed hypertrophies assume various shapes according to their site. On the front end of the inferior and the inferior edge of the middle turbinal they appear as flabby overgrowth. Along the middle of the inferior concha and sometimes on its posterior end the tumors are papillomatous in gross appearance, often resembling raspberries in shape and color. On the posterior ends of inferior and middle turbinals hypertrophies are usually associated with cavernous enlargement and present rounded, grayish, gelatinous looking masses which may seem wrinkled when partly collapsed, but bag-like and bluish when engorged. A form of hypertrophy which has been described by some of the older writers (Solis Cohen and Voltolini), but which is very little mentioned in recent literature, is in the form of a grayish cushion on the surface of the septum close to its posterior edge. The best known growths however are polypi, which spring from the external wall in or above the middle meatus, or from one of the surfaces of the middle or superior turbinals. It is not correct to call these tumors myxomata or fibromata. They are histologically the equivalent of any other form of inflammatory hypertrophy of the mucous membrane. The gelatinous polypi differ from the denser fleshy tumors only by their state of edema. There are however other polypoid tumors which are histologically different, sometimes mixed angiomas, sometimes malignant growths of polypoid shape.

The causes of hypertrophic inflammation are not fully known. In the case of polypi, suppuration, especially of the accessory cavities, is often a demonstrable etiologic factor, but this is not always the case. In some instances it can be observed that acute

inflammation is the determining condition, which is perhaps best shown by relapses of circumscribed hypertrophies in cases under continuous observation. In many instances, however, we do not understand why chronic inflammation persists and why it leads to overgrowth of mucous membrane.

Hypertrophy of adenoid tissue differs from the conditions just described, first, by its location, as it occurs only in the pharynx. It presents, moreover, this difference, that while of inflammatory origin at first the enlarged adenoid tissue, at least of the pharyngeal and faucial tonsils, is not necessarily in a continuous state of inflammation. This distinction is based on clinical data; whether it could be demonstrated histologically in adenoid tissue is perhaps questionable. We may thus observe tonsils which are enlarged, but pale, and cause no irritation for long periods of time, while in others the tonsils show by their congestion and liability to acute troubles that they are the seat of persisting inflammation. In the case of the pharyngeal tonsil the same differences may be observed, with the additional criterion that the enlarged but non-inflamed adenoid tissue in this location secretes only the normal clear mucus, while when inflamed it produces pus.

The most striking forms of adenoid hypertrophy are enlargement of the pharyngeal and the faucial tonsils. As far as etiology can be studied clinically it is evident that the over-development of adenoid tissue is the result of acute attacks of nasal inflammation. Where suitable opportunities are offered it can be observed that children with hitherto unimpeded nasal breathing get the characteristic stuffiness due to adenoid vegetations after severe attacks of coryza. The close relationship between nasal inflammation and the faucial lymphatic tissue is also shown by the not uncommon occurrence of acute tonsillitis from infection of intranasal wounds on the same side. Undoubtedly a certain predisposition favors the enlargement of the lymphatic tissue. This is suggested by the frequency with which it occurs in certain families and its absence in others. Clinical observation, too, suggests some relationship between hypertrophy of the pharyngeal tonsil and tuberculosis, but lymphatic enlargement is not a tubercular manifestation by itself, although various recent German and French observers have found that enlarged tonsils, both pharyngeal and faucial, may get tubercular by secondary infection, in perhaps one-sixth of all instances. This adenoid tuberculosis can not be recognized clinically, it is entirely latent. The common text-book statement that enlargement of the adenoid tissue is a manifestation of scrofula is very vague. It is more definite to say that some of the scrofulous appearances, the thick lips, the sub-acute catarrh, the eczema under the nose and the suppurative middle ear inflammation are the direct results of enlarged pharyngeal tonsils.

Besides, in the tonsils, hypertrophy of the lymphatic tissue may show itself as enlarged lingual tonsil, as separate follicles on the pharyngeal wall, and as thickened columns of adenoid tissue in the posterior lateral corners of the pharynx. In all these locations the hypertrophied tissue is usually in a state of inflammation and the source of decided discomfort. I have, however, not been able to satisfy myself that purulent secretion is produced in any locality except at the roof of the pharynx and by the lymphatic tissue over the root of the tongue.

The term chronic pharyngitis has hitherto been

used in a loose manner and often inappropriately. There is, however, a condition which fully deserves this name. It is characterized by persistent redness and thickening of the mucous membrane of the pharynx and annoys the patient mostly by the tendency to nausea and retching on slight local irritation. It occurs always in connection with some form of chronic nasal suppuration. Another potent etiologic factor, although not an indispensable one in this affection, is the abuse of tobacco and alcohol. It is hence rarely seen in women. On the basis of clinical data, I consider this affection as a diffuse inflammatory hypertrophy of the adenoid tissue which underlies the pharyngeal mucous membrane.

5. *Deformities of the septum* may be classified under three heads: *a*, deviations; *b*, articular expansions; *c*, callus formations.

a. Moderate curvature of the septum is so common that it can not be considered morbid. It is only an unfavorable structural peculiarity. Moreover, uncomplicated deflection of the septum, without additional malformation, causes stenosis only in narrow noses, where there is less than the average width between the two external walls. We know nothing definite concerning the conditions which lead to asymmetry. It is evidently the result of unproportionate growth of the septum and the bones with which it articulates. The deflection of the curved septum may be either horizontal or vertical, or exist in both planes.

b. The most common clinical malformations of the septum are projecting spurs, ledges or ridges, often but erroneously, termed exostoses. According to Zuckerkandl's extensive dissections, they are formed by overgrowth of the articulating surfaces of the various plates which make up the septum. The term articular expansion seems, therefore, an appropriate one. It is especially the strip of cartilage which persists during adult life on the upper border of the vomer, which expands. Being surrounded by bony walls this cartilaginous hypertrophy thus forms the nucleus of a bony projection on the side of the septum, while occasionally secondary ossification of the cartilaginous strip adds to the solidity. The usual site of these crests is along the upper border of the vomer, running in an oblique direction upward and backward toward the sphenoid sinus. A similar formation is found less commonly as a vertical ridge between the quadrangular cartilage and the perpendicular plate of the ethmoid. Such one-sided expansions are not rarely combined with deflection of the septum, which then presents an angular depression on the concave side and a protruding spur on the convexity. This malformation is often mistaken for a healed fracture.

c. Fractures of the septum are not common. It is doubtful whether they are possible without fracture of the bridge of the nose, and unless a characteristic flattening of the bridge is recognizable, the diagnosis of broken septum is questionable. Fracture of the septum usually leaves considerable deformity on account of the displacement and overlapping of the fragments.

The importance of deformities of the septum hinges largely on the stenosis which they cause. This in turn depends on the relative width of the nasal passages. Even when the nose appears normally patent during examination, transient stenosis may still exist during periods of engorgement of the cavernous tissue. But stenosis itself is not a disease. It is only

an important anomaly which predisposes to the persistence of chronic inflammation.

Irregularities of the septum may play a morbid role even without reducing the capacity of the nasal passage. An irregular septal surface favors chronic inflammation, perhaps by impeding the flow of morbid secretions. Hence, successful operations of septal deformities often prove of service even where no stenosis existed. They are not rarely the starting point of morbid reflexes, especially when the spurs are sharp, or when they come in contact with the surface of the turbinates.

For these various reasons operative treatment of septal deformities is often indicated and in the case of extensive malformation it is usually satisfactory. But the minor irregularities, and especially the deformities due to moderate septal deviation, are not so easily benefited mechanically. The novice can not be too strongly warned against attempting operations indiscriminately, as many of these fail primarily for mechanical reasons, or produce but a temporary result on account of relapses.

INJURY OF THE CAVUM PHARYNGEUM; REPORT OF A CASE.

BY EMIL ARONSON, M.D.

DALLAS, TEXAS.

Several years ago, while practicing in Europe I received a call to Mr. D., a gamekeeper, who had sustained an injury from the explosion of a gun. In the morning Mr. D. had tried his first experiment with his new gun. While the members of his family were looking on they saw him fall to the ground with blood oozing from nose and ear. He was carried unconscious into the house. After some time he regained consciousness but did not complain of the presence of a foreign body in his throat, yet his family thought it necessary to send for their family physician. This gentleman arrived, examined the throat and stated that except a piece of a tooth which was lodged in the posterior wall of the pharynx, nothing could be found. Promising to return in a day or two to remove that remnant of the tooth he left the house. Other relatives of the injured man, much surprised at the indifference of this gentleman, decided to send for me.

Inspection reveals the following conditions: Upper lip swollen, upper right incisors are missing; some loose fragments are hanging in the alveoli. The palate, the mucosa buccalis, the tongue, uvula and posterior wall of the pharynx are discolored, powder-stained and covered with coagulated blood; on the right side of the posterior wall in the region of the constrictor pharyngeus superior and medius is a mass of indistinct shape and color.

The gun consists of two long tubes which can be attached to each other. After placing the cartridge in one tube, the other tube is screwed on to it. At the end of this long tube the inventor inserted an iron bolt, he put the tube to his mouth and expected that by very forced expiration the bolt could be driven against the cartridge. His calculation failed to prove correct at the first trial. He did not consider that the moment the bolt and cartridge would meet explosive gases would become free, which, if no valve was provided, would drive the bolt back into the mouth of the experimenter.

Although the patient felt perfectly comfortable and there were no symptoms of stenosis, I managed to

make out a large, smooth, round, metallic body in the back wall of the pharynx. Trying twice, I failed to grasp this with a long forceps, due to the impossibility of pressing the points of the forceps into the hard iron bolt. I then took a long Langenbeck retractor and using it as a lever removed the bolt, which weighed nineteen grams and was four and a half centimeters long.

I prescribed an antiseptic gargle and directed ice and antipyrin for the intense headache, which appeared in the course of the week. In about ten days the patient was well again. A few conclusive remarks about the direction of the projectile: The upper incisors were struck first and knocked out. The projectile then changed its direction and passed through the oral cavity to become imbedded in the muscles of the pharynx, where it lodged on one of the vertebræ. It is remarkable and of value in regard to diagnosis, how very little pain was felt by the patient, who for more than twelve hours did not believe there was a foreign body in his throat. This case shows how valuable an objective examination is and teaches us not to rely entirely upon the patient's statements or upon the observations of Schroetter (notably, on "Diseases of the Ear," 1876 and 1882), who says that in such injuries of the pharynx the patients always claim to feel the foreign body in the throat.

DISEASES OF THE EYE CAUSED BY DISEASES OF THE NOSE.

Read before the Chicago Academy of Medicine, December, 1897.

BY ALLEN T. HAIGHT, M.D.

PROFESSOR OF OPHTHALMOLOGY CHICAGO EYE, EAR, NOSE AND THROAT COLLEGE; ATTENDING OPHTHALMOLOGIST AND OTOLOGIST TO THE GERMAN AMERICAN HOSPITAL; MEMBER OF THE AMERICAN MEDICAL ASSOCIATION, ETC.
CHICAGO, ILL.

There are no organs of the human body more closely connected than the eye and the nose. No organ suffers more from reflexes than the eye from the nose. The slightest offense to the mucous membrane of the nasal chambers will instantly cause suffering to the eye. Let one come in contact with smoke or other irritants to the Schneiderian membrane and the eye will soon respond to its danger and shed tears. The reason for this is clear, as the eye is directly connected with the nose by the nasal duct, the same mucous membrane, histologically connected, continues to cover the eye lids, the globe and the orbits.

The lachrymal artery with its branch, the anterior ethmoid, supplies blood nourishment to both the lachrymal sac and the nasal duct. The nerve supply is received in common from branches of the ophthalmic nerve and Gasserian ganglion. The lachrymal sac, the dilated part of the nasal duct, is situated in a channel of the nasal process of the superior maxillary and lachrymal bones. Its formation is fibrous and elastic, lined with mucous membrane, continuous with that of the nose. The membrane of the lachrymal sac and canaliculi is lined with pavement epithelium, but in the main duct the epithelium is partly of a cylindric variety. The middle lachrymal organ (Fig. 1) consists of a small double puncta, located from six to eight millimeters from the apex of the inner canthal angle, opening into the corresponding superior and inferior canaliculi, which meet toward the inner canthus in the lachrymal sac.

"The lachrymal secretion is forced through the puncta into the canalicula, then enters the sac and

finally, into the nose through the nasal duct by a combination of winking and the suction force of the Horner's muscle, and possibly of the muscular fibers given off from the orbicularis and the tendo oculi. The canaliculi and puncta, therefore, are not merely drains to carry off the lachrymal secretions, but in conjunction with the muscular fibers mentioned act very much as a suction syringe. These canaliculi are not perfectly straight; the mucous membrane lining them is like that of the nose¹.

FIG. 1.—1 and 3, orbital and palpebral portions of lachrymal gland; 2, fibrous band dividing the gland; 4 and 5, orifices and branches of the lachrymal canal; 6, lachrymal sac.

The nasal duct, which is about three-fourths of an inch in length, begins at the somewhat constricted portion of the passage where the sac terminates, and extends in an osseous canal formed by the lachrymal superior maxillary and lachrymal process of the in-

FIG. 2.—1, middle turbinate body turned aside and held by a hook; 2, nasal duct and valves; 3, canal leading to the maxillary and frontal sinuses; 4, inferior turbinate body showing location of the mouth of the nasal duct in the cul-de-sac.

ferior turbinate bone, in a direction differing almost (Fig. 2) in every case that presents itself downward, slightly backward or outward to the inferior meatus of the nose. Hence we have a direct route in the nasal

chambers for the passage of morbid germs from the rhinal cavities to the eye, and under certain pathologic conditions the nose becomes a factor for aggravating causes of ocular disturbances. The ordinary blood supply with anastomosis from the duct and sac, and the connected relation of the accompanying veins manifest that certain mechanical or pathologic conditions existing in the nasal chambers may produce pronounced symptoms in the eye. For example, an irritation of the Schneiderian mucous membrane may produce lachrymation, and more dangerous ocular disturbances often accompany coryza, measles, scarlatina, etc.

"Dr. Edwyn Andrew², M.R.C.S., says that the fluid of the lachrymal apparatus is continuous from the conjunctiva to the nose, and by the aposition of the lids to the eyeball and the attraction of adhesion and cohesion produced, a thin layer of tears is brought into contact with the cilia, and by them conveyed to the puncta, where capillary action of the canaliculi brings them within reach of the cilia and the lachrymal nasal canal, which pass them onward through the sac and nasal duct to the nose. This natural course of the tears is, however, easily changed, the power of the cilia is feeble and soon overcome by any increase or altered condition of the fluid in contact. Extra secretion is so easily excited through irritation of the branches of the fifth nerve, which supply the conjunctiva and lachrymal gland, that the whole lachrymal apparatus quickly becomes engorged with fluid, which if persistent, soon produce morbid changes in the adjoining mucous membrane. The irritation thus produced, which soon causes in the open eye change of the natural secretions to muco-pus or inflammation, ulceration, thickening of lids, inversion and eversion, closure of the puncta, etc., naturally becomes still more injurious to the almost pent up cavity of the lachrymal nasal canal, frequently converting it into an abscess, occluding the channel by exudation and causing stricture of the constricted portions, particularly at the entrance of the canaliculi into the sac, and at the junction of the sac and nasal duct."

Having examined the anatomy and physiology of the parts pertaining to the subject I will now proceed to the historical and pathologic comments of the best ophthalmologists of the present day, in addition to my personal observations. I will attempt to show that the eye specialist can not successfully treat the eye without attending to the nose. Foubert invented the lachrymal canula in 1819, on account of obstruction from polypi of the nose, but nothing can be found as to the results in his case, as very little is known of him.

Dr. J. Reeve, in 1821, in the "London Medical Repository," first called attention to diseases of the eye affected by the nose. In 1859 Chalons³ wrote on adenoiditis lachrymalis, but gave no description of his treatment except that of sounding and the usual eye water. In 1861 von Graefe⁴, in 1862 Carl Schweigger⁵, in 1863 Brueff⁶, in 1864 Minkiewicz⁷, in 1869 Vassoux⁸ and others, only alluded to diseases of the eye caused by diseases of the nasal chambers.

In 1887 Dr. A. Blitz⁹ reported before the Medical

Society of Tennessee a successful operation of extirpation of hypertrophy of the lachrymal gland extending from the nose, saving the eyeball with complete recovery. In 1878 a wide chasm occurred which can not be overlooked. Wm. Hack of Freiberg, with his renowned monogram, which the world must follow, has shown not only that we have migraine, asthma, hay fever, etc., but that the eye also suffers in consequence of the obstruction of the olfactory canal.

Hack, and many others since his time, have only superficially mentioned the subject until in 1886 Dr. Greening¹⁰ in an article on "Reflex Ocular Symptoms in Nasal Afflictions," gave the first elaborate description of ocular symptoms caused by obstruction of the olfactory canal, and points out that photophobia may be readily produced by touching certain parts of the Schneiderian membrane with the sound, and *vice versa*, reflex nasal symptoms, for instance, sneezing may be effected by exposing certain eyes to the bright light. The leading ocular symptoms, which in certain cases depend mainly on the pathologic conditions existing in the nose, are lachrymation, photophobia, conjunctival hyperemia, pericorneal injection, smarting or burning and swelling of the lids, phlyctenular disturbances, epiphora, etc. In addition to the symptoms I have described I recommend as a guide to the ophthalmic practitioner the systemized ocular symptoms, depending upon pathologic conditions of the nose by Dr. Gradle¹¹, which are as follows: "1, lachrymation without primary lesion of the tear passages of the eye and due to some chronic abnormality of the nasal passages; 2, fulness of the lids and itching, possibly with lachrymation and more or less pain, and with asthenopia especially marked in one eye. Patients with these symptoms aggravated have also a refraction or muscular anomaly; 3, periodic discomfort (itching of the lids), allied to hay fever, or coexisting with conjunctival lesions, at first of the follicular enlargement and finally of a formation of large, flat, yellowish follicular granules which disappear in winter; 4, photophobia, with or without pain in the eyes, these being often blood-shot with little nasal annoyance but with decided itching; 5, injection of the pericorneal vessels together with varying degrees of the above symptoms, chronic and persistent; 6, acute congestion of the lids with irritable nose, erysipeloid in character, subject to recurrence, lasting from two to six days; 7, sudden edema of lids without congestion, the attack lasting a few hours."

I shall now confine the principles of the subject to two classes; first, pathologic conditions of the eye depending on hypertrophies, deformities or mechanical abnormalities of the nose; second, pathologic conditions of the eye resulting from the passage of morbid material from the nose through the nasal duct or intermediate tissue of the eye.

One of the frequent causes of ocular disease is chronic hypertrophic rhinitis, especially in that form in which sudden dilatation of the blood vessels of the mucous membrane is apt to recur from very slight irritation. In such cases we have a copious aqueous discharge from the nose with severe inflammation of the inferior turbinated body, especially marked in the anterior half, associated often with mucous polypi in the middle meatus. Eye symptoms occurring with this condition of the nose are lachrymation, photophobia, burning and smarting of the lids with deep injection,

particularly marked at the margin, and not infrequently ciliary and conjunctival injection. Polypi of mucous region situated so as to form a wedge between the septum and inferior turbinal, or situated so as to fill the superior meatus, give rise to persistent ocular lesions; deviated septum, spurs, fissures, post-nasal adenoids and synechiæ play an important part in the production of sympathetic ocular conditions.

Dr. Charles Michael describes a case of ectropion of both lower lids caused by complete obstruction of the right and left lachrymal passages, which was operated upon by him in a manner not found in the textbooks or reported in literature. He says the patient was 62 years of age. There had been complete obstruction of the passages for periods of ten and twenty-eight years respectively. Dr. Michael received the idea of the operation in Paris in 1859, but did not bring out his method until 1871. For ten years he continued it and was successful in every case. He gave up the old method of introducing a canula, and believed that the only correct method of treatment of obstructed lachrymal passages was to clear the nasal cavity and secure a permanent dilatation between the nares and lachrymal duct, so as to allow a free exit of the secretions coming from the conjunctival surface and lachrymal canal.¹²

Bishop cites a case of amblyopia of the left eye cured by the removal of an osseous synechia between the left turbinated bone and the nasal septum.¹³

Dr. Bettman¹⁴ reported a case of constant epiphora, which he cured by extirpating the hypertrophied tissue of the anterior portion of both turbinated bones.

The six cases reported by Hamilton and quoted by Gould are as follows:

Case 1.—Empyema of the antrum and unilateral hypertrophic rhinitis of the left side attended with the following eye symptoms: 1, concentric contraction of the visual fields for all colors; 2, accommodative asthenopia; 3, retinal hyperesthesia; 4, photophobia with blepharospasm and interorbital neuralgia. The evacuation of the empyema and its cure were speedily followed by the disappearance of the eye symptoms.

Case 2.—Echondrosis of the triangular cartilage and chronic rhinitis. This case was attended with the following eye symptoms: 1, asthenopia; 2, pain in the eyeball; 3, injection of the eyes when used for close work; 4, blepharospasm; 5, contraction of the visual fields. These symptoms disappeared on removal of the growth.

Case 3.—Bony septum causing chorea, the following eye symptoms were present: 1, asthenopia; 2, subjective color sensations; 3, sneezing; 4, contraction of the visual fields. These symptoms disappeared on removal of the spine of the septum.

Case 4.—Advanced chronic atrophic rhinitis with middle turbinate hyperplasia. The following eye symptoms were present: 1, asthenopia; 2, lachrymation; 3, puffiness of the lids; 4, contraction of the visual fields. These symptoms were relieved by the treatment of the nasal condition.

Case 5.—Syphilitic ozena. The following eye symptoms were present: ("Transactions of the Intercollegiate Medical Congress of Australasia," 1889, Vol. ii, p. 779) 1, asthenopia; 2, lachrymation; 3, pericorneal injection on using the eyes; 4, contraction of the visual fields, which was temporarily removed by the use of amyl nitrate. These eye symptoms were ameliorated as the nose improved.

Case 6.—Polypi, nasal and naso-pharyngeal, with eye symptoms similar to those recorded.¹⁵

Polypi or vegetation, either in the superior or anterior nasal cavities, will oftentimes produce that peculiar deformity known as "frog face." When the nose becomes widened between the eyes and they protrude, the lids become granulated and drooped as seen in mouth breathers. Pressure on the upper part of the nasal duct

produces epiphora and sometimes conjunctivitis, which can only be cured by the removal of the obstruction and the restoration of the nose to its normal condition. Catarrhal conjunctivitis I find to be nothing but a reflex from nasal catarrh. Especially if the patient is of a catarrhal diathesis, a mere simple coryza of the nose will produce an inflammation of the mucous membrane of the inner surface of both eyelids, and will be reflected upon the ocular conjunctivæ. Abnormal developments of the ethmoid or sphenoid markedly affect the functions of the ocular muscles or the acuteness of vision. Over-development of the ethmoid, especially in the anterior portion, will sometimes produce complete stenosis of the upper part of the nasal duct, and there is epiphora from pressure; following this we get blennorrhæa of the lachrymal sac and possibly dacryocystitis. Abnormal development of the posterior portion of the ethmoid may produce widening of the inter-orbital space, displacement of the origin of the internal recti muscles, with high degrees of astigmatism and occasional divergent strabismus following. Over-development of the sphenoid may, by pressure of the optic nerve, produce permanent atrophy limitation of the field of vision and partial or complete color blindness. Hypertrophies, polypi or tumors in the superior nasal sinus may produce temporary blindness or high degrees of amblyopia, which are ameliorated or cured by the removal of the obstruction.

Dr. Edward Nettleship¹⁶, F.R.C.S., ophthalmic surgeon St. Thomas Hospital and Royal Ophthalmic Hospital, London, reports a case of a woman 50 years of age, who fell on her head (probably on her face). Vision failed about two days after the injury. She was unable to count her fingers with the right eye. Six days later hemorrhage of the nose set in. In twelve days the vision began to improve rapidly and fully recovered in four weeks.

The eye is rendered liable to infection from disease germs of every description that may find access through the lachrymal channel (Fig. 3), from the nose afflicted with diseases such as ozena, hydrorrhea, atrophic rhinitis, hypertrophic rhinitis with aqueous discharge, gonorrhæa, syphilis, diphtheria, measles or scarlatinal deposits, etc. The conjunctiva is a very delicate and sensitive membrane, and easily yields to an attack of morbid germs. These sometimes gain entrance to the eye by direct migration, but are frequently forced into the eye by blowing the nose, sneezing and not infrequently by the use of the Politzer air bag, or by Butler's inhaler. The cul-de-sac of the inferior turbinate body is the receptacle for the collection of material which is, or becomes decomposed, and finds its way or is forced into the lachrymal sac and to the conjunctiva many times followed by blennorrhæa, conjunctivitis, phlyctenular keratitis or ulcer of the cornea, which will not yield to treatment until the origin of the disease in the nasal cavity has been corrected. In specific diseases the lesions of the lachrymal organs including the canalicula, dacryoma in the nasal duct is usually found. Dacryocystalgia and purulent lachrymation may be caused by periostitis of syphilitic origin.

Dr. Bull¹⁷ says, "It is not common to meet with a purulent dacryocystitis, unless there is present disease of the periosteum or endosteum of the nasal duct, or carious disease of the bony canal of the lachrymal

bone. In some cases it is possible that the focus of the disease started in periostitis or endostitis of the nasal duct of constitutional syphilis, and spread to the mucous membrane lining the duct and sac, thus causing the dacryocystitis."

Syphilitic infections in the nose may be hereditary or acquired, yet they do similar mischief, very frequently causing obstruction by incrustations, yet there are other phases of lachrymal inflammation and obstruction, as described by Dr. David Harrower, who says, "obstruction of the duct may come from inflammation of the mucous membrane in the nose, simple chronic catarrh from a scrofulous or syphilitic origin. The swelling of the mucous membrane may extend by continuity to the mucous membrane of the duct. In the ordinary forms of ozena there is no swelling but cicatricial contraction of the nasal mucous membrane, which may lead to the constriction of the inferior orifice of the duct. Ulcers of the mucous membrane and polypi are also causes of obstruction of the nasal ori-

FIG. 3.—1, inferior turbinate bone; 2, nasal duct and valves; 3, middle turbinate body; 4, lachrymal sac; 5, lachrymal canaliculi and their orifices.

fices. The course is long, often extending years, if nothing is done for it; the secretion that at first was purulent becomes mucous and viscid, the mucous membrane may atrophy and the distended sac contain nothing but tears. The epiphora still remains. A person suffering from this chronic form may have an attack of acute inflammation suddenly develop. The skin over the sac becomes reddened and greatly swollen, the swelling often extending to the lids and to the conjunctiva, which may become chemotic. There is generally a great deal of pain, so much so that the patient is deprived of sleep. After a few days the skin at the apex shows a yellowish point and becomes perforated. The pus discharges and the swelling gradually disappears. Afterward pus followed by mucus, and later tears, are discharged. As long as this fistula remains open the patient is safe from another attack, but if it closes up a recurrence may ensue."¹⁸

In the spring and autumn of the year the attention of the practitioner is attracted by the number of chil-

¹⁶ London Ophthalmic Review, 1895, Vol. xiv.

¹⁷ Transactions of the Medical Society of the State of New York, 1882, p. 156.

¹⁸ Boston Medical and Surgical Journal, July 29, 1897.

dren who present themselves with corneal ulcers or phlyctenular troubles usually attended by nasal disorders. In such cases there is great congestion of the turbinates, profuse watery discharge, and formation of crusts in the nostrils, the sores extending down on the upper lip. The eye symptoms are persistent and attended by lachrymation and increasing photophobia, which resist local treatment until the nasal affection is cured.

Among the most common ocular troubles caused by diseased conditions of the nose, as of the lachrymal apparatus, although we have many cases of lachrymal trouble which are in no way influenced by conditions in the nose, yet are caused by the passage of germs from the eye through the canaliculi to the lachrymal sac or the nasal duct. We may have stenosis of the canaliculi situated at any place between the puncta and the opening into the lachrymal sac. We then have epiphora as an early symptom, followed sometimes by a contraction or atrophy of the lachrymal sac, but more frequently dilatation and blennorrhea. When the stenosis is situated in the nasal duct below the sac we have abnormal dilatation of the sac, and accumulation of secretion which soon becomes mucopurulent. In these cases, also, the prominent symptom is epiphora, and we may have, following this, conjunctivitis and dacrocystitis. Atrophic rhinitis with fetid discharge is most frequently the cause of lachrymal disturbances. The germs pass through the canal to the sac and remain there, the nidus of infection, until the disease is established. Empyema of the antrum of Highmore may be the cause of lachrymal disease, as the contents of the antrum may enter the nasal duct directly, or purulent secretion from the antrum may pass from the nose through the nasal duct to the sac.

I have now exhausted the literature on ocular disturbances from nasal disease, and I will venture to assert that more than one-third of external ocular diseases have their predisposing cause in the nasal cavities. Hence, I recommend a treatment plain and simple—remove the cause and you have cured the disease. If the disease is traceable directly to pathologic conditions existing in the nose, then it should receive proper treatment, in conjunction with the treatment of the ocular disturbance. If the epiphora is due to stenosis in the canaliculi, occlusion of the puncta, blepharitis, eversion of the puncta, etc., these conditions must be remedied. When the lachrymal sac is filled with acrid or mucopurulent discharge, it should be evacuated by means of firm pressure of the thumb or finger on the sac, pressing the retained secretion out through the puncta, after which the canal should be probed and washed out. In order to introduce the probe or the syringe nozzle the puncta must be enlarged. This may be done by introducing the canaliculus knife into the canaliculi to the nasal bone, the cutting edge being turned toward the eye, and by retracting the lid with the thumb, and drawing the knife out, make a small incision in the punctum, perpendicular to the palpebral fissure, large enough to insert the end of a syringe or Bowman's No. 8 sound. This operation maintains the integrity of the canaliculus, and the pressure of the lids on the eye tends to keep the edges of the wound apart and prevents adhesion and subsequent closure.

For washing the sac I have derived great benefit from the following solution:

R. Fl. ext. hydrastis.	3 iss	44 36
Zinci sulphat.	gr. iv	26
Aque destil	q.s. ad 3ii	59 14

To be injected with the lachrymal syringe every alternate day, the solution as hot as the patient is able to bear. If this or other conservative treatment fail, the obstruction can be relieved by surgical methods, which can be found in any of the ophthalmologic works of the present day.

In conclusion I will quote a few cases where I have successfully cured or relieved the eye symptoms by treating the nasal cavities and giving the eye little or no attention.

Case 1.—Mrs. G., aged 34, consulted me Oct. 15, 1894, on account of a spot on her eye, visible to herself (metamorphopsia). The eye was normal for refraction, the lids were red and slightly swollen. No muscular disturbance. The nose revealed extensive hypertrophy of both inferior turbinates with profuse mucoid discharge.

After the hypertrophies were reduced the lids cleared up and the spots that had been visible to her disappeared.

Case 2.—Mr. H., bookkeeper, age 30, consulted me September, 1895, for severe blennorrhea. Blurred vision and unable to continue work. Wore glasses for correction for $\frac{1}{4}$ D. Hypertrophic astigmatism, axis 90 in each eye. Examination of the nasal passages showed polypoid degeneration of the left inferior turbinate with two very large polypi, with pedicles attached in the middle meatus. On the right side were found two polypi and a large cartilaginous spur from the septum encroaching on the anterior third of the inferior turbinate. The cul-de-sac of the turbinate was filled with decomposed secretion. I removed all the obstructing difficulties of the nasal chambers, and three months after treatment the patient was discharged cured, and up to the present time has had no further return of the eye difficulties.

Case 3.—Mrs. S., age 26, consulted me November, 1895. An ulcer of the cornea of the left eye had been treated locally the preceding two months, with little or no result. Examination of the nose showed a long fissure on the right side of the septum and extensive posterior synechia. After surgical and medical interference in the nose the ulcer quickly yielded to treatment. Patient was discharged well.

Case 4.—Miss K., school girl, age 15, consulted me February, 1896, on account of epiphora and blurring of vision. On examination I found the vision O D and O S 20_{20} each, without astigmatism. In the nose I found large polypi in the middle meatus with long ridge on both sides of the septum. On the right side of the septum a fissured ridge badly irritated. The cul-de-sac of each inferior turbinate was filled with thick yellow secretion that could not be blown from the nose by the patient. I removed the polypi, thoroughly cauterized the turbinates and locally treated the irritated ridges. The patient soon recovered and has been able to renew her studies without further trouble with the eyes.

Case 5.—Miss F., age 14, March 10, 1896, complained of constant severe frontal headache, shooting pains in the eyes. Examination of the eyes showed them to be nearly emmetropic, vision in both eyes being 20_{15} , or a little better than normal, with perfect co-ordination of muscles. Upon examination of the nasal passages I found abundant post-nasal vegetation. Ten days after the removal of the adenoids patient was free from headaches and pain in the eyes, and has had no recurrence of the symptoms.

Case 6.—Mr. S., aged 33, occupation locomotive engineer. Was discharged from the service on account of color blindness. He was unable to distinguish red and green. There was no manifest lesion of the eye, fundus and refraction normal. Examination of the nose showed marked hypertrophy of the middle turbinates, and adhesion of the left middle turbinate and septum. I removed the left middle turbinate and cauterized the right, reducing it sufficiently. The color blindness began gradually to disappear, and in a period of four months the patient was able to successfully pass re-examination, and obtain his old position, which he now holds.

NOTE.—Cuts taken from the author's article entitled, "The Relation of Diseases of the Eye to Diseases of the Nose," in S. A. Bishop, on "Diseases of Nose, Throat and Ear."

Columbus Memorial Building, 103 State Street.

DISCUSSION.

Dr. HENRY GRADLE.—The statement that "about half of the external diseases of the eye have some connection with prior anomalies of the nose" is decidedly at variance with the

statistics I have gathered from my own experience. It is a very small proportion in which the nose plays any role at all. Two cases were quoted which seem to be open to serious doubt unless supported by much more detail than the brief synopsis given. One was ulcer of the cornea. I do not think it has ever been noticed by anyone before that ulcers of the cornea are in any way kept up by intranasal conditions. Indirectly an intranasal disease may lead to ulceration of the cornea, the infection may be conveyed through the fingers to the eyelids and conjunctival sac, or in some cases the infection spreads from the nose to the sac, leading to dacryocystitis. In either case the infection of the cornea having been started, the remote cause no longer has any influence over it. I have not seen anything suggested by actual experience which would show that nasal treatment would influence the course of corneal ulceration. Another instance was quoted, namely, color blindness having been relieved by intranasal treatment. Color blindness, as far as we can judge, is purely a psychic phenomenon. No one has demonstrated that there is any anomaly of the eye. It is not an acquired thing. Outside of disease of the optic nerve it is a psychic occurrence, and how that could be induced by intranasal anomalies has not been shown by the experience of anyone else. Undoubtedly there are quite a large number of important troubles of the eye which owe their origin to the nose. To those which he has mentioned I might add two varieties. One is the production of iritis in consequence of intranasal suppuration. My attention was called to it by Ziehme, who claimed to have seen it produced by antral suppuration. I have the records of four patients with recurrent attacks of iritis, most of the attacks being distinctly preceded by purulent rhinitis, limited to one side, and the corresponding side of the nose was structurally anomalous. There was either narrowness or deviation of the septum or some of the other conditions known to influence unfavorably the course of nasal suppuration. A second observation is that in some instances peripheral paralyses of the ocular muscles are due to intranasal conditions. I have in a previous paper referred to three successive cases that had come under my observation. I have seen two others since, where the paralysis occurred in one of the branches of the third nerve or was limited to the abducens, where the entire course and recovery characterized the trouble as peripheral. In all these patients the paralysis was preceded by acute suppuration in the side of the nose corresponding to the affected eye.

Dr. WILLIAM L. BALLENGER.—The essayist mentioned enlargements of the sphenoid and ethmoid bones, and I am not sure whether he meant simply hypertrophy of the bony tissue or a dilatation of the cells. But what I want to refer to is suppurative diseases of the accessory cavities. Let us take, for instance, empyema of the sphenoidal sinuses. If you will recall the anatomy of the parts, the position in which the optic nerve passes through the foramen and on to the globe of the eye, you will see that it passes over the sphenoidal sinus, and if there is an empyema of any considerable extent of the sinus the bony tissue becomes inflamed, softens, yields and is pressed upward, and as it presses upward the optic nerve is choked or compressed at its entrance into the foramen and we may have either a sudden, partial or complete blindness as a result. If we have empyema of the ethmoidal cells, pressure inward will produce disturbance of the muscles of the eye, and strabismus of one type or another may result. There is another condition related to suppurative disease of the ethmoidal cells which resembles dacryocystitis very much. A little lump appears upon the skin, but not in the same situation as in dacryocystitis, but above the inner canthus of the eye. This is due to a punching of the fluids or pus formation in the ethmoidal cells.

I have never seen a case of polypus of the inferior turbinated body reported. Zuckerkandl, in his great work, says he has never found polypus of the inferior turbinated body. I think it is generally accepted as a clinical fact that polypi do not occur here. I think that most of the inflammatory diseases of the conjunctiva and lachrymal apparatus, which the Doctor mentioned, would not necessarily be extensions from the nasal tract, but that the condition which caused the nasal disease also caused the eye disturbance. We do not understand very fully the nature of these inflammatory conditions, especially of the acute type. It is reasonable, however, to believe that the conditions have a common origin in something that has not been mentioned.

Dr. HAIGHT.—In answer to Dr. Gradle's remarks about the condition of the nose having nothing to do with a persistent ulcer of the cornea, I will say that I had, in my clinic at the Chicago Eye, Ear, Nose and Throat College, a boy 12 years old, who had a phlyctenular ulcer of the cornea lasting one year.

This boy had been treated in one of the post-graduate schools, in this city, nine months previous to the time he came to me, three months ago. He had much photophobia, profuse lachrymation, the upper lid was swollen so that the eye could not be opened by patient. There was watery discharge from the nose with post-nasal adenoids and enlarged tonsils. The adenoids and tonsils were removed and the nose treated in conjunction with the eye, and now the eye is entirely well with the exception of this resulting corneal opacity, which is clearing up. In connection with the case of color blindness I refer to the cases reported by Hamilton. While the case I reported of complete color blindness is the only one that came under my notice, still I have had other cases of contraction of the visual fields. What causes it I do not know. Dr. Ballenger misunderstood me. In my paper I spoke of polypoid degeneration of the inferior turbinated body, a condition which we frequently find.

TRAUMATIC CORNEAL ULCER: REPORT OF A CASE.

BY J. W. SHERER, M.D.

KANSAS CITY, MO.

Nov. 9, 1897, N. O., male, age 55, Swede laborer, applied at the clinic of Professor W. C. Tyree of the Kansas City Medical College, for dispensary treatment for an injury of the left eye.

Previous history.—No ocular disease had been experienced. Hard chancre was reported to have been contracted twenty years ago but none of the usual syphilitic sequelæ followed. General health has always been robust and an open air life led. Of late years there has been some inconvenience from advancing presbyopia, but the aid of glasses has not been sought.

Present condition.—November 6, while crushing stone with a hammer a fragment, presumably of stone, struck the left eyeball and caused intense pain. Rubbing and wiping the eye, an effort was made to continue the work. Next day the eye was still painful, became red and some discharge was observed. The symptoms increased in severity, causing sleeplessness, loss of appetite, perpetual shooting pains through the head, violent pain in the eyeball and painful photophobia.

Examination.—November 9, the fourth day of the disease: O. D. V. = 5/X. O. S. V. = 2/L. The vision secured with the right eye was practically normal for the light and card used; the exterior of this eye was also normal. Ocular tension normal. In the left eye there was severe bulbar conjunctivitis, most intense in the ciliary zone, and some injection of the blepharal conjunctiva. The lids were somewhat swollen, edematous and heavy. In the culs-de-sac some mucopus was found, but no microscopic examination was made. A shallow, central corneal ulcer was found which was foul and progressive. Its diameter was about three millimeters, its edges undermined and a narrow boundary of cloudiness marked the limit of cellular infiltration. The remainder of the cornea was clear. The iris was slightly injected, its motility sluggish. Pupil three millimeters. Ocular tension normal. Ophthalmoscopic examination of the right eye showed clear media, normal fundus and hypermetropia = +.50. In the left eye the fundus could not be readily seen but the reflex was normal and, obliquely, the media appeared clear and fundus normal.

With a + 16, the ulcer was seen to be an excavation with overhanging edges. It contained much debris, slough and pus. A diagnosis was made of infected corneal ulcer from traumatic contusion and laceration and treatment ordered as follows: Hot compresses four times daily twenty minutes at a time, the com-

presses to be kept constantly hot by plunging them in hot water; atropin sulphate 1 per cent. aqueous solution, 1 drop applied three times daily; free use of warm, sterile saturated solution of boric acid four times daily; a lump of 5 per cent. aristol ointment to be put in the eye each eve. The patient was requested to keep the eye bandaged and to report at the clinic three times a week.

November 11, patient reported improvement: "slept for first time in several days;" pain intermits and is lighter; pupil dilated to five millimeters only; swelling reduced. Treatment was continued and calomel laxative added. November 14, some chemosis present; pain is severe at times. Patient has not worked since second day of the injury. The ulcer is spreading downward slightly. With a small Bowman's lens scoop and free irrigation with boric acid solution, the ulcer was curetted. The edges were much undermined. Remembering the patient's suspicion of specific taint I put him on potassium iodid 0.65 gram three times daily.

The patient attended the clinic regularly and reported that all directions were carried out, but his home was badly ventilated and warmed and his assistance was poor. After curettement some improvement was observed; epithelium proliferating over the upper part of the ulcer. November 20 there was an acute exacerbation with development of much chemosis. The ulcer was again foul and curettement was repeated.

When next seen the patient reported much improvement under the treatment. A little later the favorable progress of the case was again interrupted. The denudation of corneal epithelium had extended inferiorly. The iris was discolored and remained undilated. Intense ocular and blepharal conjunctivitis was present with sufficient swelling of the membrane to cause some eversion of the lower lid. Some pus was precipitated in the anterior chamber. The lids were rubbed with silver nitrate, 1 per cent. solution, and the ulcer wiped out with a wisp of cotton dipped in the same solution. A little later this was repeated with improvement, the hypopyon being almost completely absorbed. Then another relapse occurred, the ulcer spreading downward and a heavy hypopyon forming. The whole lower segment of the cornea was cloudy and was apparently becoming infiltrated with pus. November 20 the patient came into the hospital and paracentesis was performed by Professor Tyce. With antiseptic precautions and under cocain, section was made with a Graefe knife through a very tough cornea, in its lower segment, and a mass of pus sufficient to fill one-third of the anterior chamber was discharged on the cheek. After irrigation and applying aseptic dressings the patient was sent to the ward. The complete antiphlogistic and antiseptic treatment was now executed by skilled hands.

At this juncture elixir of quinin, iron and strychnin was ordered in place of the iodid. The patient's strength was somewhat impaired by the suffering and nervous strain. He now suffered less and felt better, but soon the entire cornea rapidly became opaque, the lower half yellow and apparently infiltrated with pus. The chemosis again became great; the conjunctivitis was general and increased in severity and the swelling of the lids became worse. Within a few days the lower half of the cornea became markedly staphylococcal; the loss of the eye seemed at hand. The treatment was carefully continued with the addition of applications of silver nitrate, 1 per cent. solution,

to the blepharal conjunctiva every other day, and the exhibition of a calomel laxative, *pro re nata*.

The patient suffered but little from the time the paracentesis was done, and December 5 the general inflammatory condition of the eye and tutamina was perceptibly improved. Henceforth the improvement was continuous. The patient slept well, had a voracious appetite, little pain, and gained in weight. December 21, he was discharged from the hospital, all inflammation having subsided, with the cornea normal in contour and clear, except in the lower half, where a faint white, cloudy leucoma marked the area of the more severe keratitis. A few fine blood vessels had proliferated into this part of the cornea. At the time of writing, Jan. 7, 1898, O. S. V. = 3/50; the cornea is slightly faceted; the leucoma bids fair to clear up partly, either spontaneously or under stimulative treatment; the pupil is regular; the iris normal in motion and color; there seems to be no disturbance of the ocular metabolism, and the lids are healthy.

The points of interest are: 1, the extremely bad irritative symptoms caused by the movement of the lids over the wound and which were relieved by immobilization with a bandage; 2, the ulcer extended down in the line of gravitation of the pus in the anterior chamber and to the area of the cornea not covered by the lids; 3, the change in course of the disease with paracentesis, hospital and tonic treatment; 4, the utter failure of the antiseptic and antiphlogistic treatment at the patient's home under pernicious sanitary and hygienic environment and in unskilled hands; 5, the fortunate issue of the case from grave danger; 6, the disappearance of large quantities of pus from the anterior chamber by filtration through the mesh-work of the ligamentum pectinatum. 7, the certain loss of the eye had paracentesis not been done and had the patient not been kept in hospital.

310-11 New Ridge Building.

A REPORT OF A CASE OF ANOMALOUS THORACIC ANEURYSM.

Read before the Chicago Medical Society, Feb. 9, 1898.

BY G. W. JOHNSON, B.Sc., M.D.

Medical Superintendent of the Cook County Infirmary; Late Chief Male Physician to the Cook County Hospital for the Insane; Fellow of the American Academy of Medicine; Member of the American Medical Association, Chicago Medical Society, and the Mississippi Valley Medical Association.

CHICAGO, ILL.

Aneurysm of the aorta is not an uncommon occurrence in the experience of every physician, and from the group of symptoms found in text-books on practice and surgery is not especially difficult of diagnosis. That there are exceptional cases, however, in which a diagnosis is somewhat difficult, there is little doubt. Such a case is the one herein reported.

After having studied this case for some months and then being unable to make a satisfactory diagnosis, I presented the case to the Chicago Medical Society for diagnosis. A number of its most able clinicians became interested, and after considerable study and repeated examinations agreed upon a diagnosis of lymphosarcoma of the mediastinum, the tumor occupying the right thorax. The clinical and personal history, together with postmortem notes and the author's deductions, are here given in full:

Personal history.—W. D., aged 53 years, Irish, unmarried, is a plumber by occupation, venereal history negative, no history of alcoholism, typhoid fever, pneumonia or pleurisy. Has

enjoyed perfect health up to two and one-half years ago, family history negative.

Clinical history.—Two and one-half years ago patient began to complain of shortness of breath on exertion and of pain in the left chest. He was unable to lie upon the left side. Dyspnea and pain in left side of chest increased. He was admitted to St. Elizabeth's Hospital, Chicago, where he remained six months. No diagnosis was made. Was discharged and later admitted to the Cook County Hospital, Chicago, where he also remained for some months. While there he was presented by one of the professors on general practice to his class as a case of greatly thickened pleura. Was discharged from Cook County Hospital and sent to the county institutions at Dunning, Ill., where he remained until his death, without a correct diagnosis having been made.

Examination on admission to the Cook County Infirmary was as follows:

Inspection.—Body somewhat emaciated and anemic. Has lost sixty-five pounds. No difference in appearance of the two sides of the chest save that on the right side there is a turgescient condition of the superficial veins. Face somewhat edematous, with slight bilateral exophthalmus and chemosis. There is absence of respiratory expansion on entire right side of chest. Superficial epigastric veins and other superficial veins of right side of abdomen are enlarged to the size of a lead pencil and tortuous. There is respiratory dyspnea. Caput medusae is more marked when patient is in recumbent position.

Palpation.—Right axillary glands are slightly shotty. Behind inner third of right clavicle can be palpated one gland about one centimeter in diameter, other glands negative. External venous collateral circulation on right side is plainly palpable. There is complete immobilization of right side of chest. Vocal resonance is absent on entire right side of chest, except over a narrow strip posteriorly along right side of spine. There is no pulsus paradoxus, apex beat slightly down and backward. When one hand is placed flatly upon the chest wall and pressure made, a joggling sensation is imparted. With one hand on the posterior and the other on the anterior aspect of the chest and deep pressure made, the chest is found to be perfectly solid. Arteries are not sclerotic.

Percussion.—There is complete flatness over entire anterior and posterior aspects of right chest, save for a small zone along the right spine, which is dull, scapular region dull. Liver dullness extends from the sixth interspace to about five centimeters below the umbilicus. There is dullness over a small area of the sterno-clavicular region on the left side. Left lung is hyper-resonant. Area of cardiac dullness is practically normal.

Auscultation.—No respiratory excursion can be heard over right lung, either posteriorly or anteriorly, save a small zone along the spinal column and over scapular region, where the breath sounds are indistinct and feeble, vocal fremitus entirely absent. Over the central portion of the chest a loud systolic thrill can be heard, but it is not a bruit. There is no murmur in the heart. There is no arrhythmia and the pulse is full and strong. Thoracic paracentesis is negative. Patient complains of no pain now, save a dull pain in the lower lumbar region, and coughs but very little. Has no elevation of temperature. Has dyspnea on exertion. Sputa, urinalysis and sphygmographic tracings were negative.

Such was the patient's condition until within three weeks of his death, when he was suddenly seized with a sharp lancinating pain over the right sterno-clavicular region, which was quickly followed by an emphysematous condition of the integument over the seat of pain. This condition, however, soon gave way to an edematous condition which progressively spread bilaterally until the facial folds were entirely obliterated. The exophthalmus and chemosis became more marked and the conjunctiva congested and the face and ears edematous, almost to bursting. This condition was followed by a deep purple cyanosis. From the face and neck the edema extended over the trunk, then the upper limbs became involved, the right forearm being more edematous than the left. Then followed edema of the feet and legs with universal superficial capillary distension and congestion. Dysphagia and dyspnea became so distressing that food could not be taken, nor the recumbent posture maintained. The physical findings remained unchanged save for the increase of the area of dullness over the inner and upper portion of the left lung.

POSTMORTEM EXAMINATION.

Inspection.—Body, that of a man of medium size, moderately well nourished. There is pitting on pressure over entire body. Stellate superficial veins are quite prominent over thorax and arms, both posteriorly and anteriorly. Large veins show with considerable distinctness on right arm, and over the right side of anterior surface of the abdomen. Right superfi-

cial epigastric can be traced as far as ensiform cartilage. The veins on outer side of the thigh are more prominent than is usual. Edema of the arms is more apparent than that of the legs, and more apparent in the head and neck than in the arms. Measurements over muscular portions of both arms and legs show the right limbs to be larger than the left by from one-fourth to one-half inch. Right chest and right side of face do not measure more than left. Conjunctival vessels are injected, and the sclera is yellow. Ears are thick, tawny and dark purple.

Findings on incision.—Diaphragm extends on left side to fifth intercostal space, and on right side to the seventh rib. The free border of the liver, in the middle line, comes about one-half inch below the umbilicus, its right lobe reaches to the level of the iliac spine. Superior surface of liver reaches to the level of the ensiform cartilage. The heart reaches, on the left side, to the third interspace and one inch to the left of the sternum. Apex is not markedly displaced to left, but displaced downward. The left pleural cavity contains considerable fluid. The left lung is congested and edematous, otherwise normal. On the right side is a large mass occupying the mediastinum and extending into right side of chest and reaches to the left, as far as a line drawn perpendicularly through sterno-clavicular articulations. The right pleural cavity is entirely obliterated. The layers of the pleura are much thickened, measuring about one millimeter in thickness. They are closely bound together by adhesions that are very firm. The right lung is compressed from apex of chest to diaphragm, but pressed into a narrow zone by the side of the vertebral column. It is congested and edematous, but otherwise normal.

The heart shows no marked changes in myocardium. On the endocardium several patches of endocarditis appear, which is subendothelial and shows best on cusps of mitral valves. Mitral valves otherwise normal. Aortic orifice takes two fingertips. The valves are affected near their free surface; they are somewhat stiffened and show some atheroma where they spring from the endocardium. Right ventricle and tricuspid are normal, pulmonary valves normal. Left pulmonary artery appears normal. Right pulmonary artery shows some atheroma.

The aorta is the seat of a very large aneurysm which springs from the first portion of the arch. The aorta is atheromatous, but the atheroma is accompanied by but very little calcification. There is a small deposit of fibrin upon the surface of the aneurysmal wall, which is not very thick, and in some places markedly thin. It begins to broaden out within one-half inch of aortic valves, and from it are given off the vessels of the convexity. It extends to the beginning of the descending aorta. The atheroma extends down the descending aorta. The circumference of the descending aorta just beyond the aneurysm is six and one-half centimeters. The aneurysm presses upon the right pulmonary artery and on the descending vena cava. There is no fluid in the pericardial sac. Adhesions of pericardium are moderately firm, are uniform and universal. No calcareous masses are found in the pericardium.

The liver measures twenty-seven, by twenty, by fifteen, by five, by four centimeters, surface mottled, left lobe finely nodular. Gall bladder is of the usual size, but contains a number of small calculi and a small quantity of turbid biliary fluid. The mouth of the cystic duct is partially occluded with calculi; hepatic and common ducts are negative. Cut surface is somewhat uneven, centers of lobules depressed, the periphery elevated, showing congested atrophy.

The kidneys measure twelve, by seven, by five centimeters. Capsule is slightly adherent. Kidney is very much congested, surface granular. Cut section shows the cortex to the medullary portion, to be as one to three. Striation is distinct. There is an appearance of venous congestion and probably amyloid. Spleen is negative.

Recapitulation.—Having followed the clinical history to its end we have now the postmortem findings to aid us in accounting for some of the strange clinical phenomena and the error in diagnosis.

1. The earliest symptoms, namely, shortness of breath upon exertion, pain in the left chest, inability to lie upon the left side and the establishment of collateral circulation through the superficial epigastric veins, were due to loss of function of the right lung from the pressure of the aneurysm, producing unilateral pulmonary congestion. Pressure upon the vena azygos major would cause a stasis of the intercostal veins on the right side, the vena azygos minor, the upper left azygos vein, several esophageal, mediastinal and pericardial veins. The lumbar veins finally be-

came affected and the entire difficulty was partially relieved by the collateral circulation through the superficial epigastric system.

2. Pressure upon the inferior vena cava would produce a passive hyperemia of the liver and kidneys through the portal and renal veins.

3. As the aneurysm increased in size the function of the right lung became completely destroyed and the lung was made to occupy a narrow zone along the spine, which accounts for the dullness and feeble respiratory excursion over this area.

4. The later symptoms, namely, increased bilateral exophthalmus, increased dyspnea, dysphagia, bilateral chemosis, general edema, cyanosis, and the congested and distended superficial capillaries and the invasion of the upper lobe of the left lung, can be accounted for by the still further increase in size of the aneurysm, obstructing the return circulation from above by pressure upon the superior vena cava. The innominate and jugular veins, as well as the great vessels given off from the arch, being so universally and evenly involved, account for the absence of pulse phenomena.

In conclusion, from the foregoing we learn that many of the symptoms were misleading. The absence of the pulsus paradoxus and other pulse phenomena, and bruit, the extreme flatness of the right chest on percussion, the symmetry of the chest walls, the practical absence of pain and cough, the negative paracentesis and the entire absence of any auscultatory phenomena so common in aneurysm, together with the absence of such clinical phenomena as would usually be present in an aneurysm of such vast proportions, makes an error in diagnosis somewhat pardonable. However, from the clinical history and physical examination we have many points suggestive of a solid tumor of the chest. The absence of any pulse phenomena and the negative paracentesis, the unilateral collateral circulation, the enlargement of the glands, the absence of pain and cardiac disturbance, the solidity of the right chest and the deep shadow thrown by the skiagraph, would rather favor the diagnosis that was made.

That such a case should escape from two of our best hospitals and from such a large number of eminent clinicians without a correct diagnosis, is enough alone to brand it as an unusual case. But situated as the aneurysm was, together with its enormous size, and the pleura so much thickened, a great many of the symptoms were perverted.

DISCUSSION.

Dr. ROBERT H. BARCOCK—I examined this patient twice and made a probable diagnosis of lympho-sarcoma of the mediastinum and pleura. The case presented many of the signs of solid tumor; some of the signs of aortic aneurysm were present. The points which were of particular weight in favor of solid tumor were: 1, the insidious development of the disease; 2, the absence of fever; 3, evidences of unilateral pressure; 4, the phenomena on percussion, absolute flatness anteriorly from apex to base from the left sternal border to the middle of the right axillary region, the flatness being accompanied by a sense of great persistence; 5, there was some enlargement of the right half of the thorax, but it failed to present any of the irregular enlargement which is sometimes present in a case of solid tumor. The auscultatory findings were such as pointed to a solid tumor with entire absence of breath and voice sounds over area of flatness. Percussion and auscultation posteriorly were such as to plainly point to compression of the lung toward the back and spinal column without other involvement of the lung than that of pressure. There was against solid tumor, the entire absence of pain at the time I made the examination, although it was evident that a tumor occupied the right pleural cavity. There was also no marked debility, although the patient has lost weight. Evidently the

absence of pain was due to the fact that the tumor was not impinging upon the sensory nerves within the thoracic parietes. There were certain points in favor of aneurysm, and one was the jogging impulse, which was not very marked, but which could be perceived over the lower portion of the right thorax, and the transmission of the heart sounds at that point, in fact, more or less throughout the base of the right chest, and a murmur in the right infra-clavicular region. The pulses were apparently normal, although, at the first examination, in November, there was slight inequality in the two radials. The heart was pushed downward and outward, but evidently not greatly enlarged. These two things seemed to be rather against aneurysm, and the transmission of the sounds of the heart and the perception of a murmur in the infra-clavicular region were explained on the hypothesis of pressure from this solid tumor, and the transmission through the tumor of the heart's impulse. I am surprised that it did not occur to me that a tumor the size which this must have been, had it been solid, occupying so much space in the chest, should not have had an impulse imparted to it from the heart.

Dr. ARTHUR R. EDWARDS—I saw the case about a year ago, in the County Hospital, and at a still later time, when I examined him. There was the absence, at any time I examined the patient, of any murmurs, especially the absence of bruits, of any difference in the two radial pulses, or the exact quality of the two sphygmographic tracings when the patient was first examined. There was a finding at the second examination which was lacking at the first, namely, the development of a small, hard, presumably lymphatic node above the left clavicle or rather near the jugular, which was taken, in the absence of so many of the usual symptoms of aneurysm, and the presence of so many symptoms pointing toward the bronchial lymphatics as an evidence that the patient was suffering from a neoplasm rather than from simply a thickened pleura or an aneurysm. The lymphatic node was found about six weeks after the first examination. In cases falsely diagnosed previous to autopsy, and enormous aneurysms are found, it is because of clotting of the blood, or because of equal distention of the aneurysmal sac that no bruits are found. It will happen again that we will have murmurs in cases of mediastinal tumor, so that the murmur will make no difference to us in the diagnosis.

Practically all that can be said on the subject has been recapitulated by Fraenkel, that "aneurysms may produce such changes in the lung or respiratory apparatus that the aneurysm itself may be overlooked, and secondary changes may be the main findings clinically. The pleuritic effusion may cover up the aneurysm, or, after tension has disappeared, there may be a callosity of the pleura very much like a small tumor. By the pressure of the aneurysm upon a bronchus the lungs become impermeable to air, and finally there is enormous induration because of the atelectasis of the lung and disturbed circulation of the lung substance."

A case was seen, some three years ago, in the County Hospital in which almost the same symptoms were observed as in this, except the lymphatic glands pointed to mediastinal tumor. There was absolutely no murmur, and no inequality of the radial arteries and radial tracings, and yet a diagnosis of aneurysm was made and confirmed simply because of the slow progress of the case and the presence of a syphilitic history.

CUTANEOUS ADMINISTRATION OF SALICYLATES IN RHEUMATISM, GOUT, ETC.

BY GILBERT I. CULLEN, M.D.

CINCINNATI, OHIO.

Dr. Edmund L. Gross of Paris, in a recently published brochure, presents several new ideas. He says that though the various affections classed under gouty or rheumatic often differ widely as to their manifestations, they incontestably possess numerous traits in common. Even though we may admit that gout and rheumatism are distinctly separate diseases we can not deny their close original relationship, both affections spring from the same soil, the arthritic temperament. That which above all else seems to prove their lineage is the common property which they possess of being unamenable to the salicylic medications, though in different degrees. The benefits derived from the use of the salicylates in rheumatism are universally acknowledged and yet much difference of opinion

exists as to their real value. Some look upon them in the light of simple palliatives while others, and perhaps the most authorized, consider them real specifics. I firmly believe with Lecorde that salicylic acid is as much a specific in rheumatism as mercury is in syphilis. If the salicylate of soda is universally administered in all cases of rheumatism, it is less generally known that gout is greatly benefited by the same drug, especially when combined with colchicin. The great disadvantage heretofore met with in the exhibition of the salicylates has been their irritating influence on the digestive tract, which often excludes the advisability of their administration. These untoward results may be greatly attenuated, if not entirely avoided, by using the natural salicylates derived from the oil of gaultheria, betula lenta and other plants. This pure salicylate of methyl, as proved by the experiments of Professor Charteris of Glasgow, offers none of the inconvenience of the synthetic salicylate of soda and may be administered by the mouth in much smaller though equally effective doses.

There is another method of administration, however, rapidly coming into vogue in all hospitals. We are taught by the interesting researches of Professor Combemale of Lille, and also of Professor Sigalas of Bordeaux that salicylate of soda, when dissolved in some oily vehicle, is rapidly absorbed by the skin, and in five minutes may be detected in the urine. This medication is now extensively used in the hospitals of Paris. Professor Déjerine has a favorite formula which he prescribes for all his rheumatic patients: it is the following:

R	Acidi salicylici	Gm.	10
	Alcoholis	Gm.	50
	Ol. ricini	Gm.	100 M.

This external application should be used in the following manner: A tablespoonful is poured into the palm of the hand and rubbed into the affected part for a few minutes; the part is then covered with oiled silk or rubber and again enveloped in several thicknesses of flannel or cotton.

The effect of this medication is very marked and the pain rapidly subsides. This is due to the fact that salicylic acid is one of the best of anodynes; it exerts this action over all pains even though they be not of a gouty or rheumatic nature. Professor Panas of Paris has sometimes used salicylate of soda as a substitute for morphia. In rheumatism there is, in addition to this anesthetic influence, a true specific action, probably due to the antiseptic properties of the drug.

There are many advantages in the cutaneous administration, of which the most important, perhaps, is the relief afforded to the digestive tract, but there is also the efficacy of a method which consists in applying a drug directly to the part affected, so that the greatest quantity is absorbed where it is most needed. This does not exclude the administration per os, but it it should be given in such minute doses that no evil effects will be felt.

I have been speaking of salicylic acid and salicylate of soda and yet I have long since abandoned this form of salicylate. I never use any but the pure methyl salicylate, as advised by Dujardin-Beaumetz, Sireday and others and find the natural product far superior to the artificial drug, both internally and externally. The above liniment used by Déjerine is far more effective if oil of wintergreen is substituted for the salicylate of soda.

It is remarkable what a wide application such a liniment has; all pains, muscular or articular, are greatly benefited. As a resolutive liniment it has no equal. I recently treated a severe case of phlebitis of the saphenic vein accompanied by a considerable tumefaction running the whole length of the thigh. The classic treatment, rest and calming applications, did absolutely no good, after two weeks of rest in bed. I tried the salicylic liniment and used the French formula known as betul-ol. After a few applications the case improved, the pain disappeared and the swelling melted away very rapidly. In fifteen days after I had used the liniment for the first time the patient was almost entirely well.

In lumbago no application is as effective as the methyl-salicylate liniment, vigorously rubbed in the part, then covered with oiled silk and several thicknesses of cotton, being held in place by a flannel band. I prefer the betul-ol formula because it contains a natural methyl salicylate dissolved in oleic acid, which traverses the pores of the skin with the greatest ease.

THE EXPENDITURE OF ELECTRIC ENERGY.

Read at the Seventh Annual Meeting of the American Electro-Therapeutic Association, Harrisburg, Pa., Sept. 21-23, 1897.

BY MARGARET A. CLEAVES, M.D.

Director of the New York Electro-Therapeutic Clinic, Laboratory and Dispensary; Late Instructor in Electro-Therapeutics, New York Post-Graduate Medical School; Fellow of the American Electro-Therapeutic Association; Member Société Française d'Electrothérapie; Fellow of the New York Academy of Medicine; Member of the Medical Society of the County of New York; Member of the American Medical Association; Member of the New York Electrical Society.
NEW YORK, N. Y.

To the physician, whose daily electro-therapeutic work is carried on with a voltmeter as well as a milli-ampere meter in circuit, the fundamental characteristic of electricity—pressure—becomes immediately a self-evident fact. While this may be a perfectly familiar truth in the abstract, it is impossible to have that clear perception of it which arises from the use of the means for its actual demonstration and measurement. So long as there is recognized in electro-therapeutic work only the rate of flow in milliamperes, it is not possible to have an intelligent conception of the force by means of which we make electricity available, or of the laws governing its action.

Whenever connections are made between the source of an E. M. F. or pressure (whether provided by chemic generators or dynamos) and the voltmeter, the needle swings to its place with certainty and precision, demonstrating the existence at the terminals of a pressure (potential difference) whose expenditure is capable of producing definite results, just so surely in electro-therapeutic work, as in electric engineering. Without a voltmeter there is no means of accurately determining the existence of this pressure. Who has not completed the conducting circuit to find that when the "current is turned on" the milliamper meter needle does not move at all, or else after a moment swings abruptly forward because resistance interposed in the circuit, perhaps due to an imperfect contact, has been suddenly overcome? There is thus caused a sudden expenditure of energy in the patient's circuit, resulting in severe shock and physiologic harm. With a means of determining the presence of

this initial pressure and whether it maintains itself steadily or whether, from imperfect contact, a variable E. M. F. exists, indicated by the fluctuations of the voltmeter needle, all question of trouble, in so far as the pressure at the terminals is concerned, can be eliminated before the conducting circuit is completed. If when the latter is accomplished and resistance placed in the circuit there should not promptly be established a rate of flow as indicated by the milliamperemeter, the operator does not need to go back of his conducting circuit, *i. e.*, conducting cord, electrodes and patient, to determine the whereabouts and nature of the trouble.

The above diagram represents the manner of connecting the voltmeter in circuit so as to secure the necessary readings.

The connections of the voltmeter are across the electrodes, eliminating thereby the resistance of the controlling device with which our batteries and adapters are usually provided.

When connections are made for work there are certain facts to be observed from which certain others are to be calculated, in order that we may have some definite idea of the force with which we are dealing, of the expenditure of energy and of the resistance of the obstructions in the conducting circuit.

This brings us to the two grand divisions of our charts, namely observed and calculated facts.

Under the head of observed facts, we have first, the source at the terminals, or potential force in volts.

As will be seen from an examination of the charts, this varies greatly. The work was done with the Kenelly adapter, and the varying pressure obtained by shunting the excess of voltage through the lamps provided for that purpose; and as in some instances, the adapter was connected directly with the Edison incandescent or direct current circuit and in others with a motor dynamo, the result is a pressure at terminals of considerable variation, say from 15 to 120 volts.

With the direct current from the Edison incandescent circuit the potential force, pressure or E. M. F., varied at the terminals from 115 to 120 volts. With the motor dynamo, converting a Thomson-Houston alternating current at 101 volts into a direct current, the E. M. F. at the terminals varied from 40 to 60 volts. Whatever our equipment, with the existence of this potential force in volts, demonstrated beyond question, its expenditure at once becomes a matter of actual observation.

An E. M. F. is often likened to the pressure or head of a body of water, a reservoir for instance. As we have seen, the E. M. F. is the initial thing, and relates

to that potential force which establishes the difference of potential. Nor is it possible to have an electric current without a difference of potential. As water flows from a higher to a lower level, so the electric current is assumed to flow from a higher to a lower potential. In order to secure and maintain a potential difference it is necessary to connect the initial pressure with a conducting path or circuit in which we wish to do work. And wherever we wish to do useful work there must be placed in the conducting circuit an obstruction or resistance. This we have in the person of the patient forming a part of our conducting circuit, as well as in the milliamperemeter, conducting cords and electrodes. In overcoming this resistance or obstruction in our path a part or perhaps the whole of the initial pressure may be expended. "At every point in such a path, or more accurately, between the two points, no matter how large nor how easy the path may be, some fraction of the total pressure has been expended in exact proportion to the opposition it met, or in other words to the resistance which it encountered."¹ Were it not for resistance in a circuit, no work would be done. In the path of the pressure expended on the tissues of the body the same law applies as in electric engineering. The voltmeter needle indicates promptly and definitely the standard of pressure which can be relied upon to initiate and maintain this expenditure of energy, and thus we are able to record the second of our observed facts, *viz.*, the available potential difference or available E. M. F. This difference of potential falls in value as the current flow increases, and if we will think of that current flow which we call milliamperes, or fractions of an ampere, as the expenditure of volts per ohm of resistance, just as the expenditure of a certain muscular force, moving a definite weight, results in a certain rate of work which we may call foot pounds, the fall in value of the potential difference as the current flow increases will be readily appreciated. In the latter instance the expenditure of muscular power leaves less for further efforts (a potential difference, or a difference of potential). In the same manner using up a variable proportion of the E. M. F. in overcoming a variable resistance, gives a variable remaining difference of potential.

Before the resistances of the patient and contacts are placed in circuit, the E. M. F. of the dynamo current (for instance) as registered by the voltmeter, will be, say fifty-two volts. These fifty-two volts do not represent the entire output of the dynamo, as there is a little loss in the voltage due to the resistance of the armature or what is known as the "internal drop," and also an additional loss in the conducting circuit as represented by the insulated wires running from the dynamo to the room in which the adapter is placed. Now, the fifty-two volts, which were shown by the voltmeter, when the dynamo was set in motion, is the initial pressure, E. M. F. or, as per our charts, the source at the terminals. As the resistance is overcome there is a current flow as the case may be, of .010, .015 or .020 of an ampere. When this rate of flow is established it is found by observation that the voltmeter registers, say forty-six volts.

The amperes, whatever their number, give the rate of expenditure of volts per ohm independent of time, or the rate of flow. The forty-six volts is the actual working pressure or E. M. F., *i. e.*, the available poten-

¹ Current Distribution. By W. J. Jenks, E. E. Transactions American Electro-Therapeutic Association, 1894.

tial difference at the electrodes (volts), the rest having been consumed in overcoming the resistance of the conducting circuit, *i. e.*, the milliammeter, conducting cords, electrodes and patient.

The six volts used in overcoming the resistance of the circuit is called the "drop." A part of this pressure has been expended on the conducting circuit other than the patient and is known as "conductor drop" and a part on the patient in doing "work." If there is added to these the potential difference, forty-six volts, or forty-six plus six, we have the total E. M. F. of the circuit external to the dynamo. The resistance of the milliammeter as well as conducting cords and electrodes is practically negligible however. On expending a part or the whole of this initial pressure in overcoming the resistance of our circuit, and in doing useful work, a current is brought into existence, as we have seen, which our milliammeter needle promptly and accurately registers, and which we record under the head of milliamperes as the third of our observed facts. This expresses the rate of expending volts per ohm of resistance, or in medical applications of millivolts per ohm, and is usually the only measurement recorded by the electro-therapist. Given then a working E. M. F. or available potential difference, and the rate of flow in volts per ohm of resistance, it becomes only a matter of calculation to determine the resistance of our conducting circuit, for the E. M. F. divided by the C. S. gives us the resistance in its unit of measurement or ohms.

This brings us to the second broad division of our charts, where we find that there are certain facts, which instead of being observed are obtained by means of calculation, and the first of these is the body and contact resistance in ohms. This is a step on our way, for the resistance of the human body in health and disease promises to be a matter of great importance to the physician.

It has been suggested by a well-known physicist "that an accurate knowledge of the resistance from point to point of an average human body might assist occasionally in the diagnosis of disease, and the comparison with the resistance of a corpse might have useful results to show." But as yet, however, our conception of the expenditure of electric energy is very inadequate, for our only measurement thus far simply expresses the rate of flow in M. A., and conveys no comprehension of the rate at which we are doing work in the tissues. This can be only determined when the total expenditure of potential between the two given points in the electric circuit is found and multiplied by the rate of such expenditure in each unit of resistance between the same two points; or in other words, when the volts are multiplied by the milliamperes we secure a product in volt-amperes, or better, in the unit of electric power, watts. By this process the rate at which we are doing work or expending energy in the treatment of a given condition, whether a uterine fibroid, pelvic exudate or a wasted muscle, wherever or whatever it may be, is determined. But it is desirable that we should know not only the rate at which we are doing work but the total amount of work done. To secure this aggregate, it is necessary to add still another factor. By recording the observed time of an application (see fourth division of observed facts of our charts, "time in seconds"), it becomes at once an easy matter to obtain the total energy expended in the tissues; for the rate of work, the volt-amperes or

watts multiplied by the time in seconds will give us the total amount of work done, the volt-ampere-seconds or *joules*. By referring to the third division of our second broad division we find recorded the total amount of work done (energy expended) in the units of work or joules. This may be in heat developed, as in cauterization applications; it may be in mechanical work done, as with alternating currents, or it may be in chemical action as in the applications of the direct current.

The rate of work, as well as total amount of work done, can be calculated in fractions of a horse power or foot pounds, if it will convey any clearer conception to our minds of the rate of expending energy or the total amount of energy expended within the tissues. But the sooner we come to think in electric units, however, with a definite idea of their meaning, the sooner will we do our work understandingly and advance the cause of scientific electro-therapeutics.

Perhaps it may not be undesirable before further considering the expenditure of electric energy in the human body, to briefly recapitulate here the definitions of the less frequently used units of measurements.

The joule is the international unit of work, and is nearly equal to .7381 foot pounds at the latitude of Washington.

The watt is the international unit of activity or power, or of the rate of working per second of time, and is an activity of one joule per second. That is, the force that will raise one pound at the latitude of Washington through the distance of .7381 foot in a second, expends work at the rate of one watt, or one joule per second.

The horse power represents an activity of 550 foot pounds per second at Greenwich or 746 watts, so that one horse power equals 0.746 kilo-watts, that is one kilo-watt equals 1.34 horse power.

It is important that there should be clearly understood the difference between work or energy expended (joules) and activity or power (watts).

Work, *i. e.*, joules, is a measure of the expenditure of energy, and is equal to the product of a force and the distance of time through which that force acts.

Activity is the rate of expending energy (watts) or doing work, and is found, or at least averaged, by dividing the work done in a circuit, or a portion of a circuit, by the time occupied in doing it.

When a weight of one pound is raised through one foot, whether it be raised in a minute, or in a second, the same amount of work is done, but in the latter case, the rate at which the work is done or energy is expended is sixty times greater than in the former. Suppose a mechanical energy that is capable of raising 33,000 pounds 1 foot in 1 minute. This equals one horse power. It will be readily appreciated that here a tremendous force is exerted, and one which is capable of producing a serious injury to anything that may come in its path; but suppose that 33,000 pounds to be raised 1 foot in a period of time from 5 to 10 minutes, one can readily appreciate that this immense force could be applied without tending to cause mechanical injury. Thus we see that it makes a very great difference as to the rate at which the work is done. In the former instance just as much work was done or energy expended as in the latter, but at a very different rate. Or again, take the lightning flash, or an explosion of dynamite. If the same number of heat units which are in these cases exploded, perhaps

in one millionth of a second, could be so retarded in expenditure as to cover one second or one minute, no destructive action would be apparent.

When lightning strikes a forest tree, the inconceivable rapidity of expending a given number of heat units allows no time for gentle radiation, but instantly turns to steam the moisture in the tree trunk and beneath the bark, which then occupies 1600 times the space which it did in the form of water, and the steam pressure becomes so terrific that nothing can withstand its outwardly expended energy. With these examples it is easy to appreciate why there should be known not only the total energy expended, but the rate at which that energy is expended.

Suppose a pressure or E. M. F. of 120 volts, and a current flow of 50 milliamperes to be expended within the tissues, uniformly, during the period of 1 second of time, or during any other period; the rate of expending energy would be $120 \times .050$ volt-amperes or 6 watts, and the total amount of energy expended in 1 second would be $120 \times .050 \times 1$ volt-ampere-seconds or 6 joules; such an expenditure of energy would have a tendency to disruptive action upon the tissues, and would be capable of causing great injury to them, while a lesser E. M. F., say 30 volts, a lesser rate of flow, say 25 milliamperes, extending over a period of 8 seconds, or again a pressure of 30 volts, but a still smaller rate of flow, say $12\frac{1}{2}$ milliamperes, extending over a period of 16 seconds, would cause as great an expenditure of total energy, but one that would result in no disruptive action upon the tissues. On the contrary, the latter would prove an expenditure of energy which would not be felt in an appreciable sense, would cause no injury, and would tend only to the furtherance of physiologic action of the part to which it was applied.

To summarize: Force is a cause of change. Energy is the power of doing work. Work is energy expended (joules or volt-ampere-seconds). E. M. F. is measurable by the total potential difference at the electrodes (volts). Current is the rate of expenditure of volts per ohm (amperes) independent of time. Power is the rate of expenditure of energy not in time but in the total ohms, independent of time (watts).

It is essential then to know not only the rate of flow, as indicated by the number of milliamperes, but also the working E. M. F. (that is the available potential difference at the electrodes) and the time of a given treatment, so as to be able to calculate the rate of the expenditure of energy and the total energy expended, not for the satisfaction of making such a calculation simply, but because, to promote processes by means of which it is possible to restore healthful function, the same total energy should be expended slowly, so as to give the tissues themselves, to their molecules and atoms, an opportunity to adjust themselves to the influence at work.

"We must bear in mind here that it is not the electricity itself which is directly effective, but that by its means there is conveyed to the proper point a potent energy so flexible, so obedient to known laws as to result in a transformation to heat and chemic action, or some other manifestation, *i.e.*, the energy peculiar to vital cells. And that energy should be expended at such a rate as to encourage this action, not militate against it, as would be the case in a sudden expenditure of the same amount."³ And that rate of expending

energy or volt-amperes must be obtained by the expenditure of only such a pressure as is necessary to procure the requisite current flow through the obstructions placed in the path, or the resistance of the conducting circuit. We are thoroughly cognizant of the inadvisability of using the same muscular force in handling a fragile microscope cover glass as in the iron plate covering the manhole of a sewer. We know at once that the result would be disastrous to the cover glass. On the other hand, we know equally well that the muscular force necessary to lift the cover glass will have no effect whatever upon the iron plate.

Physical laws are the same, no matter what the agency used. There is therefore every reason why our apparatus, whether used with chemic generators or dynamos, should be so constructed that the pressure in volts can be carefully graduated from the fraction of a volt up to the full E. M. F. of which the generator is capable.

The blow that will cause the death of an eagle will not only take the life of a tiny humming bird, but shatter it to atoms as well, while the power necessary to cause the death of the latter may have no effect on the former. Just so must our volt-amperes be regulated to the work done. The acute neuritis, as well as the acute and subacute pelvic inflammations, for instance, require the minimum rate of expenditure in volt-amperes and it is not only the milliamperes we must look to, but the volts as well. We may use 20×5 volt-amperes or 5×20 voltamperes in the treatment of a given condition. The rate of expenditure, or watts, is the same in both instances, but the action upon the pathologic condition must be different. In the one instance the pressure in volts is in excess of that needed with which to do the work and expended along our conducting path and can only result in physiologic harm to the tissues involved.

In the conditions which we have just indicated nothing is to be gained by carrying our applications to the point of pain. We must remember that we are expending an energy within the tissues which produces a silent chemic change, that our purpose is to expend that energy in such a way as to exercise a directive influence upon the molecules and atoms, not to cause any disruptive action of which pain might be a manifestation, and that to gain our end it is not only wiser but necessary to expend fewer volts per ohm of resistance (or fewer milliamperes) for a longer time. By increasing our time limit the volt-ampere-seconds or the joules are increased, but at no time is the rate of expenditure in watts, or fraction of a horse-power, sufficiently great as to cause pain or destructive action. In the treatment of fibroid tumors or exudates, on the other hand, greater pressure is required, in order to overcome the resistance of the denser structures in the conducting path, so as to secure necessary current flow.

In percutaneous applications the proportion of the volts and amperes must vary considerably from their proportion in mucous membrane contacts. In the former considerable pressure is expended to overcome the resistance with a minimum of current flow; in the latter, because of diminished resistance, less pressure is needed to secure the necessary rate of flow. In both instances, however, there may be the same rate of work or watts.

In our electro-therapeutic applications, however, there must be considered not only the expenditure of watts, but the path of its expenditure. This brings

³ "Current Distribution," by W. J. Jenks, E. E. Transactions American Electro-Therapeutic Association, 1894

Mrs. J. T., age 33; occupation, domestic duties; condition, married. Diagnosis: Metritis and endometritis with cystic degeneration of cervix. Treatment: Vaginal hydro-electric douche, three quarts 3 per cent. saline solution, temperature 100 F. negative; indifferent electrode 36 square inches in area to abdomen; intra-uterine silver electrolysis; indifferent electrode 36 square inches in area to abdomen negative; cupric puncture to cystic cervix, indifferent electrode 36 square inches in area to abdomen negative.

us to a consideration of the density or degree of concentration of the current. The path of the greatest current density or expenditure of watts may or may not be in the most direct path between the electrodes. This will depend upon the pathology under consideration and the habit of the patient, as we shall see later on. However, as a rule we should expect that the densest current, in an intra-uterine application in endometritis, for instance, would be the most direct. Increasing the distance traversed by the current tends to an increase of the resistance and as the expenditure is always in the lines of least resistance the tendency would naturally be in the lines directly between the two electrodes. But in such an application, as usually carried out, the greatest expenditure is on the anterior surface of the uterine canal, because of the direct path between that and the abdominal wall occupied by the surface contact or indifferent electrode. The expenditure on the posterior wall would thus be reduced to a minimum, because this would not be the conducting path owing to the greater distance to be traversed and hence greater resistance. To our failure to expend energy upon the uterine mucosa in its entirety must be

attributed our failures in relieving existing pathology. In consequence of this law it will be better in such conditions to use both abdominal and lumbo-sacral surface contacts with a bifurcated cord, in order to insure as equal an expenditure of energy throughout the uterine mucous membrane as the character of the structures and their resistance will permit. It is not the agent which we use that is at fault, but it is our failure to adapt the means to the end. Electrodes are not constructed so as to produce complete contact, and our technique is at fault. It is not sufficient that energy be expended in the tissues, it must be expended in such a manner as to influence directly the diseased structures. And where this is a localized condition, as in a typical endometritis, at that point must be exhibited the greatest expenditure of watts.

For instance, in a vaginal hydro-electric douche with abdominal surface contact, a working E. M. F. of forty volts and a current flow of twenty milliamperes, the energy expended in one second of time would be eight joules, but that energy would be expended throughout all the tissues of the pelvis. On the contrary, in the intra-uterine treatment of an intramural

fibroid, anterior, with abdominal surface contact, given the same available potential difference, the same current flow, there would still be in one second of time an expenditure of eight joules, but that energy would be expended or work done at the site of the internal electrode, *i. e.*, on the anterior uterine mucous membrane, and secondarily upon that portion of the intramural growth directly adjacent, instead of being distributed, as in the former instance, over considerable areas of tissue.

These examples are multiplied in the charts which accompany this paper, and in some instances, attention is called to them under the head of "Remarks."

In a hydro-electric application, whether vaginal, intestinal, vesical or nasal, the idea is to distribute the current as thoroughly as possible throughout the diseased tissues. We do not desire a localized application or expenditure of watts in a limited path, as for instance in an endometritis, a urethral stricture or hypertrophied turbinated body, but wish to distribute the expenditure through large areas so as to bring the entire pathologic condition under its influence. In a pelvis filled with exudates, a foot or a hand the subject of a sprain, a rheumatism of a leg or arm, an articulation immobilized by exudative material or sheaths of tendons bound down by the products of inflammatory action, our aim must be current distribution, and to that end we utilize either electrodes of large square inch area, or warm saline solutions with which the part is filled or in which it is immersed. The saline solution becomes the electrode carrying the current to all parts of the diseased structures.

We are not to think of the current as flowing in direct lines through the region between the two electrodes, but as seeking its way from its positive to its negative pole by paths which are often devious, those of best conduction. For instance, in a vaginal or vesical hydro-electric, or intra-uterine treatment of a patient whose abdominal wall is thickly covered with fat, there is great divergence of the direction of the lines of current, because the fat itself is practically a non-conductor and only has conductivity by reason of the few blood vessels running through it. The energy is expended therefore, along the paths of least resistance, through the interstices, as it were, the blood because of its fluidity and salinity affording good conduction.

If the patient be of a lean muscular habit, there will be less divergence of the lines of the current, and greater current density, *i. e.*, greater expenditure of watts even with the same square inch area of electrode; because the conducting medium being good, and affording practically the same resistance in all parts the lines of the current will be more direct; there will be no seeking of by paths, but a straightforward push throughout the interpolar region.

The greatest expenditure of energy is always at the point of greatest resistance, but if we wish to expend the energy at such a point, then we must so adapt our electrodes to the condition to be treated that there may be offered little or no opportunity for any divergence of current flow, but a distinct localization within the prescribed limit. For instance, in epilation there must be had a minute, almost microscopic localization of the current. A tiny steel needle is inserted into the hair follicle and attached to the negative pole. Action upon the skin is to be avoided. The indifferent electrode is placed conveniently near at

hand so that as little resistance as possible shall be interposed. In this application our desire is to avoid just as much as possible current distribution. Nothing is to be gained by it, but much to be lost. If the indifferent electrode be large (from three to six square inch area is abundantly large) there is a greater diffusion at that point and greater current density at the needle than is expedient. There is a convergence of the lines of current flow from the indifferent electrode to the tiny needle electrode placed within the hair follicle. At the latter the cathions are concentrated; at the former the anions are distributed over its surface. At the site of the internal electrode there is current density, at the indifferent electrode current distribution. The same conditions exist in any intra-uterine or intra-nasal application. In the destruction of a growth, as a fibroid tumor or a mole, current density is necessary at the site of the intra-uterine electrode or of the needle in the mole.

Whether current distribution or current density are required at the active electrode, depends upon the pathology underlying the condition you wish to treat. There are factors which must enter into every application and they are dependent upon and influenced by the resistance in the path of the current.

I have not thought it best at this time to draw any deductions from the resistances obtained in the various pathologic conditions or in the different applications of the current embodied in the accompanying charts. Under the head of "Remarks" on the charts will be found statements as to the difference in resistance in the hydro-electric applications to the mucous cavities and intra-uterine applications. In the former instance the cavity is filled with warm salt water, a good electrolyte with comparatively low resistance, and more than that the current as we have seen finds the way of least resistance. In the intra-uterine applications, however, the path is through the denser structure of the uterus itself, which must of necessity have greater resistance, and in addition these applications are nearly all of metallic electrolysis, where the formation of the oxid, and its transference increases the resistance of the conducting circuit. In the cupric and zinc punctures to the cervix in a series of cases, a difference in resistance will be noted between those made into the cystic portions of the cervix and those made in the denser portions, especially in the cases of cervical fibroids. A difference will also be noted in the resistance of the conducting path in vaginal hydro-electric and intestinal hydro-electric douches, while considerable increase may be noted in the percutaneous applications over those with one mucous membrane contact. The comparisons must be made in those instances where the available potential difference or working E. M. F. was practically the same. A high pressure was used in some instances where its use is considered undesirable, and where with the present means at command of limiting the source at the terminals, it would not again be used in similar conditions.

I call your attention to the chart, which gives in recognized units of measurements the same facts for alternating currents of both the symmetrical and dissymmetrical types, or the sinusoidal, and faradic, as for the constant currents. They are few in number, as the volt and milliamperere meters were put in my hands but a week since, but have been very instructive, and through the agency of such instruments of precision, the therapeutic applications of these cur-

rents will soon be reduced to the same exactitude as those of the constant current.

In these observations the readings are given in virtual or effective milliamperes and also the working E. M. F. in volts employed in sending this current through the body. From the pressure in volts and the current flow in milliamperes thus obtained and time observed, calculations have been made giving the resistance, the rate of expended energy in watts and the energy expended in joules. Under the head of "Remarks" will be found a statement giving the equivalent as to coil, character of interruptions and number of turns of wire with the faradic and the frequency of the sinoidal.

TERMINAL BINDING POSTS OF COIL OR ALTERNATOR.

The above diagram represents the manner of connecting these instruments both with the coil and the alternator.

These instruments have not been in my hands a sufficient length of time to make extended observations. I feel that this addition to our equipment marks a new era and one that can not fail to be fruitful in scientific results. Not until work was done in the manner indicated by the charts did there come the clear and definite conception of its nature now possessed. Instruments of precision have done much toward the establishment of scientific methods, and by carrying on the work in the lines indicated very much more will be accomplished. I would therefore most earnestly recommend the use of volt and milli-ampere meters and the watch or clock with both the directing and alternating currents, in daily work. Data will thus be accumulated, which can not fail to be of value to the profession and the cause of electro-therapeutics will be advanced along scientific lines.

79 Madison Avenue.

SOCIETY PROCEEDINGS.

Association of American Physicians.

*Thirteenth Annual Meeting, held in Washington, D. C.,
May 3, 4 and 5, 1898.*

FIRST DAY.

Dr. F. C. SHATTUCK of Boston, delivered the president's address. He said it was 450 years since this country was discovered, and 250 years since what is properly called a hospital was founded. In the large cities, in the early days, there were very few poor persons, and the neighbors all helped each other. Later, when Irish and other nationalities began to come to this

country, and the older cities grew and new ones were created, there gradually appeared what might be called a poorer class, and these hospitals were opened for the care of the sick poor. At first, hospitals were started by private subscription, but as cities grew larger taxpayers were called on to support these institutions for the care of the sick poor. The medical profession has done much without pecuniary reward, but the physician gains experience and indirectly is assisted by attending these hospitals. The returns which physicians gain from this very work are ample. Virtue is not its only reward. Hospitals for the poor may be all very well, but there are also hospitals for the rich, although these two terms, poor and rich, are relative. Persons who could pay for an occasional visit were unable to stand prolonged medical attention, and the poorest necessarily need the best attention, because their surroundings as a rule are not favorable. Medical dispensaries and hospitals are free to all who need them and should be denied to those who do not need them. Questions should be asked; every claim should be scrutinized. The matter is in our hands. If the profession would refuse to help selfish institutions there would be fewer undeserving sick poor. Still, the hospital is an education for the physician. It advances his knowledge. The clinical teacher must study his cases carefully. The didactic lecture is gradually falling into decline. The teaching hospital is not free from blame. Complaints against such institutions have arisen of late in England, and also in this country, and there are some good grounds for these complaints. In his own experience in the Massachusetts General Hospital he has had to turn away cases who were not deserving. Some cases come to get information as to whether their physician was right, and people come from the country and think they have the right to free advice at the hospital, not knowing that the city hospitals are only for the taxpayers in the city. He referred to a case of his own knowledge where a physician had sent a patient to the dispensary, asking for free consultation. In the Massachusetts General Hospital dispensary many cases have to be excluded as unworthy. There a clerk is employed at a salary of \$500 a year to weed out undeserving cases. Another ground for complaint by physicians is the attaching of pay wards to hospitals which are supposed to be free. A hospital which can not be supported without this should close its doors. He referred to one hospital which had an income of \$55,000 a year from its private rooms. Many cases have to be treated in hotels and boarding-houses, who are able to pay for both attention and board. Such cases should not come to a charity hospital but should be cared for in a special hospital which is accessible to them. The small hospital makes good return on its investment. Those who are with hospitals are in a better position to treat cases than those without them. The using of pay rooms and pay wards attached to a charity hospital, to which only some physicians can attend, is in the nature of a medical trust and commercialism tends to degrade the medical profession. He mentioned one hospital that had a few private rooms and where patients pay a small amount for beds in the public ward. Such institutions can be established for clinical teaching.

Dr. S. J. MELTZER of New York, then read a paper entitled

CONGENITAL STENOSIS OF THE PYLORUS IN INFANTS.

After a brief review of the literature he said that he had had but four cases of this trouble. It seems to be becoming more common, or else the cases are more easily recognized. After the first case recorded was recognized there was a long interval, and then many cases seem to have been observed within a short period. In five cases the diagnosis was made and operation done and the lives of these were saved. Several physicians have made a diagnosis by having seen others at the postmortem. He then referred to a case in which he had made the diagnosis, and showed a very beautiful specimen in a child which had during life vomited occasionally and had great trouble with its nursing and feeding. Free hydrochloric acid was present in the matter vomited. It took its food greedily. By the use of diluted carbolic acid and bicarbonate of soda the food was held for some time, but gradually the child again began to vomit and then succumbed. He found a stenosis of the pylorus and atony and dilatation of the stomach. The child was forty-four days old when it was operated on by Dr. Willy Meyer. He did a gastro-enterostomy and used the Murphy button. The child lived a very short time after this. He then explained the gradual change which took place in the stomach in this trouble, and discussed briefly the diagnosis and treatment in these cases.

Dr. I. ADLER of New York, also showed some specimens of this same malformation and explained his method of treatment. He did not use the Murphy button. In his cases he found hypertrophy of the circular fibers, but the longitudinal fibers were very little altered.

Dr. A. JACOBI of New York, referred to a case which he had seen very recently and mentioned other cases, and said that this contraction of both ends of the stomach was probably the cause of this hypertrophy.

Dr. MELTZER, in conclusion, said that he had mentioned this hypertrophy of the muscles in relating his case.

Dr. D. D. STEWART of Philadelphia, then read a paper entitled

GASTRIC CARCINOMA ASSOCIATED WITH HYPERCHLORHYDRIA,

related a number of cases of this trouble and spoke especially of the position of the cancer. He said that a positive diagnosis was very difficult, especially when the cancer included an ulcer in which a certain amount of gastric fluid persists, even after the symptoms of this disease have been marked for a long time. He related at great length a case of unusual interest in which the operation was made before the patient came under Dr. Stewart's care, which showed that there was apparently a diffuse carcinoma, the stomach being too much involved for a gastro-enterostomy. One of the omental glands was found to be cancerous. In spite of all this the patient recovered from the operation and apparently became well. The symptoms returned later on and Dr. Keen was consulted. The case would have been considered one of chronic ulcer had not that gland been examined. The patient died after the second operation. The autopsy showed that there was a very large cancerous ulcer with a thickened cancerous pylorus. He had sent specimens to different pathologists for examination and had received a variety of opinions, some saying it was tuberculous and some asserting it was cancerous, which was right.

Dr. W. E. FISCHER of St. Louis, reported an unusual case of disease of the stomach in which there was voluntary vomiting, no pain, and the patient gained in weight. The examination of the stomach was negative. Later on a tumor was felt. He was put on a strict diet for some time; after that he could eat anything. A gastro-neurosis was suspected. He used carbolio acid and morphia. After this the patient took solid food three times a day, and later on he had pain; the tumor increased in size; he was not able to take any solid food and the pain grew excessive. An operation was advised, the abdomen opened and a large tumor found in the pylorus, but nothing could be done and the patient died.

Dr. Wm. H. WELCH of Baltimore, in discussing the diagnosis of Dr. Stewart's case, said that he had examined two nodules, one from the lymphatic glands and the other from the omentum, and the diagnosis seemed clear. It surprised him that it was diagnosed tuberculous by another physician in Philadelphia. He supposed that the follicles must have been mistaken for a tubercle. Notwithstanding this discrepancy the fatal end came. There was no difficulty in making the diagnosis and the clinical results must make physicians skeptic as to the value of microscopic examinations. He suggested sending specimens to Councilman, Prudden and others and was glad that they agreed with him. The apparent recovery is interesting. Multiple cancer is explained by being due more to implantation rather than to metastasis. It is due perhaps to contact. The specimen seen at the autopsy was in such a stage of decomposition that it was difficult to make out, but it was clearly an adenoma. There was a diffuse thickening of the anterior wall of the stomach.

Dr. J. C. HENMETER of Baltimore spoke of the one in which the gastric secretion was affected by the cancerous growth. He said that Dr. Mall of the Johns Hopkins University had been carefully studying certain cells of the stomach glands, and finds that unless these are affected the gastric juice is still secreted. These are so-called border cells, and we can sometimes have free hydrochloric acid and a carcinomatous ulcer in the same stomach. Heidenhain and Lange have done much work in this direction, and they say that ulcers in the pyloric region of the stomach do not always help in the secretion of hydrochloric acid.

Dr. JAMES TYSON of Philadelphia referred to a case which he had recently in a hospital, a man about 60 years old, who complained of great pain and tenderness in the stomach. The matter vomited was acrid and a tumor was apparent in the abdomen. He was put upon milk diet. When he first came in he lost forty pounds, but after he was given milk diet he improved rapidly and finally sufficiently recovered to go to work, but the tumor was still apparent and the test meals gave the same results. A certain number of cases of this kind seem to show the presence of free hydrochloric acid, and the matter vomited showed that we must be slow to draw conclusions.

Dr. W. W. JOHNSTON said that the improvement in these cases is so marked that there must be some explanation, and it may be in part that the gastric catarrh which accompanies

these troubles is improved by the treatment. A case of cancer of this kind gets better under treatment and often goes back to solid food and gains flesh, but in the end dies. This goes on to show that while our treatment is not curative it is beneficial.

Dr. D. D. STEWART of Philadelphia, in referring to Dr. Welch's diagnosis of his case, said he thought it was a case of cancer and treated it as such, and as for the gaining of weight in these cases, after treatment, one man went from 110 to 175 pounds.

Dr. F. P. KINNICUTT of New York said that even without a change of diet cases improved. In one instance he noticed a gain of twenty pounds and now the man is getting better.

Dr. E. G. JANEWAY of New York referred to two cases of gastric carcinoma in which there was a gain of forty pounds after washing out the stomach and giving proper treatment, but four months later the patient declined, had severe pains, returned to liquid diet and in three months died. The usual diagnostic rule of urea excretion failed in this case; the temperature for eight months was from 101 to 102 degrees. In one case there was also a change in urea secretion, and the patient, who was in bed, could always take food better sitting up than when lying down, the position probably removing the cancer from contact with the food.

Dr. CHARLES G. STOCKTON of Buffalo said that it was remarkable that in some cases of gastro-enterostomy successfully performed there was gain in weight and improvement. There may have been food stagnation with loss of weight, for if that ceases from whatever cause, the patients will gain weight.

Dr. A. H. SMITH of New York referred to a case of his in the Presbyterian Hospital in which there was the presence of hydrochloric acid but no lactic acid. The patient was very miserable so that he could not get out of bed, but on treatment he rapidly grew better and acted as assistant in the ward. He returned to his home and for five months had fairly good health, but later on grew worse and died. Evidently he had a cancer.

Dr. D. D. STEWART said, in conclusion, that his patient was exceptional in that he did not have to go to bed, and he gained sixty-five pounds.

Dr. SIMON FLEXNER of Baltimore then read a paper entitled

GASTRIC SYPHILIS, WITH A REPORT OF A CASE OF PERFORATING SYPHILITIC ULCER OF THE STOMACH.

He has collected the histories of cases of Chiari. In 243 cases of syphilis which came to autopsy, two were evidently cases of ulcer of the stomach due to this trouble. Some cases are hereditary and some are acquired. In the case he refers to, the history dates from 1892; the death occurred in 1896. The patient had ascites and edema of the lower extremities and the scrotum. The ascites was tapped, grew less, and the fluid was inconsiderable. Death came suddenly after a hearty meal. Just before death there was great abdominal pain and tympanites. The autopsy was a sero-fibrinous peritonitis. There was a perforation in the base of the stomach. There were several organisms in the peritoneal contents, among which were the bacillus aerogenes capsulatus and the colon bacillus. The liver contained a large gummatous mass. The diagnosis was based on microscopic examination.

Dr. I. ADLER of New York then read

SOME OBSERVATIONS OF CARDIAC SYPHILIS.

He spoke of the various forms of syphilis in the heart, such as gumma-endometritis, etc. The anatomic diagnosis is not infrequently doubtful. He examined the hearts of young infants. In four hearts of babies of a few months old he found signs of syphilis. It is hard to make this trouble out, for to the naked eye the heart is apparently normal. He hardened them in formalin and stained and examined them. In two there were no signs of syphilis. In the other two characteristic lesions were found. In one infant who was two years old there was one small patch found in the internal coat and a slight infiltration. The other child died at the age of 3½ years, from what was apparently catarrh, and there were no signs of disease in the heart, to the naked eye. He thinks that the blood vessels are often the primary seat of the disease and the muscles are attacked later. In many cases the disease might be arrested early, if a diagnosis were made, but as a rule the disease is advanced too far when the clinical symptoms appear. There are really few distinctly diagnostic symptoms to the naked eye to distinguish it from other troubles. Often traces of syphilis can be found in other organisms than the heart. He thinks it is necessary to make methodic examinations of each case and to suspect syphilis in every case of heart disease, and give the iodid and mercury, as well as digitalis and other such drugs, and if it is not syphilis no harm will be done.

Dr. E. G. JANEWAY of New York then read a paper entitled

DANGER OF ERROR IN DIAGNOSIS BETWEEN CHRONIC SYPHILITIC FEVER AND TUBERCULOSIS.

He briefly reported a number of cases of a similar character. One case was a young man who had been sent to a sanitarium for consumption. He continued to grow worse, and an examination revealed syphilis. No tuberculous symptoms could be found and hepatitis had been the cause of his ill health. He promptly recovered under treatment. In one case there was fever, sweating, and pain in the side. He had been advised to go to the country on account of supposed tuberculosis of the right lung, but a later examination showed two ribs to be diseased and a small sinus apparent. Antisyphilitic treatment removed this trouble. He instanced several cases of this kind; one case in which a prominent physician had made a diagnosis of tuberculosis when no such lesion existed. In one case of a young child he suspected syphilis, but was persuaded into believing it a case of tuberculosis, and sent it to the hospital for treatment. The child died and the autopsy revealed the true condition. The specialist may be able to recognize these cases, but it must be remembered that the majority of them fall into the hands of the general practitioner. In obscure cases of apparently tuberculous miliary sepsis, syphilis should always be borne in mind as to the possible cause.

Dr. I. E. ATKINSON of Baltimore said that nothing shows more clearly the want of accurate attention on the part of the medical profession than this very frequent presence of syphilis complicating all sorts of obscure conditions. This is especially true in the class of cases referred to. The disease may simulate continued fever, although fever may be remittent in character, which may make us suspicious. He referred to a sailor in a hospital, from Calcutta, who had an enlarged liver and a severe cough, but no tubercle bacilli could be found. Albumin and casts were both present. He denied having syphilis and hepatic abscess was suspected and he was aspirated several times without result. The plasmodium of malaria was looked for but not found. His right testicle began to enlarge. He was given iodid of potash and in three or four days he had no fever and recovered entirely. It is in the late cases where the fever is apt to be obscure.

Dr. MELTZER of New York, said that Hansemann reported a number of apparent cases of tuberculosis in which no tubercle bacilli were present, and which recovered under the use of iodid.

Dr. F. P. KINNICUTT of New York, said that many had seen the presence of syphilis at the autopsy when they had not suspected it during life, and he also described some cases.

Dr. CHAS. G. STOCKTON of Buffalo, said that an examination of the blood may assist in the diagnosis, and that tuberculin test might be used to advantage in these cases.

Dr. V. C. VAUGHAN of Ann Arbor, said that the two affections might exist in the same person, and in many cases would give considerable trouble. The temperature curve is greatly different from that in tuberculosis. The finding of the bacillus of tuberculosis would confuse us.

Dr. JAMES TYSON of Philadelphia, thought that the use of antisyphilitic treatment would make the diagnosis.

Dr. JANEWAY said he had examined the blood for the plasmodium and leucocytes; the tuberculin test was not used; the antisyphilitic treatment furnished the test and produced a cure. In some cases it is extremely dangerous to use the tuberculin test. He mentioned a case in which such bad results had been brought about that the patient could hardly be induced to keep from suing the physician for malpractice. He has seen the two diseases in the same person. He used iodid of potash and bichlorid of mercury in combination with cinchona.

Dr. E. G. CUTLER of Boston, referred to a case in which tuberculin gave the characteristic action when no tuberculosis was present.

Dr. WM. S. THAYER of Baltimore, then read a paper on
NEPHRITIS OF MALARIAL ORIGIN.

He dealt largely in statistics based on cases in the Johns Hopkins Hospital. He referred to the frequency of albuminuria in malarial fever with other diseases. In looking over the statistics, and in his own cases, he found that a large proportion of cases of malarial fever had albuminuria and casts but principally the cases of estivo-autumnal fever. In 758 cases of malarial fever there was albuminuria in 321 and casts in 121. Albumin was present in nearly one-half the cases. He had nineteen cases of acute nephritis of malarial origin. He found that in general his own statistics agreed largely with others he had collected, except in some few cases. In scarlet fever there was a certain number of cases of albuminuria and casts, also in diphtheria and typhoid fever. Albumin is probably present in about one-half the cases of scarlet fever, and malaria seems to be the cause of more cases than is generally supposed, but

not as often as in yellow fever, and for this reason we can not place too great reliance in the presence of albumin in yellow fever. Out of 152 cases of malaria there were fifty-two cases of nephritis. Seven were tertian, ten estivo-autumnal and three of varied type. There were thirteen recoveries and four deaths. Nine were doubtful. He also gave statistics of the age, sex and color of the cases. He thinks there is a possible etiologic relation between nephritis and malarial infection.

Dr. F. FORCHEIMER of Cincinnati, wished to corroborate the statement as to nephritis in estivo-autumnal fever. There are many such cases in Cincinnati. The kidney rarely escapes, and he found the majority of cases in children. He had found in a certain number of cases of nephritis the presence of a pigment which probably came from the blood. The urine was light above and dark below. There was blood pigment and casts. In most of them the pigment was a reddish-brown. This cause was described to be due to plasmodium, but he has studied a number of these cases and has found the pigment in connection with malarial fever. He showed a specimen from a child sixteen months old. He has made no complete chemist analysis but thinks it may be melanin.

Dr. WM. OSLER of Baltimore, in referring to these interesting cases of Dr. Thayer, said that the importance of albumin in the diagnosis of yellow fever from malaria lay in the fact that in yellow fever the albumin was found early, in the first twenty-four or forty-eight hours. In the hospital they had had no single case of malarial hematuria which could be attributed to the use of quinin, and many physicians in the South hesitate to use quinin on account of this complication.

Dr. JACOBI asked if the findings of Dr. Thayer were the same for every year. A number of observers say that they find no albumin for a number of years, and then in a large number it is found. He had seen a number of cases but none had had albuminuria.

Dr. I. E. ATKINSON has for years felt convinced that malaria was an important factor in nephritis, and it had been pretty constantly found in every outbreak of malarial fever, more so than we usually think. One of the difficulties in the way of decision is to know whether the nephritis is due to the malaria or the malaria to nephritis. Another point to note is whether in localities where mortality statistics are kept it is found that kidney complications are more common than where malarial fever does not exist. In Maryland there have been no vital statistics until the present time, but in Baltimore the records are carefully kept.

Dr. TYSON said that he noticed in Philadelphia what Dr. Jacobi noticed in New York, that some cases were of a mild type, and that there were severe cases at other times.

Dr. M. H. FUSSELL of Philadelphia, said that in Frankford, Philadelphia, he had seen a number of cases of malaria, but in none had he found nephritis and in none albuminuria.

Dr. THAYER, in answer to Dr. Forcheimer, said that he had seen very few cases in children; that only recently had there been a children's ward in the Hopkins Hospital, but he had an interesting case referred to him by Dr. Northrup. He has not had a case in which quinin has had an influence. Dr. Ram-poldi of Rome, writes that he has never seen a case of quinin hemoglobinuria recorded from the Roman Campagna. He noticed that there were different epidemics in different years. In the 216 cases sixteen occurred in 1896, and last year there were very few cases.

Dr. W. T. COUNCILMAN of Boston, then read a paper entitled

ACUTE INTERSTITIAL NEPHRITIS,

an acute non-suppurative inflammation of the kidney, characterized by cellular and fluid exudation in the interstitial tissue, accompanied by but not dependent upon, degeneration of the epithelium. The interstitial lesion consists in the presence of cells similar to those described by Unna as plasma cells. These cells are due to emigration from blood vessels and proliferation of the emigrated cells. They are formed in other organs, chiefly in the spleen and bone marrow from lymphoid cells, and are carried to the kidneys by the blood. Accumulations of plasma and lymphoid cells may be found in the blood vessels of the kidney without any interstitial lesions. Such cases of acute interstitial nephritis are frequently found in the infectious diseases of children, notably in diphtheria and scarlet fever, but they may be found under other conditions.

Dr. WM. H. WELCH of Baltimore said that this work of Dr. Councilman was of great value. He has had opportunity to study these specimens and he agrees with him as to the origin. They have emigrated from the blood cells and from the lymph vessels. It is interesting as evidence that the lymphoid cells can emigrate as well as the polynuclear cells. He spoke of this last year in connection with Dr. Gilchrist's paper, and reported

two effects of chemotactic stimuli quite distinct from each other. We have three sorts of cell accumulations: plasma cells, polynuclear formations and lymphoid cells. It is a great advance in technique that we are able to differentiate these different cells.

Dr. TYSON said this was an exceedingly interesting study and showed the results of careful investigation.

Dr. COUNCILMAN said in conclusion, that some of the cases recorded were due to bacteria. These plasma cells have something to do with inflammation, and may possibly have some connection with the healing of wounds.

Dr. R. H. FITZ of Boston, then read a paper on

A CASE OF MYXEDEMA AND ALBUMOSURIA; TREATMENT WITH THYROID EXTRACTS; DEATH.

He said: The case is reported for the purpose of calling especial attention to the occurrence in myxedema of a rare condition (albumosuria). It is, therefore, desirable in examining the urine in myxedema to bear the above fact in mind, since albuminuria is relatively frequent and albumose might easily be mistaken for albumin unless the customary test with heat and nitric acid be duly controlled. The communication has an additional interest in showing that, despite temporary improvement under the use of thyroid extract, this remedy is not infallible in myxedema. He gave the history of the cases and spoke of the difference between albumose and albumin, and then tested a specimen in the presence of the association. The addition of nitric acid caused the precipitation of albumose, which heat dissipated, and the application of cold caused it to return. He showed several illustrations.

Dr. V. C. VAUGHAN said that these are rare cases. The presence of a small amount of albumose is very common; some say that it is always normally present in small amounts. So far as he knows this is probably true, but the large amounts as noted are quite rare.

Dr. FITZ said, in conclusion, that his paper contained references to these illustrations of small amounts and he had mentioned the work of Bence Jones. There have been seven cases recorded in Germany and Holland. He thinks that often these cases are mistaken for albuminuria, and they are really more common than is supposed.

SECOND DAY.

Surgeon-General GEORGE M. STERNBERG, U. S. A., read a paper entitled

BACILLUS ICTEROIDES (SANARELLI) AND BACILLI X (STERNBERG),

in which he referred to his first work: then the second paper on the subject, and in it he replies to Sanarelli's article in the *Annales de l'Institut Pasteur and Centralblatt für Bakteriologie*. The paper copies in part his work and has done him great injustice. He regrets that it is necessary to correct wrong statements made by Dr. Sanarelli. He quoted what Sanarelli says he said and then stated what he really did say. He thinks there is not one micro-organism which can be indisputably said to be the specific organism but he also thinks that one of them may be. His work is not taken up anew but is a continuance of what he began some time ago. His bacillus x was found in the contents of the intestines in some cases, but Sanarelli did not find any there at all. It is very bad teaching to say that the organism can not be found in the contents of the intestines, for if it were not there, there would be no necessity for disinfecting the clothing, etc. The alvine discharges of the sick are very dangerous. Sternberg did not make any clinical notes because he had not the time, but he had great experience while Sanarelli had no experience in the disease. Sternberg had had the yellow fever in 1875, and he had seen a great many cases and always made an autopsy and collected material for bacteriologic examination, and while in Havana he personally made forty three autopsies in four months, and he always made his autopsies from two to five hours after death. This was against the law in Havana, but the authorities connived at it and assisted him greatly. He obtained the cultures from Dr. Roux, in Paris, of Sanarelli's icteroid bacillus, and there was a difference between them. The organism of Sternberg bacillus was motile in Havana, but here it was not, although the flagella could be seen stained. He passed the culture through guinea-pigs and found that the bacilli became motile again. If neither organism is the specific organism of yellow fever, then one is just as good as the other. Sanarelli experimented on man, but Sternberg has not done that yet.

Dr. A. C. ABBOTT of Philadelphia, asked if Dr. Sternberg had had a parallel experience with the colon bacillus and others of that kind for comparison's sake. He feels, personally, that the two organisms are identical. He questions its viru-

lence. The colon bacillus is sometimes virulent and sometimes not.

Dr. V. C. VAUGHAN of Ann Arbor, said that Dr. Novy had begun work on Sanarelli's germ a year ago and there is no proof that Sanarelli's germ is the cause of yellow fever. His experiments on man are simply ridiculous. He did not know what was the matter with the man he used in the hospital, and when he says the case showed marked effects, we do not know what he means. We might get marked effects from other germs. He does not believe that yellow fever is caused by the organism, and thinks, as they do in the South, that yellow fever never originates in the North. Sanarelli's germ was not affected by freezing and thawing, and his observations on agglutination were made in a test-tube, and it is absurd to study agglutination in that way. The blood of his students in the university had caused agglutination and they were healthy men. Sanarelli's germ is very virulent and caused agglutination.

Dr. WM. OSLER of Baltimore, said that much stress had been laid on the work by Dr. Archinard in the recent epidemic that seemed most favorable to the Sanarelli bacillus. The experiments of Sanarelli on man are not ridiculous; that is not the proper word. Almost every dose of medicine is an experiment. We do not know, for instance, what effect iodid of potash will have in certain conditions. It is only an experiment. The experiments in medicine should be recognized.

Dr. STERNBERG said that we want comparative experiments with the colon bacillus. This disease may be a fecal disease. The typhoid bacillus may be an off-shoot of the colon bacillus. Yellow fever has a toxin and the tetanus bacillus is also hard to find. We are not ready to accept Archinard's work because it is so much better than Sanarelli claimed.

Dr. THEOBALD SMITH of Boston, then gave a résumé of "Comparative Studies of Bovine Tubercle Bacilli and of Human (sputum)." This was a résumé upon fever cultures of tubercle bacilli from human sputum and of five cultures from cattle. One culture each from the pig, and the horse and the cat were also included in the series. Differential characters relating to the morphology of these different bacilli, their biology and pathogenic power as tested upon guinea-pigs, rabbits, pigeons, mice, cattle, was discussed. The bovine bacilli are sharply distinguishable from the human bacilli by their greatly augmented pathogenic power. The paper closed with a discussion of the probable value of the differential characters in definitely tracing the sources of human disease occasionally referred to the lower animals, especially cattle, and of the necessity of a closer comparative study of tubercle bacilli from different forms of human tuberculosis.

Dr. ABBOTT said that Dr. Smith had given much attention to this subject, and there has appeared a similar piece of work by Rabinowitsch. He claimed that some butter contained the tubercle bacilli.

Dr. SMITH, in reply, said he had never found tubercle bacilli in butter, and that was outside of the work he had outlined.

Dr. OSLER said it was interesting to determine whether the bacillus causing the lesions of scrofula had the same differences as the other organisms and as the difference in animals, and the difference in inoculation in guinea-pigs, rabbits, etc. Fever is an important prognostic sign.

Dr. SMITH said that this was in his paper but he had passed it by as the paper was so long. He referred to the recent work of Euclaire. He had endeavored to help this work by selecting four cases of tuberculosis of different kinds and he inoculated guinea pigs in the abdomen and the inoculation proved fatal to all.

Dr. SIMON FLENNER of Baltimore, then read a paper entitled "Pseudo-Tuberculosis Hominis Streptotricha." He first spoke of streptotriches in general, and then described a case, that of a colored male, aged 70 years, who presented the symptoms and physical signs of pulmonary and peritoneal tuberculosis. No sputum was obtained. The autopsy exhibited extensive consolidated foci in the lungs, which resembled, in gross appearances, areas of caseous pneumonia and nodules in the peritoneal cavity which were indistinguishable from true tubercles. The bacteriologic examination revealed no tubercle bacilli, but a micro-organism in the lungs and "tubercles" which belong to another genus, and for which the name of streptothrix pseudo-tuberculosis is proposed. This is an exceptional case but these organisms ought to be thought of and always looked for in doubtful cases.

Dr. S. J. MELTZER and T. S. CHEESMAN of New York, then read a paper entitled "An Experimental Study of the direct Inoculation of the Spleen with Micro-organisms, and a Contribution to our Knowledge of the Importance of the Lesion of a Body-tissue for the Settlement and Development of Bacteria within it." It was the result of a long series of experiments

in which organisms were inoculated and injected into the spleen, and after a few hours autopsies were made which showed that the organisms had disappeared from the spleen and were found in other organs of the body, while the culture in the spleen is usually sterile. Are these bacteria destroyed in the spleen or are they carried out? The tying of the portal vein did not prevent the spleen from being sterile. When certain parts of the spleen were ligated they were found to contain bacteria, and when the bactericidal power of the blood is exhausted the bacteria multiply very rapidly.

Dr. WELCH said that this demonstration was very welcome but hardly seemed conclusive evidence that bactericidal substances are less in the spleen than elsewhere. The ligation of the spleen caused the appearance of the bacilli. It is likely that the bacteria in the ligated areas is analogous to the bacteria found in cauterized areas. They were there because the spleen was damaged.

Dr. A. JACOBI of New York, in referring to these statements, said that when these tissues are normal we do not find bacterial invasion. Diphtheria organisms will not grow in a healthy throat with the exception of the healthy tonsil. Tuberculosis will settle in the ends of the bones because there circulation is slower. The spleen changes in the course of the day. After meals it is larger and there are many organisms in it. A person has chronic malaria and is given a large dose of quinin, and then there comes on a severe chill because the quinin contracts the spleen and it is squeezed like a sponge, and the chill is the response. He has noticed the same thing in giving ergot in malaria.

Dr. MELTZER, in referring to Dr. Welch's statements, said he agreed with him. He also replied to what Dr. Jacobi had said.

Dr. M. H. FUSSELL then read a paper on "Acute Leucemia," in which he described two cases of his own. Fifty-six cases had been collected in all, and statistics showed that it was most common between the 10th and 30th year. Five cases were over 40 years old; thirty-three were males and twelve were females. He gave a most careful clinical history of these two cases and showed the specimens under the microscope.

Dr. OSLER, in discussing these cases, said that the limit of sixty-three days for an acute case was rather narrow. There are cases which are called acute which run from three to four months. He has a patient now with enlarged glands, and has fever, and this is practically an acute case. Glandular enlargement often disappears under treatment with mercury.

Dr. E. G. JANEWAY of New York, said that out of seven cases that he had seen, one had acute glandular enlargement; one had subacute leucemia with enlarged tonsils.

Dr. F. C. SHATTUCK of Boston, asked if there were any autopsies held in the cases that Dr. Fussell had quoted and in his own cases. Dr. Shattuck also related a case of his own which was sent to him by another physician who said it was leucemia, but when he saw the case he thought it was one of kidney trouble. Dr. Fussell said that autopsies had not been made in all the cases. He said he had excluded many cases collected by Ebbstein which were doubtful, especially those cases in which no autopsies were performed.

(To be continued.)

Ohio State Medical Society.

Fifty-third annual meeting, held in Columbus May 4-8, 1898.

The Address of Welcome, delivered by Dr. E. J. WILSON of Columbus, was responded to by the President of the Society, Dr. WILLIAM H. HUMISTON of Cleveland.

The first paper read was on

PARTIAL CATARACT.

by Dr. C. F. CLARK of Columbus. He said: Even among young people some opacity of the lens is often present although undetected, and as age advances certain changes invariably take place in its character, and in a large proportion of those who are never led to suspect it, a careful inspection will reveal the presence of incipient cataract. It is often only in its advanced stages that those who have cataract present themselves for treatment. The average age of the members of this Society is such that it is probable that an investigation would reveal the fact that a large number of those who make complaint of nothing more than a slight dimness of vision would find upon careful scrutiny that either the radiating striae or the outer layers of the periphery of the crystalline lens were undergoing changes which would justify the diagnosis of partial or incipient cataract. It does not follow that all of those in whom such changes are found should look forward to the development of mature cataract or that of necessity anything should

be done for them, but it is a fact that in a certain proportion of these cases asthenopic symptoms do present themselves which require attention. These symptoms are more frequently observed when changes in the lens make their appearance before the period in which the accommodative power has been gradually reduced by the advance of presbyopia. If the rigidity of the lens which often accompanies opacity makes its appearance before the natural development of presbyopia has caused a cessation of the activity of the ciliary muscle, the action of that muscle in its efforts to relax the suspensory ligament and thus bring about accommodation being unavailing, leads to congestion and in many instances to pain and discomfort. In a large proportion of cases the development of opacity of the crystalline lens is due to degenerative changes in the choroid coat or the whole uveal tract. When true cataract develops there is usually, even in the early stages, a marked difference in the degree of transparency of the various portions of the lens. The nucleus which in the normal eye is more dense than the cortical layers, may become proportionately still more dense, thus accentuating the distinction between nucleus and cortex. The opacities of the outer layers of the lens may assume a great variety of forms in accordance with the portion of the cortex affected, and these varying conditions will be accompanied by corresponding variations in the symptoms. Surprising as it may seem, dimness of vision not infrequently coexists with well-defined incipient cataract. Dimness of vision, therefore, while usually present, may be absent, and it may result from so many other causes that its value as a symptom is comparatively slight in the early stages of the development of lenticular opacity. As long as the central portion of the lens remains clear the vision may be excellent. The diminution of vision usually approaches so insidiously that, unconsciously, the patient often adjusts his standard of acuity of vision to that of which his own eyes are capable. When a patient is so situated that he can afford to await the maturity of a cataract it undoubtedly adds to our assurance of success and every chance in the patient's favor should be taken advantage of when dealing with so serious a matter as the restoration of vision, but in a number of cases on which the essayist had operated during the last few years, in which the circumstances made it necessary to remove immature cataracts, the results have been so admirable as to convince him that we have often unnecessarily delayed operation on account of incomplete opacity of the lens. Since we have learned to adhere strictly to the principles of asepsis, the danger of an operation upon an immature or partial cataract has been materially reduced, and if the patient is so situated that years of waiting mean years of privation, and that pitiful relaxation of his hold upon the world and the reduced physical condition from the mental depression that so frequently accompanies blindness, we should undoubtedly operate even if the cataract is not mature.

Dr. F. O. MARSH of Cincinnati then read a paper on "Some Medical Aspects of Capital Punishment." After reviewing the usual modes of inflicting capital punishment he referred to the use of drugs for this purpose. The only poisonous drug of any prominence or importance which is known to be absolutely free from pain in its action, morphin, is slow in action, might be rejected by the stomach and might prove a failure even when given in a supposed fatal dose. Probably the best agent would be chloroform. The use of chloroform is extremely simple, devoid of all complicated and cumbersome paraphernalia and is the most inexpensive. Death by this means is essentially painless and perhaps would supervene in a half hour.

Other papers were: "Functional Heart Murmurs," by C. F. HOOVER of Cleveland; "Psychic Treatment of Diseases," by PHILIP ZENNER of Cincinnati.

In "Intestinal Obstruction, Operation and Recovery, with Report of Case," by SHERMAN LEACH of Mt. Sterling, the essayist believed that in such cases operation should be resorted to before fatal peritonitis develops. After due trial with the various remedies, calomel, oil, salines, aided by rectal enemata of various kinds, if the bowels are not opened and any symptoms of obstruction exist, prevent peritonitis by operating at once, without waiting for symptoms of peritonitis. The case reported was one in illustration.

NOTES ON SYPHILITIC LARYNGITIS, WITH CASES

was read by HOWARD STRAIGHT of Cleveland. He said: The four conditions of the larynx most often requiring differentiation in a given case are lupus, carcinoma, syphilis and tuberculosis. Lupus of the larynx ordinarily attacks this organ secondary to cutaneous lupus. As a rule it attacks the epiglottis first. It is characterized by a slow but progressive destruction of tissue. If there is any question as to its being syphilis in a given case it can easily be settled by administering

increasing doses of iodid of potash. If the diagnosis lies between carcinoma and lupus, the microscope might have to decide the question. Carcinoma of the larynx is a rare disease. While carcinoma may attack any part of the larynx, it usually attacks the naticular bands first. The diagnosis by the aid of the microscope is as a rule easy. In certain cases the diagnosis ought not to be positively made until the patient has been subjected to increasing doses of iodid of potash. Tuberculosis of the larynx is a common disease. Anemia of the larynx, the pear-shaped condition of the arytenoids, the swelling of the interarytenoid space, the associated pulmonary tuberculosis, ordinarily make the diagnosis of the laryngeal condition easy. If any question exists in the mind of the laryngologist, the administration of increasing doses of iodid of potash will easily exclude specific disease. Syphilis of the larynx is a common disease. If mistaken for any one of the other diseases mentioned, and increasing doses of iodid of potash are not administered, the results may be deplorable. Such medication can in no event do great harm. If lupus or carcinoma, its administration for a short time is a matter of little consequence. In laryngeal tuberculosis anything tending to disturb the gastro-intestinal tract would be undesirable, and yet if any doubt as to the condition of the larynx exists the administration of the remedy is extremely valuable. Laryngeal tuberculosis and syphilis of the larynx may exist together. In such a case the increasing doses of iodid of potash ought certainly to be given. Theoretically the diagnosis of the conditions mentioned is easy; however, certain cases occur in which a positive diagnosis can not be made.

A paper on "Movable Kidney" was read by YEATMAN WARDLOW of Columbus.

"Monstrosities vs. Maternal Impressions," by GEORGE S. COURTRIGHT of Lithopolis, was a report of three monstrosities in three consecutive pregnancies. The first child was born after the mother had nursed the father while recovering from an accident. The other pregnancies followed in rapid succession. The Doctor gave it as his opinion that if the mother did not become pregnant again for four or five years, she might have a healthy, well-formed child. Almost five years after the birth of the last deformed child, the woman was delivered of a healthy, well-formed child, now a fine intelligent boy.

A paper on "Irrigation with Salt Solution and Other Fluids in Surgical Practice," was read by HUNTER ROBB of Cleveland.

On Wednesday evening there was a reception to members and visiting ladies, at the Great Southern Hotel.

SECOND DAY.

The Society was called to order at 9 A.M. The first paper was "A Summary of Certain Studies in the Morbid Anatomy of Epilepsy," by A. P. OELMACHER of Gallipolis, and was a report of the results obtained from eighteen autopsies. The most prominent anomaly in these cases was the large thymus body, and it was this peculiarity which led to the study of the literature, in which at least two other morbid conditions were found with the same anatomic features as were presented by these cases, namely, laryngismus stridulus and sudden deaths in adults with no assignable reason. Taken in their entirety, the morbid conditions found in these cases, and which have always been found in thymic asthma and thymic sudden death, make a picture of what the German pathologists style the "lymphatic constitution." Aside from the hyperplastic thymus there is a general lymphatic hyperplasia and a narrowing of the arteries, and often evidence of rickets.

The next paper was on

URIC ACID

by Dr. D. N. KINSMAN of Columbus. He said that uric acid may be retained in the body either as uric acid or urates. It is not a poison, and when retained in the body its effects are mechanical. It may exist free in the blood serum or be precipitated about the joints as urate of soda, or in other organs, or after a more or less prolonged retention it may be discharged in lithia acid storms through the kidneys. Its retention in the body is marked by a diminution of the urine and increase of vascular tension. Its discharge is accompanied by increase of urine and decline of vascular tension. The amount of uric acid which may be present in the body depends upon the aliments which are ingested, and the integrity of digestion and excretion, exercise, etc. Heredity plays an important part in the production of the uric acid diathesis. All persons having a hereditary or an acquired uric acid diathesis are in a state of unstable equilibrium, and circumstances determine whether the outcome shall be lithemia, gout, migraine, fibrosis, or some other dystrophy. The relations of migraine, epilepsy and asthma have long been recognized. The clue which joined them has not been very clear. That indigestion and putrefy-

ing contents of the intestines have an incidental relation to epilepsy and migraine has long been recognized, and it has been the custom of the profession to advise light suppers of milk and bread, because it has been learned that such a regimen was influential in warding off nocturnal seizures. The essayist has inherited migraine, which has been hereditary in five generations, and with it other gouty manifestations in the enlarged metatarso-phalangeal articulation of the great toes, urinary calculi, and frequent uratic deposits in the urine. On a few occasions, swelling and extreme pain in the great toe joints have been suffered, as well as lithic acid storms. Respiratory distress in fast walking is a precursor of the headaches, which subside after the attacks. As the attack declines the quantity of urine increases and often lets fall deposits of uric acid. After these storms, no amount of exposure, nor indiscretion in diet, loss of sleep or fatigue, which are very potent in causing the headaches at other times, cause it for some time thereafter, until uric acid has again accumulated. In addition to these symptoms, lithemia causes vertigo, slow pulse which often intermits, and vascular tension. The patient is irritable, moody, hypochondriac and hysteric. They have a great variety of digestive disturbances, disordered vision and flying pains in the limbs and about the joints. Imperfect digestion and dilation of the stomach are associated with large uratic deposits in the urine. Uric acid causes cutaneous eruptions, tonsillitis, pharyngitis, bronchitis, asthma or aggravates them. It retards the healing of wounds, builds stone in the bladder and infarctions in the kidneys. It causes a world of distress and then has gout to fall back upon. When the diagnosis is established, the treatment is obvious. Aside from the use of colchicum, there is nothing better than alkaline waters. Beyond this the food is the most important consideration. Meats, soups, glands which contain large amounts of uric acid, should be used sparingly or not at all. Carbohydrates and vegetable albuminoid substances, with no alcohols, should constitute the diet. Exercises frequent and prolonged, as well as methodic, should be prescribed.

Other papers were: "Lumbar Punctures," by J. R. WENNER of Cleveland, which reviewed the literature on the subject and reported forty cases that occurred under the care of the essayist: "Removal of the Cecum for Malignant Disease," by J. C. OLIVER of Cincinnati.

HENROTIN'S METHOD IN PELVIC ABSCESS

was presented by J. C. REEVE, Jr., of Dayton. The plan is as follows: Steady the cervix by vulsellum forceps and incise the vaginal mucous membrane at the cervico-vaginal junction either just behind or just in front of the cervix, avoiding the sides of the cervix. The anterior or posterior fornix is selected according to its respective nearness to the collection to be reached. After cutting through the membrane, continue the dissection bluntly by means of the finger or of the closed blunt scissors, adhering to the middle line of the uterus as in hysterectomy. By keeping thus against the firm tissue of the uterus, one can not go astray and is on safe ground. After getting quite above the cervix it is then safe to go straight to the objective point, provided the dissection is done by the finger aided by counter pressure by the other hand through the abdominal walls. After the fluid is reached the channel may be dilated, or if this does not enlarge it sufficiently a vertical incision in the middle line can be added to it, reaching short of the rectum or bladder. The cavity can then be packed or drained. It is the custom of the essayist, especially when there is much odor, to place a two-way tube, made by stitching two large rubber tubes together. The smaller, carrying in the solution, reaches to the top of the cavity; the larger drains its lowest parts. Both reach outside the vagina and so permit a frequent irrigation (with mild antiseptics), with no disturbance to the patient or attendant and sometimes requiring not even a bedpan. Several cases were reported.

In the "Incision less than one and a half inches in Appendicitis," by N. STONE SCOTT of Cleveland, he said that the only possible objection to the incision less than one and one-half inches is the delicacy of touch required and the substitution largely of touch for sight. Given the necessary tactile education, however, the advantages are the absence of liability to hernia, reduction of the period of convalescence and the cosmetic effect. Several illustrative cases were detailed.

THE OBSCURE CASES OF GALL BLADDER DISEASE

was by EDWARD S. STEVENS of Lebanon.

In a large number of the obscure cases of gall-bladder disease there will always be more or less doubt as to whether the gall-bladder and ducts are diseased at all. With a reasonable degree of certainty as to the location of the disease, there will always be more or less doubt as to the character of the disease, for there are other forms of disease which produce gall-bladder

disturbance besides gallstones and the inflammatory affections. In such cases the symptoms not yielding to treatment and being essentially chronic, it is eminently proper to advise an exploratory operation for the purpose of making certain the diagnosis. This may be advised in the first place because in the hands of one who is skilled in this work the danger is almost *nil*. In the second place the propriety of such advice may not be questioned because the exploration is the first step to be taken in a radical gall-bladder operation, and most of the chronic gall-bladder diseases require local treatment rather than medicinal if a permanent cure is to be effected. Even though an incurable malignant disease be discovered upon opening the abdomen, it is a great satisfaction to know what condition is present. It has happened in many cases that relief followed the simple exploration, although the abdomen was closed with the knowledge that malignant disease of or near the gall-bladder was responsible for the symptoms for which relief was sought.

The special order of business at the evening session was the Address in Medicine by H. A. HARE of Philadelphia. The address was upon the treatment of typhoid fever, the use of opium in diabetes, the treatment of aneurysm, the treatment of pulmonary tuberculosis, burns, improvements in the methods of producing anesthesia and the importance of recognizing the vasomotor system as a factor in disease and in the production of disease.

THIRD DAY.

BILATERAL PARALYSIS OF THE POSTERIOR CRICO-ARYTENOID MUSCLES OF THE LARYNX, WITH REPORT OF A CASE,

was presented by ALBERT RUFUS BAKER of Cleveland. The case reported was one in which a tracheotomy was made to relieve dyspnea due to paralysis of the posterior aryteno-cricoid muscle. The patient now wears a tracheotomy tube constantly, with a cork in it tied to a string. Whenever a suffocative attack comes on, he pulls out the cork and normal respiration is immediately restored, he then replaces the cork and soon goes on about his work as usual. A few weeks ago the patient secured a life insurance policy for \$2,000 in an industrial life insurance company. During the first year after the operation the patient had some difficulty in securing a satisfactory tracheotomy tube; they would break and get out of repair, and it became necessary to have a new one at short intervals, and they were also hard to keep clean, and from their irritating properties would frequently cause excessive granulations to spring up around the tube. To overcome all this, the metal tube was replaced by a soft rubber one, which was much more satisfactory.

Dr. P. J. KLINE of Portsmouth, reported "A Case of Cirrhosis of the Liver." The patient did not present marked jaundice, and in many respects the case was anomalous. Thus there was no distinct caput Medusæ, although the vessels over the abdomen were enlarged. The essayist felt that he was justified in excluding syphilis and alcohol as etiologic factors in the case. Unfortunately no postmortem was secured.

Dr. HENRY W. BETTMANN of Cincinnati, read an interesting paper on "The Clinical Importance of the Position of the Stomach." In few cases do we find the stomach and other abdominal viscera in the position usually assigned to them by the text-books. But many cases of displaced stomach, as well as of other viscera in the abdominal cavity, show no symptoms of disease or inconvenience therefrom. In many cases in which unpleasant symptoms were traceable to such malposition, the essayist had found the patients were greatly relieved by wearing an abdominal supporter.

"Intracranial Complications of Aural Disease; Prognosis and Treatment," was presented by ANDREW TIMBERMAN of Columbus.

The essayist referred to the frequency of intracranial complications of aural disease, and presented specimens illustrating the operation he would do for chronic aural trouble. It is difficult to say when a case is past redemption by operation. The essayist had seen patients brought in a state of coma, with a very rapid pulse, temperature 105 degrees with stertorous breathing, the coma so deep that an anesthetic was not required for operation, and yet the patient recovered. A last chance is nearly always given by the people who are interested, and these patients should have the benefit of a late operation.

The last paper before the Section was a voluntary paper on "The Dyspeptic Stomach and How can we Secure a Speedy Cure," by Dr. ALBORS of Fulda.

Schulze's Swinging for Infants' Bronchiolitis. Schilling has been successful in saving a few cases of bronchiolitis in very young infants with apparently grave prognosis, by swinging them according to the Schulze method.—*Munch. med. Woch.*, No. 11.

Medical and Chirurgical Faculty of the State of Maryland.

One Hundredth Annual Session, held at the Hall of the Faculty at Baltimore, April 26 to 29, 1898.

(Concluded from page 1175.)

Dr. HENRY M. THOMAS then read a paper on

FACIAL PARALYSIS; A STUDY OF EIGHTY ODD CASES.

He said there was peripheral facial paralysis or Bell's paralysis, and all of his cases were from the medical wards of the dispensary of the Johns Hopkins Hospital. He had 85 cases of which 49 were women and 36 men, the usual proportion. One woman had two attacks on the right side. Of his cases 43 were paralyzed on the right side, 33 on the left side and 2 on both sides. Of the ages, in 1 it was congenital, 5 were between 1 and 10 years, 17 between 11 and 20, 17 between 21 and 30, 21 between 31 and 40, 13 between 41 and 50, 7 between 51 and 60, and 4 over 60 years. In 47 of his cases no cause could be given. In 17 cases exposure was given as the cause, but in many cases the history was very indefinite. Injury was said to be the cause in 8 cases. Twenty-five were from surgical cause and 3 were accidental. One seemed to be caused by removal of an ear, another was from a foreign body in the middle ear, a third from an injury of the lower jaw and a fourth from the removal of a tumor from the front of the ear. Another case was caused by the injection into the jaw of an iodoform oil emulsion for an injury. He thinks that injury is not so common a cause of paralysis as the text-books would have us believe. Great stress is laid on the neuropathic tendency. One case was due to injury by forceps. The symptoms were not very marked, sometimes a slight pain; sometimes the sight is affected; sometimes the hearing.

Dr. JOHN C. BLOODGOOD spoke of a surgical operation in connection with some of those cases, and of the difficulties of avoiding the nerves in some operations.

Dr. THOMAS McRAE then made a

REPORT ON 150 CASES OF CANCER OF THE STOMACH IN THE MEDICAL WARDS OF THE JOHNS HOPKINS HOSPITAL.

These were 150 cases of primary cancer, except three, which were secondary. Generally the diagnosis was made postmortem. He referred to the age of these cases; six were between 20 and 30 years, one 22, one 24, two 26, and two 28; seventeen were between 30 and 40 years; thirty-eight between 40 and 50; forty-nine between 50 and 60; thirty-six between 60 and 70, and four over 70 years. Of the latter (between 60 and 70), twelve were male and twenty-four female; 131 white and 19 colored. The proportion of the colored in the Johns Hopkins Hospital being seven white to one colored. In eleven cases there was a family history. Thirty-eight had tuberculosis involvement, but there seems to be no connection between the tuberculosis and the onset of the disease. As to habits, seventy-seven used alcohol, eight excessively, sixty-six moderately and three very slightly. Thirty-three complained of dyspepsia, seventeen had had attacks of acute gastritis, eleven had chronic stomach trouble; five came to the hospital complaining of trouble dating one or two years back. Ten had no complaint of stomach trouble at all. Others complained of pain and vomiting and showed the presence of the tumor. The method of onset was also marked. In thirty-nine cases the onset was rather sudden; twenty-six had notice of disease in three months, eight between three and six months, and eight over six months. He then gave statistics of the time and place and manner of diagnosis.

Dr. JULIUS FRIEDENWALD then read a paper on "Latent Cancer of the Stomach." There are two varieties of latent cancer: 1. Those cases in which the gastric symptoms are absent, or so masked by other general symptoms the gastric disease is not suspected. 2. Those cases in which there are no symptoms. The pathologic conditions leading to latency are the position of the growth at neither orifice and a surface not ulcerated. He reported an interesting case.

Dr. OSLER said that he had seen so many cases of cancer of the stomach since he had been in Baltimore that he was almost inclined to think it was a peculiarity of this region. Dr. McRAE also discussed this paper.

Dr. JOHN C. HEMMETER's paper entitled, "The Pathogenesis and Treatment of Gastric Hyperacidity," was then read by title.

Dr. R. TUNSTALL TAYLOR exhibited several children showing "The Necessity of Post Operative Treatment of Congenital Clubfoot." He emphasized especially that after the child's clubfoot had been operated on the proper instrument should be used and the child looked after until the muscles and other parts should regain their normal condition. Many persons

operate and expect results at once. He also showed several very ingenious instruments for holding the muscles in place.

THIRD DAY—MORNING SESSION.

Dr. HARRY FRIEDENWALD exhibited cases of "Excision of the Ossicles for Chronic Purulent Otitis Media, with Demonstration of Patient." The serious nature of these cases has been recognized, and the rule now is to give the flow of pus every opportunity to escape. The cavity of the middle ear being very small and irregular, containing small bones and bands and membranes, is difficult to drain. In these cases the walls of the middle ear or the attic became carious, and the patient, 16 years of age, came to this condition as a result of diphtheria. He had pain in the ear and, on examination, a large polypus was found reaching beyond the outer opening and the auditory canal. This was removed and afterward the ossicles were removed, on account of caries, and the polypus was curetted. After this the case went on to recovery and the patient is doing well except that he is very slightly deaf.

Dr. THOMAS H. EMORY of Taylor, Md., then reported "A Case of Suppurative Appendicitis; Operation Followed by Fecal Fistula." A colored man, 24 years old, upon whom he operated for appendicitis under most unfavorable circumstances and with the most unhygienic surroundings. The case went on to recovery, there being only a small fistula remaining. The interesting features of this case were: 1. Absence of chills at any time; 2, a moderate range of temperature and the character of the pulse; 3, the symptoms, which two or three days before the operation seemed to be subsiding; 4, at the time of the operation the abscess was apparently ready to break, the walls being extremely pliable in places; 5, the absence of any tumor or fluctuation.

Dr. JOHN D. BLAKE congratulated Dr. Emory on his success in the operation, and spoke of the difficulty surrounding it and also of the necessity of relieving such cases by operative means as early as possible.

Dr. J. W. CHAMBERS then gave a

REPORT OF A CASE OF STAR WOUND IN THE ABDOMEN; EXHIBITION OF THE PATIENT.

The patient was a man who on January 25 had been stabbed with a case or table knife, at the penitentiary, by one of the convicts. There were two abdominal wounds, one to the left of the median line and extending through the abdominal muscles and the omentum, cutting the transverse colon for three inches. There was also a transverse incision through the small intestines. After these injuries the man walked a hundred yards, the intestines protruding, and one hour later was brought to the hospital, and twenty minutes after that was operated on. The intestines were washed, put back and sewed up by Lembert's interrupted sutures, the other wound was treated as an open wound and was more in the region of the liver. There was prompt recovery. The fact that the intestines protruded probably kept the peritoneal cavity free from any contamination. It is interesting to show how much injury can be done to a man in this way without bad results, and then it is also well to note how important a rapid operation is, for within an hour after the injury this case was operated on. He is now apparently well and able to attend to his work, and did not suffer very much from the shock.

Dr. JOHN MORRIS, who is on the Lunacy Board of Maryland, spoke of the man who did the stabbing. He said that in many of these cases who were confined in institutions where there was no work, there came a wave of insanity over them once or twice a year. This man was detained in an insane asylum, and seemed so much better that he was brought to the penitentiary where he stabbed this man, one of the keepers.

Dr. JOHN C. BLOODGOOD then read a paper on "The Transplantation of the Rectus Muscle in Operations for the Cure of Certain Cases of Hernia." The important point to be recognized at the operation is that the conjoined tendon is either obliterated, very narrow or very attenuated; that the lower angle of the inguinal canal has lost its support and therefore something must be substituted for it. He divides all his cases into two large groups: Those cases in which the conjoined tendon is wide and firm and those in which it is practically completely obliterated. Impressed by the large proportion of recurrences in the few cases in which the conjoined tendon has been obliterated, Dr. Bloodgood has devised, and in eight cases performed, a plastic operation in the rectus muscle, bringing this down and so suturing it as to form a support. The procedure is a very simple one. The method of operation is about the same as that followed by Halsted. On inserting the deep sutures, the sheath of the rectus is divided in the direction of the muscle bundles from its insertion through the symphysis pubis, upward for a distance of 5 cm. After the division of

the sheath, the outer border of the muscle bulges out, but may be held back by sutures. The deep silver wire sutures are then inserted as Halsted described. During the last few months the operation has been performed several times in the Johns Hopkins Hospital.

Dr. SAMUEL T. EARLE, Jr., then made some remarks on "Rectal Medication by Means of Collapsible Tubes." There has always been a great difficulty in applying ointments and suppositories in diseases of the rectum. Allingham had devised hard rubber tubes, which were well enough in chronic cases, but rather expensive to use for short use in acute cases. A well-known firm had devised compressible, collapsible tubes, such as painters use, with a long nozzle, and he has found that these tubes, being made of definite size, could be filled with ointments according to the prescription desired, and applied with great certainty and exactness. He used them exclusively. Dr. Earle also gave an "Exhibition of Electric Light for Rectal Work," which was very much on the same order of the electric light for throat work, a combination of the bulb and tongue-depressor. The whole instrument, together with the storage-battery, costs \$10, and is portable and easily handled. One charge will last ten hours, so that the physicians using it for examination through the day need not have it charged very often, and those living at a distance from the city could have the cells sent to them as they were exhausted.

Dr. HUGH H. YOUNG read a paper on

A BACTERIOLOGIC STUDY OF CYSTITIS AND URINARY INFECTIONS; A PRELIMINARY REPORT.

He said this work had been begun about two years ago at the Johns Hopkins Hospital, and was extremely interesting though very hard to carry out. The object was to see, in cases of cystitis, what organisms could be found in the bladder, and his method of making examination was by suprapubic puncture of the bladder, to get the cultures. This was done with every antiseptic caution. The bladder is always easy to be reached above the pubes even when nearly empty, by compressing the abdominal walls. He spoke of the bladder walls in posterior urethritis. It is strange that the bladder is not affected by specific urethritis, but this is rarely the case. It is only when there is a wound of the bladder walls that infection takes place. In eighteen cases of acute cystitis which he had had, the staphylococcus pyogenes albus was obtained in eight cases, and in several it was after the use of instruments. In one case, a young man, 18 years old, had specific urethritis and was treated in the proper way at the hospital, and apparently cured. He was sent home to continue his treatment and, through some faulty technique, returned with cystitis. On examining the contents of the bladder, as above stated, he found the same organism as in the other case. This continued for two weeks but the man recovered. In another case, a German, 50 years old, who was rather fond of beer, one night drank an unusually large quantity and the next day showed symptoms of cystitis with some hematuria. Here the staphylococcus pyogenes albus was again found. The man had never had urethritis and no instrument had been used on him. In five of these cases there was nothing found. Melchior held that the bacillus coli communis was the most common cause of inflammation in the bladder, but this is not the cause of acute cystitis. Some organisms seem to produce a mild attack and some a severe attack of cystitis, and in long continued cases the colon bacillus seems to drive all the others away. These conditions have not been explained. He had also found cultures of gonococcus in gonorrheal rheumatism, and Dr. Thayer in one case had even found organisms in the blood.

Dr. WM. B. CANFIELD said that the work which Dr. Young had described was most elaborate and he thought that the physicians ought to be very grateful to him for bringing it out so clearly. In the case of the German above mentioned, he thought it rather strange that the organisms should be found simply from the beer and from no external cause. He also thought that five sterile cases in so few was a very large proportion.

Dr. YOUNG replied that these organisms may find their way to the body through the blood, and these are paralleled in other internal cases. He was also surprised that five cases were sterile, but he had done his work with great care and was satisfied that he was correct.

Dr. HIRAM WOODS then read a paper entitled "A Case of Congenital Purulent Ophthalmia with Sloughed Cornea." This case was brought to him by another physician and the sloughed cornea was evidently the result of ophthalmia of the new-born. He had followed, as he always did, Credé's method, and in all cases this method should be employed.

THIRD DAY—EVENING SESSION.

Dr. WILLIAM T. COUNCILMAN, Shattuck Professor of Path-

ologic Anatomy at Harvard University Medical School, delivered the Annual Address on

EPIDEMIC CEREBRO SPINAL MENINGITIS.

He said it was only within recent years that we have been able to distinguish, in epidemic cerebro-spinal meningitis, a definite disease produced by a definite etiologic factor. An organism which may be distinguished by certain characteristics of its own has been found in the inflammatory exudation in certain cases of meningitis. This organism may be grown in suitable cultures, and the pure culture, when inoculated into susceptible animals, produces the disease, and this disease follows a regular recognized course. There was a great deal of confusion at first by mistaking this disease and its organism for other diseases and other organisms. What is needed now is a series of sufficient number of cases in which the meninges have been examined during life so that the different types of the diseases may be more sharply defined. The first description of what is now known as this disease was made by Vieusseux in 1805. An epidemic of cerebro-spinal meningitis occurred in Medfield, Mass., in 1806, later other epidemics occurred in various parts of this country. This disease affects principally the young. It may be carried by infected clothing and in various ways. It is commonly called brain fever. There is little in the literature on immunity from this disease. The organism which we now recognize as the specific cause of this disease was first described by Weichselbaum in 1887, and was confirmed later by Jäger, in 1895. It is a micrococcus of about the same size as the ordinary pathogenic micrococci and appears in diplococcus form as two hemispheres separated by an unstained interval. It stains by any of the ordinary stains for bacteria and is decolorized by the Gram method. He then described at some length its manner of growth on various media and its effect on animals.

In the postmortem examinations made it is usually found, and its situation varies according to the stage of the disease. Besides the meninges of the brain and the coverings of the spinal cord, the organisms was found in no other places in the body. The spleen was often enlarged. There were described three forms of the disease, the acute, the chronic and the intermittent. Pneumonia is often a complication but it must not be supposed as it was once thought that the pneumococcus is a cause of meningitis. The surest way of making a certain diagnosis is by lumbar puncture and this should always be carried out when possible. The method is easy and experience has shown that it is devoid of danger.

FOURTH DAY—MORNING SESSION.

Dr. FRANK D. SANGER read a paper "On the Importance of the Early Recognition of Enlargements of the Pharyngeal Tonsil," in which he dwelt especially on this trouble in young children and spoke of the symptoms and bad effects if allowed to continue.

Dr. EDWARD M. SCHAEFRER spoke of the utter ignorance of the laity on such things and how they should be instructed on the dangers of allowing a child to go unoperated on when it gave every evidence of a large growth of adenoids filling the posterior pharynx.

Dr. WILLIS OSLER said that the profession was also to blame and he thought that the profession at large needed education on this subject just as much as the laity. He sees every year eight or ten cases of serious trouble resulting from negligence on the part of the physician who should have insisted on the parents having the child submit to an operation at the hands of a specialist. It is a very easy matter. A child that breathes with open mouth and snores in its sleep should be at once put into the hands of a specialist and it is not every specialist in nose and throat who can treat such cases properly.

Dr. H. O. REIK then made some remarks on "A Further Study of the Use of Formaldehyde in Sterilizing Instruments," and exhibited the small oven devised by himself and Dr. Watson and showed the ease and thoroughness with which instruments could be sterilized. He had taken knives and wiped them across virulent structures and put them in this oven, where the gas thoroughly sterilized them in ten minutes. A five grain tablet burned in the lamp will sterilize the knife in ten minutes and when the instruments are wrapped in a towel they are sterilized by a thirty-grain tablet in twenty minutes.

Dr. WILLIAM R. STOKES of the City Health Department, and Dr. Arthur Wegefarth, then demonstrated "Free Leucocytic Granules in the Blood and their Reaction to Various Stains."

The following officers were then elected for the ensuing year, which will mark the completion of the one hundredth continuous year of the existence of the Faculty: President, Samuel

C. Chew; vice-presidents, Drs. Mary Sherwood and J. McP. Scott; secretaries, Drs. J. Williams Lord, Robert T. Wilson, W. Guy Townsend and H. O. Reik; treasurer, T. A. Ashby.

Ninth International Congress of Hygiene and Demography.

This Congress convened at Madrid, April 10, with all the European governments well represented, except Russia and Denmark, many delegates from Mexico and South America and some from the United States. The 900 Spaniards raised the total number inscribed to 1600, which included six Turks, three Chinese and ten Japanese. The fear of war troubles kept so many away, however, that only 700 were present at the opening, according to the *Munch. Med. Woch.* The government and individuals were "considerate and hospitable and made the Congress a brilliant social event, remarkable under the circumstances," while the presence of many noted hygienists insured its scientific value, although the ten sections and six languages rendered it somewhat difficult to follow all the proceedings. The most important communication was from Nocard of Paris, who announced that he has succeeded in isolating

THE GERM OF CATTLE PLEURO-PNEUMONIA.

It is scarcely visible, even magnified 1600 diameters, and its exact shape, etc., are still undetermined, but biologic and pathologic phenomena prove unquestionably the presence of the culture-making specific germ in the barely visible turbidness of the liquid culture-media. Spronck of Utrecht, stated that he has reduced the percentage of post-sero-therapeutic accidents from 15 to 4 per cent. of the cases treated, by heating the serum in a water-bath to 50 degrees C. for half an hour, which seems to destroy toxic matters in the serum without affecting its antitoxic properties. He also stated that he had obtained a toxin twenty times more powerful than usual by using yeast in his culture medium. One kilogram of ordinary yeast is boiled with five liters of water and then set aside, and after the addition of an alkali, sugar and peptone, is sterilized and filtered. The toxin attains its maximum power on the sixth day. This yeast solution is harmless in hypodermic injections. Martin has shown that the serum varies with the peptone, and Llorente urged the Congress to establish an international standard for serum, and a committee was appointed to investigate the subject. Krause thinks the serum varies with the horse used and that certain persons are more susceptible to post-sero-therapeutic accidents than others. Calmette reviewed the

PRESENT STATUS OF IMMUNIZING AGAINST SNAKE VENOM,

observing that the anti-venom serum is by far the most powerfully active of any serum yet produced. The venom of the poisonous reptiles of the different countries in the world is all extremely similar, and an animal immunized against a very active venom, such as that of the naja or bothrops, is thereby rendered immune to all other venoms less active than the one with which he has been vaccinated. The serum of horses vaccinated against large doses of very active venoms possesses a preventive and curative power to such an extent that its injection confers upon other animals an absolute insensibility to any kind of venom. The amount of curative serum required to save a venom-intoxicated animal is inversely proportionate to its weight and directly proportionate to the quantity of the venom. The antitoxic action of bile, cholesterin, antitetanus and antirabic sera recently reported, is nothing specific, but merely the transient effect of cellular stimulation. He concluded by describing some recent tests, which showed that the anti-venom serum still manifests its curative power even if the nervous system be intoxicated with another strong toxin, such as strychnin. Ermenghen called attention to the fact that even the spores of the bac. botulinus are killed by exposure to a temperature of 85 degrees C., and that the bacillus will not grow in a medium containing more than 8 per cent. sodium chlorid.

DIPHTHERIA IN MAN AND IN FOWLS

was compared by Terré, who considered them closely analogous, as is shown by the fact, among others, that anti diphtheria serum cures both. Isolation is evidently the prophylactic measure required. Loellier objected to these conclusions, as he considers that diphtheria in pigeons differs from diphtheria in fowls, and that the specific toxin of a certain diphtheria bacillus requires an equally specific antitoxin. Professor Chantemesse reported the favorable results on man of his

TYPHOID ANTITOXIN SERUM,

and convincing experimental results. Typhoid antitoxin must neutralize both the microbe and the toxin it secretes, and he has succeeded in accomplishing this since his discovery of the

soluble typhoid toxin which is rapidly produced in certain media and vanishes later with equal rapidity under the influence of the oxygen of the air. The *Presse Méd.* of April 13 contains his communication *in extenso*. He notes the peculiar fact that acidifying a fatal dose of toxin with tartaric acid will deprive it of almost all its toxic power, but that this returns, although not quite to its full extent, if the former alkaline reaction is restored by adding the necessary amount of sodium. Loeffler announced that he had succeeded in rendering animals immune to "aphthous fever," foot and mouth disease, by inoculating them with the active substances contained in the blood of other animals inoculated with the serous fluid from the blisters of animals affected with the disease. This preventive effect is enough to protect a herd against an epidemic of the disease, although the vaccination is only temporary and the actual germ of the affection has not yet been discovered, probably on account of its infinitesimal proportions. Borrel's communication in regard to

CEREBRAL TETANUS AND ITS TREATMENT

is a plausible explanation of the failures in tetanus antitoxin treatment to date. By injecting the tetanus toxin directly into the cortex he produced a special kind of tetanus, quite different from the usual manifestations and varying with the cellular group injected. He proclaims also the important fact that if the antitoxin is injected directly into the cerebral substance a very small amount will save the animal more than fourteen hours after the tetanus has appeared, at a period when even enormous doses injected subcutaneously are without effect. In regard to immunity, this cerebral tetanus demonstrates that it is never the nerve-cell that is rendered immune: in all cases immunity, either natural or acquired, depends upon the arrest of the toxins before they have invaded the sensory cells. Immunity, therefore, is not a question of the nerve-cells becoming accustomed or insensible to the toxin. Behring observed in reference to tuberculosis toxin that he has found birds much better subjects for this kind of research than mammals. He also mentioned the complete cures obtained in cattle with tuberculin treatment, and the satisfactory results if 90 per cent. are cured, even if a few are undoubtedly killed by the treatment. But of course this argument can not be applied to man, as if serum treatment jeopardizes even a single human life it is impracticable. He also urged the importance of an international standard and control over toxins of this kind.

Next congress convenes at Paris in 1900.

Chicago Medical Society.

A regular meeting was held May 3, with President Henrotin in the Chair.

Dr. RICHARD DEWEY read a paper entitled

REMARKS ON THE RELATION BETWEEN MENTAL DISORDERS AND SURGICAL OPERATIONS,

in which he reported forty-four cases of insanity occurring after surgical operations.

In the discussion, Dr. FRANK BILLINGS mentioned the case of a man that came under his observation in 1881. The patient ran a pitchfork into his foot, shortly after which tetanus developed. The sciatic nerve was first stretched and following it the anterior crural, without any good results. Following these operations insanity developed.

Dr. DANIEL R. BROWER said that when iodoform was first used he saw several cases of insanity following iodoform dressings. He believes that the mental derangement was produced by the toxic effect of the iodoform. In introducing new dressings into surgical work their possible effects on the nervous system should be carefully considered by surgeons.

Dr. CHRISTIAN FENGER mentioned a case of insanity following operation for the removal of carcinoma of the lower lip. He thought the disfigurement following the operation was what caused the patient to become mentally depressed.

Dr. A. H. FERGUSON had seen mental disturbances following operations as well as insanity. He spoke of the relationship between septic intoxication and mental disturbances following operative interference. The first case of mania he saw in consultation followed a perineorrhaphy in which there was a great deal of puerperal sepsis.

Dr. A. J. OCHSNER mentioned a case of acute septic peritonitis which he saw eight years ago following a ruptured pyosalpinx or appendiceal abscess. Before the operation the patient was sound mentally, but when she came out from under the influence of the anesthetic she was insane, had to be transferred to an insane asylum, but at the end of two years her mental condition was greatly improved. He cited other cases.

Dr. HAROLD N. MOYER said surgeons had neglected the nerv-

ous conditions of their patients, being quite content if operations were successful.

Dr. ARCHIBALD CHURCH had come professionally in contact with two thousand or more cases of insanity, and yet he was unable to recall a single case in which the operation *per se* could be attributed as the inciting cause of the insanity.

Dr. M. L. HARRIS summed up the causes of insanity following operations, as drug intoxications; septic intoxications; auto-intoxications, from disturbances of nutrition and defective elimination following operative interference; withdrawal of accustomed stimulants, such as alcohol and morphin, and the anesthetic.

Dr. ARTHUR D. BEVAN had seen a number of cases of traumatic insanity following injuries received in railroad accidents.

PRACTICAL NOTES.

Drainage Tubes are used by Delagenière, made of nickel perforated throughout, with a wide rim to prevent its escaping into the wound. A cotton wick inside absorbs the fluid like the wick of a lamp, and ensures perfect drainage.—*Sem. Méd.*, April 6.

Sodium Saccharinate is claimed to be one of the best intestinal antiseptics known to date, without secondary effects. One gram once or twice a day will notably diminish the number of bacteria in the intestines, especially the bac. coli. Take in wafers or in Apenta water.

Cure of Paralysis of the Palate by Electricity.—Six applications of static electricity to the region of the sternomastoid and trapezium stimulated the spinal nerve to such an extent that it cured the existing paralysis of the left half of the soft palate; patient a tabetic.—*Sem. Méd.*, April 20.

Substitution of Trephining for Lumbar Puncture.—Moty relieved a threatening case of acute meningitis by trephining the right parietal region and opening the dura mater, inserting a horse-hair loop and suturing the skin. The pain was relieved at once and all the symptoms gradually improved.—*Sem. Méd.*, April 13.

Eosinophilous Cells in Tuberculous Sputa are evidence that the organism is rallying its forces to repel the invasion of the infection and that it is still resistant. As the infection progresses and bacilli commence to appear, the eosinophilous cells are no longer found.—*Munch. Med. Woch.*, April 12.

Substitution of Salt Solution for Antiseptics in the Treatment of Venereal Buboës.—Waelch announces that buboës injected simply with salt solution heal more rapidly and completely than if mercurial or other antiseptics are injected, which retard the healing process by the irritation they produce.—*Sem. Méd.*, April 6.

A Handy Diabetograph has been devised by Coulhon, which is merely a graduated tube tapering to a point at one end, provided with a faucet. The tube is filled to 0 with urine, which is then cautiously dropped into the boiling Fehling solution, by quarter drops, and the figure at the which the urine then stops indicates the amount of glucose to the liter.—*Bull. de l'Acad. de Méd.*, March 29.

Catgut and Silk Rendered Perfectly Antiseptic by Dipping in Formalin Gelatin.—The gelatin dissolves in the tissues and the formalin thus liberated acts as a powerful antiseptic. Catgut thus treated is less rapidly absorbed. Tests with animals and over a hundred patients confirm the thoroughness of the antiseptics thus secured.—Thomalla: *Munch. Med. Woch.*, April 19.

Temperature of the Eye.—Galezowski's thermometer for the eye fits closely over the ball with the graduated tube bent at right angles. He thinks that the information thus derived in regard to the temperature of the eye will be found useful in certain internal diseases of the eyes, such as chorioiditis, chorioidal hemorrhage, glaucoma, etc.—*Wien. klin. Rundschau*, April 3.

The Improved Local Anesthesia suggested by Oberst (*vide JOURNAL*, page 736) has been applied to operations on the penis with perfect success. Arendt mentions that his patient kept on smoking his cigar while a para-urethral fistula was being thermo-cauterized. He has also operated on phimosis, without assistance after five minutes' local anesthesia.—*Cbl. f. Chir.*, April 16.

Prognathism Cured with Removal of Condyles.—Jaboulay describes a distressing case of progressive prognathism in which mastication and articulation had become impossible, entirely cured by the removal of one condyle, the esthetic results perfect with the exception that the jaw twists slightly to one side, the patient not wishing to allow the removal of the other condyle which would have completed the intervention.—*Presse Méd.*, April 9.

Treatment of Epilepsy by Resection of the Superior Cervical Ganglia of the Sympathetic.—Chipault calls attention to the benignity of these operations, of which there are now seventy-one on record without a single operative incident or accident. The success obtained is very encouraging, although old, inveterate cases are less liable to be favorably affected. The *Bulletin de l'Acad. de Méd.* contains his two latest observations, both successes, one a child of 2½, the other a woman of 33 years.

Orthopedics of the Brain is the term applied by Berillon to the application of hypnotism and suggestion in the treatment of morbid impulses and habits and defective psychic development. He states that in his experiences with several thousand children he has found that eight out of every ten children between 8 and 15 years of age are susceptible to hypnotic influence, adding that susceptibility increases with mental capacity. Taptas also reports nasal troubles caused by vasomotor disturbances in the nasal muscles, cured by suggestion.—*Münch. Med. Woch.*, April 19.

The Success of Injections of Phenic Acid in Tetanus is confirmed again from Rome, where Professor Baccelli's treatment has been applied in thirty cases with one death. The *Gazzetta degli Osp. e delle Clin.* of March 13 compares the statistics on record, omitting all cases of tetanus in the newly born, and finds that with the Baccelli method the mortality is 1 to 30, with Tizzoni's serum 8 to 40, with Behring's serum No. 1, 4 to 11, and with Behring's serum No. 2 it is 2 to 9. The phenic acid is injected in a 2 to 3 per cent. solution, in doses of three-quarters of a centigram, as much as 35 centigrams being injected during the twenty-four hours, in some cases without inconvenience.

The Connection between Otitis Media and Articular Rheumatism is emphasized in a recent communication by E. Bloch, to the *Münch. Med. Woch.*, who says that instead of consulting the barometer and weather-vane, we must set to work, after administering the usual sodium salicylate or other remedies, to locate the local infective process from which proceeds the intoxication producing the disease. It may be found in the tonsils, in a boil, eczema, lacerations in the cervix, etc., but in fourteen out of fifteen cases he has traced it to otitis media. Extermination of the foci, healing all solutions of continuity, this is the only rational prophylaxis against recurrence, and a strict examination is the physician's duty now in the new light of the infective character of the affection.

Therapeutics of Children's Paralysis.—Transplantation of the tendons in a case of spastic cerebral paraplegia. A. Eulenburg reports a success beyond all expectations in a case of Little's disease in which he performed the operation suggested by Nicoladoni sixteen years ago, and only recently taken up and applied to paralytic deformities of the foot by Vulpis and others. The Achilles tendon was cut and part inserted in a slit in the tendons of the peroneus longus and brevis. Each foot was operated separately; patient a girl of 4 years. He calls it a grand "physiologic operation, as it restores function

and nutrition to rigid parts, by centripetal stimulation causing an intercentral liberating process in that region of the cerebral cortex which controls the antagonistic-tonic innervation."—*Deu. Med. Woch.*, April 7.

Lead Nitrate for Ingrowing Nail.—A strip of cotton should be worked in between the nail and the flesh, left large enough to cover the entire nail. A piece of cotton is then twisted into a long roll and placed on the other side of the nail groove over the sound skin. The space between is filled with lead nitrate heaped up, and the larger piece of cotton folded over it, with more cotton outside held in place with a moist bandage. This dressing is renewed every day and in two or three the exuberance will be found reduced until the edge of the nail can be seen and cotton inserted between it and the flesh beneath, when the nitrate can be discontinued.—*Sem. Méd.*, March 30.

For Intravenous Injections of Mercury the cyanid is preferred: 1 c.c. of 1 gram cyanid to 100 grams distilled water, usually introduced at the bend of the elbow after a rubber tube has been tied around the member above, the ends held with a clamp. The needle inserted in the vein is inclined toward the root of the member and pushed in another centimeter. It is then unscrewed from the syringe to note, by the flow of blood, whether it is really in the vein. The syringe is then replaced, the rubber tube removed and the injection proceeds. The patient feels nothing but the first prick. Druault states that neither thrombosis nor embolism have ever been observed and that the intravenous method is no more dangerous than the subcutaneous for the same solutions.—*Presse Méd.*, April 9.

Altitude Cure for Anemia.—Professor R. Lepine concludes a comprehensive study of this subject with the conclusions that mountain air like sea air promotes the formation of hemoglobin by improving the nutrition, but besides this, by some still inexplicable mechanism, it in itself determines a rapid formation of red corpuscles. This hyperglobulia is not permanent in healthy persons, as the number of corpuscles returns to normal in a few weeks after they return to the lowlands. Other things being equal, it seems to be more lasting in anemics than in healthy persons, but even if it is temporary, the stimulation of the hematopoietic organs can not fail to benefit the patient. It is a crisis which may interrupt or at least retard the course of the chronic disease.—*Sem. Méd.*, March 10.

Necessity of Early Antitoxin Treatment of Diphtheria.—P. Hilbert reports the results of much research and experimentation at Königsberg in regard to the dangers of mixed and secondary infections in diphtheria, in the *Deu. Med. Woch.* of April 14. He finds that the streptococcus and the diphtheria bacillus enhance each other's virulence, that cultures flourish particularly well associated and that diphtheria antitoxin has no effect after septicemia has developed. The streptococcus has been found by Reiche in the internal organs of 45.2 per cent. of the diphtheria necropsies and by Dahmer in the blood and spleen in 47 per cent. Hence the necessity of commencing antitoxin treatment at the first indications of diphtheria infection, before the streptococcus has had time to get in its work and increase the virulence of the diphtheria bacillus and be reciprocally affected. The antitoxin changes the diphtheritic lesions into an ordinary diphtheroid angina; the opportunity for the streptococcus to develop increased virulence is lost, and the danger of complications notably reduced. "Theory and practice harmonize so perfectly in antitoxin treatment, that the time is approaching when a death from diphtheria will be among the rarities." We note in the same issue some statistics showing that the average number of deaths from diphtheria per one hundred thousand inhabitants in the German cities from 1886 to 1895 was 106, while since 1895, the average is 44. Also that there were only 274 deaths from diphtheria at Paris in 1897, while in 1886 there were 1524, in 1890, 1639, and in 1893, 1262.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,

No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, 100 Washington St., Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

SATURDAY, MAY 21, 1898.

THE INFLUENCE OF LOCALITY ON DISEASE.

It has only been within a few years that the medical profession in general has come to appreciate the value of the study of natural surroundings in relation to their bearing upon disease. Not long ago hygiene in its true scope was an unheard of study even in the best of medical schools and it has only been very recently that an examination of the medical student upon this part of medical science has been insisted upon by the best faculties in the United States. In England, on the contrary, much more attention has been given to this subject and the government, in a paternal fashion, exercises a certain amount of oversight over hygienic matters which in this country are, unfortunately, too often ignored.

The graduate in medicine of many years ago looks upon hygiene as simply a study of the purity of the air, the purity of water, the principles of isolation and the other general prophylactic measures for the prevention of disease. All of these are without doubt of the greatest importance to the practicing physician, yet there are deeper and wider themes for study in connection with medical geography than many of us appreciate. It is odd that so little attention has been given to medical geography, although the difficulties and cost of competent investigation into the relation of geographic situation to disease have, of course, been effective obstructive agents. It is true that certain localities possessing peculiar health-giving properties have been studied, but these spots on the earth's surface are like oases in the desert of general ignorance concerning the relation of geography to disease. In this connection an article recently pub-

lished by MASON in the *British Medical Journal* of March 12, 1898, is of very considerable interest. He finds, in regard to malignant disease, that cases suffering from such lesions tend to group themselves chiefly about low-lying land in the neighborhood of sluggish streams and where the soil is poorly drained, and he even goes so far as to state that the nearer the stream, the greater the frequency of malignant disease, and he cites specific instances in different parts of England where the percentage mortality from malignant disease is very high as compared to that in the neighboring district where the land is better drained. Or to speak more directly, the percentage of mortality in the upland districts is only one-seventh of that in one of the low-lying districts, and he also quotes NOEL as stating that in "cancer regions" one of two conditions prevail, either they are closely populated, or, if the houses be spread about at some distance from one another, they are connected by a sluggish stream.

Dr. MASON goes so far as to suggest that the malignant disease is due to a microparasite, which he thinks is a protozoon, which gains its entrance into the body in much the same manner as does malaria from exhalations from water or from sodden soil.

These studies of MASON are of particular interest in view of those of Mr. ARTHUR HAVILAND, published in a book entitled, "The Geographical Distribution of Diseases in Great Britain," in which he shows that geographic position governs the mortality of diseases to an extraordinary degree. Thus, in relation to malignant disease he finds that the highest mortality in England is in those areas which have a clay formation and the lowest in those areas characterized by the presence of the older rocks, that the "cancer fields" of England and Wales are chiefly to be found in the shallow, low-lying valleys traversed by full and occasionally overflowing rivers, and that the limestone areas have the very lowest mortality.

In regard to heart disease, HAVILAND finds that those parts of England and Wales which are most exposed to the force of the sea winds are characterized by almost continuous groups of low mortality, and wherever the axis of the valley is identical with that of the prevailing winds a low mortality is observed. On the other hand, when the axes of the valleys are at such an angle to the prevailing wind as to prevent an overflow of air, the mortality from heart disease is very high and the interesting additional information is given that in Devon, England, such areas are incapable of a wheat yield above twenty-one bushels per acre, whereas the average for England and Wales is about twenty-nine bushels.

In view of the fact that many cases of heart disease arise from rheumatic attacks and that cold and damp are supposed to be particularly favorable to the development of rheumatism, these statements in regard to the geographic influences which bear upon

heart diseases are of considerable interest, but it is particularly in regard to the prevalence of cancer that such studies possess novelty to many medical readers. It is to be regretted that with the generous appropriations which have been made by the United States Government for various studies in connection with the public health this matter of the influence of geologic formation upon the development of disease has not as yet been more carefully studied.

THE "AURA" OF EPILEPSY.

The "aura" of epilepsy is so notable a symptom that it is a little remarkable that it has not been more often the special subject of medical writing. It sometimes practically replaces the attack; or perhaps one ought rather to say, the aborted attack does not progress farther than the aura. It is a transitory condition of sensation or sometimes of feeling or intellection or even of motor disturbance that often varies only slightly from the more continued pre-epileptic states in point of duration, and this alone ought to suffice to suggest a greater importance than is commonly attributed to it, on other grounds than merely as an indication of the cortical initial excitation or the peripheral irritation that gives rise to the attack. In some cases it may be itself so annoying and prominent that, when as occasionally happens, the motor symptoms are aborted it is considered as a serious ailment by the patient or his physicians. A homeopathic doctor some years ago wrote a little book on "A New Form of Nervous Disease" which from his description was apparently nothing else than one of these aborted epilepsies in which the epigastric aura ascended to the head and the possible momentary disturbance of consciousness was described as an explosion within the cranium. Such phenomena are common enough to have come under the notice of almost any observant person who has had an extensive experience with epileptics and are by themselves hardly considered as noteworthy enough to call for special mention. It is strongly suggested by some of the phenomena of migraine that it may be properly considered as an aborted epilepsy, the sensory aura blending with the post-epileptic discomfort to form the migrainous attack. Indeed we can not restrict the aura to simply fleeting or momentary conditions, and the attack of migraine itself, however long it may last, may be altogether analogous and parallel to the other types of sensory aura. In a recent paper on this subject Dr. L. PIERCE CLARK of the Sonyen epileptic settlement, makes no special limitations of time for the continuance of the phenomena of the aura; in his view it would seem that any mental or emotional state as well as any set of sensory or motor symptoms, lasting it may be, for hours, and followed finally by an epileptic attack, is to be considered as an aura.

There is, however, a certain practical convenience

in distinguishing between these continued pre-epileptic conditions and the aura in a more limited sense, and as it is commonly recognized. Otherwise we are liable to confuse with it all the conditions that are usually known as pre- and post-epileptic, the *petit mal* attacks and the epileptic equivalent, and there are good clinical reasons for not desiring this to be done. It is better to confine the term "aura" to the sensory and occasionally the motor symptoms immediately preceding the attack either by a few seconds or at most a few moments, and thus restricted the phenomenon is such as to still be worthy of careful study and investigation. The current medical opinion that by it we can at least assume the cortical region in which the morbid process takes its rise, though this be, as CLARK suggests, only the detonating fulminate that starts the explosion, is enough in itself to indicate this importance. In cases of traumatic epilepsy the aura suggests itself, therefore, as to some extent an aid to physiologic localization, and in cases not traumatic we may possibly have in this symptom some indication for rational surgical or other treatment. Before it can be thus utilized, however, more knowledge must be obtained as to the symptoms, and we need more careful and prolonged observations covering a large series of cases. Such studies are not always practicable or easily made, for several reasons. The symptom, except when it involves the motor organs, is a subjective one, as Dr. CLARK points out, and all the fallacies of human testimony have to be reckoned with in estimating the patients' statements. Only close and long-continued observation and repeated examinations, taking into account every possible factor of error and self-deception, and the mental capacity of the subject, his reliability and suggestibility have all to be considered. Again it is only by a large series of such observations that we will ever be in a position to make deductions and there are comparatively few who are likely to be in a position to observe epileptics so extensively as to warrant generalizations. The co-operation of many observers is desirable and these ought to have such special training as will make their observed facts reliable and really valuable for the purpose. Still another possible difficulty is the mixed and sometimes variable nature of the aura itself, which may involve several cortical centers, and is by no means always constant in the same individual. It does not always follow that with traumatism of the brain causing epilepsy, the aura corresponds with the part directly injured, or with the motor symptoms of the attack itself. All these facts complicate the study, but they do not by any means impair its value, and it is highly desirable that it should be thoroughly followed out. Difficulties in such investigations are suggestive rather than discouraging and often are the direct cause of widening the scope and of leading to new discoveries.

Besides the aura there is another well known fact

that is related in a manner to it, and that deserves observation and study. In a very large proportion of epileptics, either with or without an aura, the convulsion begins in definite motor regions, in an arm or leg or in the muscles of the face. A close observation of the facts of the attack itself in as large a number of patients as is possible is also a desideratum if we are to learn all that is within our possibilities of this disease or syndrome of cerebral disorder. Hitherto for the reasons given, this has not been done to any great extent, and it is to such establishments as those that have been recently opened in several States of our Union for the care of epileptics, that we must look for the elucidation of this and other important questions that have been before the medical profession, or will yet arise, in regard to the interesting phenomena of epilepsy.

MEDICAL ORGANIZATION FOR WAR SERVICE.

Recruiting is in progress to fill up the ranks of the regular army to its war footing of over 60,000 men, and as we write, about one-half of the number of volunteers called out by the President have been mustered into service. Brigadier-generals and major-generals with officers for staff duties have been appointed and the regiments will soon be aggregated into brigades, divisions and army corps. Military officers are well satisfied with the appointments, for as a rule they have been made from the list of trained soldiers; and army medical officers also have reason to be satisfied, as five appointments to the position of chief surgeon with the rank of lieutenant-colonel have been given to majors of the medical corps. The work immediately before these chief surgeons is the organization for field service of the medical and hospital force of the army corps to which they may be assigned. Instructions for the guidance of these officers have no doubt been considered by Surgeon-General STERNBERG, but so far nothing of the kind has been made public. So long as a regiment constitutes a separate command the regulations applying to posts or military stations suffice for its medical administration; but a broader working scheme is required when regiments become the units of a larger force.

Additions to the personnel of medical and hospital force are appearing daily in the camps. For the troops of the regular army the law has provided a medical staff and a hospital corps, the strength of the one fixed by law, of the other discretionary with the Secretary of War, except as regards the number of hospital stewards, which is restricted to one hundred. A bill has, however, been introduced into Congress to remove this restriction. For the troops of the volunteer force the act approved April 22, 1898, "to provide for temporarily increasing the military establishment in time of war," authorizes the muster into service of a chief surgeon for each corps, division and brigade, and a surgeon and two assistants for each

regiment, but no mention is made of a hospital corps. Nevertheless, in the act approved April 26, 1898, the main object of which was to increase the regular army to meet conditions of war, there is a proviso authorizing one hospital steward for each battalion, *i. e.*, three to each regiment of volunteer troops. Existing law is thus seen to provide medical officers and hospital corps men for the regular army, and medical officers and hospital stewards for the volunteer army; but no specific provision has been made for the muster in of private soldiers for the hospital corps of the latter. In some of the States hospital corps men of the National Guard have volunteered and been mustered in as privates of the line. These men look forward to transfer hereafter into the hospital service; but at present the only legally defined way into this service is by enlistment into the hospital corps of the regular army. It may be taken for granted, however, that in one way or another a sufficiency of men will be enlisted for hospital duty by the time the regiments have been organized into divisions and army corps.¹

In the organization of the medical staff and hospital force for war service full account must be taken of the experience gained by army medical officers in the many sanguinary engagements of the civil war. That experience demonstrated the incompetency of a regimental medical service and the excellence of a medical organization based on the division as a unit. The regimental medical officers and the regimental hospital are efficient in the summer encampments and ordinary State police duties of the National Guard, just as the post-surgeon and its assistants in the post hospital suffice for the army garrison in times of peace. But in war the medical strength of an army must not be tied up in regimental bonds. It should be a well organized and well disciplined force which, like the reserve of the fighting men, may be brought in its full strength to that part of the line where its services are most required.

The medical force of an army corps should be organized by divisions so that any regiment in the division may have the benefit in times of stress of the medical services and supplies provided for all the regiments. The division consists of three brigades of three regiments each, aggregating 10,000 men. The hospital should consist of thirty to forty hospital tents, with light cots or litters, mattresses and blankets for at least two hundred patients; medical and surgical supplies and kitchen outfits for the campaign; subsistence stores for men and forage for horses and mules for so many days, and the personal baggage of officers and men all packed, when in column of march, in twelve to fifteen six-mule army wagons—and the packing of these wagons should be such that there should be no need to unpack the whole unless the whole medical strength of the division is to be called into action.

¹ Since the above was written arrangements have been made for the transfer (voluntary) of enlisted men of the volunteer army to the hospital corps.

The ambulance company should consist of two hundred privates, with the regular proportion of stewards and acting stewards as non-commissioned officers aggregated in three sections each under a lieutenant, and the whole commanded by a captain. This company should have a train of forty to fifty ambulance wagons. The best officers of the division should be assigned to duty with the hospital, one as surgeon in charge, one as executive officer and recorder, one as subsistence officer, the captain of the ambulance company, acting as quartermaster, and one as attending surgeon for each brigade section of the hospital; but these sections should have no claim to be regarded as brigade hospitals, they being merely wards of the division hospital, although so organized as to be susceptible of being detached at any time with a section of the ambulance company for independent service. Hospital stewards and acting stewards are assigned to special duties under these officers, with privates for pioneer work, cooking, nursing, etc. As thus organized the division hospital carries the sick during the day's march and provides for them in camp, medical officers remaining on duty with their regiments having merely to meet emergencies and care for slight cases which require neither transportation nor hospital treatment. This organization must be prepared for battle-field conditions by standing orders assigning three surgeons as chief operators with three assistants to each of them. Medical officers not thus specially assigned for battle service give first aid at the advanced stations. An organization of this kind can not be broken in for service in a day or two, even supposing that there is no delay in providing all the articles of the equipment. Time is required for every officer and man to become familiar with his special duties under the new conditions. There is in fact much to be done in the way of organization and drill before the medical service of an army such as is now being formed can be ready for efficient service; but as we have earnest men and experienced officers we may rest assured that the Army Medical Department will not be found wanting.

MEDICO-MILITARY STATISTICS.

In September, 1894, an International Commission of Military Medical Officers met at Budapest to consider the best method of tabulating the statistics to be published for comparative purposes by each of the countries participating in the convention. Besides Dr. JOHN S. BILLINGS, who represented the United States, there were present representatives of Britain, France, Germany, Austria-Hungary, Belgium, Denmark and Italy. A series of ten tables was agreed upon, copies of which were submitted to the various military medical departments for adoption, if approved. On suggestions made by the Surgeon-General of the United States Army the ten tables were reduced to eight. The Commission at a subsequent

meeting recommended that the statistical data for the calendar year 1895 be the first to be officially published on the approved forms. The United States acted promptly on the recommendation of the Commission, for as all the data needful for the construction of international tables were already on file in the office of the Surgeon-General of the Army the statistics of 1894 were published in the "Annual Report" for the year ended June 30, 1895. Regularly since then the international tables have formed part of Surgeon-General STERNBERG'S "Annual Reports"; but not until the present time, so far as we are aware, has any of the European medico-military departments issued its statistics on the forms approved by the Commission. In a supplement to the Army Medical Department Report for the year 1896, just published, the data relating to the health of the British army are submitted in a series of seven tables. These correspond with the forms published by the United States authorities; but there are some important omissions, as the prevalence of sickness at the larger garrisons and the prevalence of important diseases by branches of the military service and by months. A comparison of the sickness among our troops and those of Britain, as shown by these tables, is given in another part of this issue of the JOURNAL.

CLUMSY FORGERY.

We were astonished some time since to see in the journal called *Printers' Ink*, in the number of April 27, the name of this JOURNAL printed in a list of publications that had accepted an advertisement of a concoction which we had positively refused to advertise. The following letter is self-explanatory:

"APRIL 30, 1898.

"Editor *Printers' Ink*, No. 10 Spruce St., New York, N. Y.

"Dear Sir: In your issue of April 27, in an article referring to medical journals, you mention the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, and also publish a letter purporting to have been sent by us, to the effect that ——— advertisement would be accepted by our pages. There is an error in regard to this matter, as we did not answer the letter of inquiry from the Rowell Agency, owing to the fact that on a previous date we had declined the advertisement of ——— and had given our reasons therefor. Probably you have the name of this publication confounded with that of another, as the rates quoted do not conform with ours at all. If the letter you have on hand is signed as having come from this office, we would like very much to see the original copy. Please publish a correction of this in your next issue, and oblige."

Receiving no reply to this communication, we waited until May 7, when the following letter was sent registered:

"Editor *Printers' Ink*, New York, N. Y.

"Dear Sir: A careful perusal of your issue of May 4 fails to indicate any notice being made of my communication sent you on April 30, relative to the injustice done the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION in your issue of April 27, regarding this JOURNAL offering to accept an advertisement of ———. Neither have we received a reply to our letter. While we fully believe that you had no intention of doing us an injury in printing a letter as having come from this office, when in

reality we had nothing to do with it, yet we are unable to understand why you remain silent in this manner. We herewith enclose a stamped envelope and respectfully request an early reply."

On May 11 we received the following reply and an enclosure from The Geo. P. Rowell Advertising Co., of which we publish a fac-simile.

"New York, May 9, 1898.

"Editor of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION: We have your registered letter of May 7, addressed to *Printers' Ink*. The reply to our letter of inquiry, concerning the advertising of ———, is enclosed herewith.

"Very respectfully,

[Enclosure.] "THE GEO. P. ROWELL ADVERTISING CO."

to us, you should have *Printers' Ink* publish a correction of this matter. Herewith we enclose a stamped envelope for reply."

It will be noticed that this blank is not signed by anybody. Furthermore the figures inserted in handwriting are not in the handwriting of any person of this office, and those inserted by typewriter are by a green copying ribbon, whereas blue is the color used by the machines of this office. Besides it is noticed that this Company have not returned any rate card. The rate card of the ASSOCIATION is published with the JOURNAL's name and address in plain print and it would have been perfectly easy if they had such a card

Cable Address "Tenspruce,"
Telephone Call "Cortlandt 220."

NEWSPAPER AND MAGAZINE ADVERTISING

New York, Mar. 31, ——— 1898

Publisher of Journal of the Am. Medical Ass'n.,

Chicago, Ill.

*Advertisement acceptable
at \$30 a month \$2.50 a year.*
Dear Sir:— *Must state our four four lines of text paragraph.*
The Ripans Chemical Co. is considering the advisability of advertising

in your paper. Kindly advise us upon the following points:—

FIRST: Will you insert the enclosed advertisement as written? — Yes

SECOND: If it is not acceptable in its present form, what changes do you require? — None

THIRD: What is your price for one insertion in space of copy, or in space of a full page? — \$30.00 — see rate card enclosed,

FOURTH: What is your price for inserting the same one year, every issue, copy to be changed at will, but always subject to your approval? — \$250.00

Please state whether your figures are subject to the usual agent's commission. — yes 30% discount

Very Respectfully,

The Geo. P. Rowell Advertising Co.

P. S. What is the size of a page? How many columns to a page? 5 1/2 X 9-1/2 in.

An answer on this sheet would serve every purpose.

The following letter was sent:

"Your favor of the 9th inst. enclosing a letter from which the editor of *Printers' Ink* published an extract as having been sent from this office, is at hand. In reply we will state that the letter you forwarded to us never came to this office, furthermore the rate, discount and size of paper do not correspond with that of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION. The letter states 'See rate card enclosed,' and we now have to ask that you kindly forward that enclosure so that we may be able to trace the sender. In the meantime, in justice

to have sent it. We are forced to conclude that the whole matter is a "clumsy forgery," and we beg our contemporaries who have been so radical in criticising the JOURNAL to make the necessary correction.

Since writing the above, we have received the following letter from The Geo. P. Rowell Advertising Co.:

"New York, May 14, 1898.

"Editor of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION:— Your letter of April 11, is at hand, in which you ask

us to have published in *Printers' Ink* a correction in a certain matter, about which there has been correspondence between us. We think, if you will be good enough to prepare and send us the matter you think should appear in *Printers' Ink*, we shall have no difficulty about the insertion. If there has been any harm done we regret it exceedingly, and will do all we can to set the matter right. We are, your obedient servants,

"THE GEO. P. ROWELL ADVERTISING CO."

KENTUCKY STATE MEDICAL SOCIETY.

The forty-third annual session of this society was held in Maysville, May 11, 12 and 13, and on account of the location of the town the attendance was not up to the usual standard. The work done however was interesting and instructive.

The President in his annual address made reference to the waning interest and attendance which had been manifest in the State meetings for several years, and suggested the cause as being due to the large number of county, local and district societies, which are attended in preference to the larger body. As a remedy he suggested a modification of the constitution, making a membership in the State society dependent on membership in the county society, the latter naming delegates, in proportion to their membership, to the State society and to the AMERICAN MEDICAL ASSOCIATION. Delegates to the latter from the county societies are recommended to the State society and their selection confirmed by that body. A member of the Nominating Committee for the ensuing year is also named by each county society. This is a radical change in the present arrangement for election of officers, it now being that each congressional district elects its representative, the President appointing a Chairman.

As an instance of the success of this plan, the President referred to the Indiana State Society which now has a membership of 1500.

A committee consisting of Dr. H. E. TULEY, J. N. McCORMACK, and JOHN. A. LEWIS was appointed to consider the matter, and returned a modification of the constitution as suggested.

Dr. H. E. TULEY of Louisville offered resolutions condemning the CAFFREY Bill on public health, and endorsing the bill prepared by the AMERICAN MEDICAL ASSOCIATION, and urging the senators and representatives in Congress to work against the CAFFREY Bill and for the AMERICAN MEDICAL ASSOCIATION Bill. He also offered the following:

It has been brought to the attention of the Kentucky State Medical Society, at Maysville, Ky., in meeting assembled this 11th day of May, 1898, that there is a bill now pending before the United States Congress relative to the suppression of vivisection in all its forms, be it

Resolved, That we, the Kentucky State Medical Society, fully realizing and deeply appreciating the great achievements in the domain of medicine and surgery which may be directly attributable to a practice of legitimate vivisection in the past, and feeling that its suppression as called for by the said pending bill would be a most serious blow to research in the future, do most heartily condemn the passing of such a bill: and be it further

Resolved, That a copy of these resolutions be spread upon the records of the society and that a copy be sent to each representative of the United States Congress from this State, and also to the senators from Kentucky, and an autograph letter from the Secretary of this Society urging them to use their influence to defeat the passing of this bill.

The President for the ensuing year is Dr. DAVID BARROW of Lexington, Louisville being selected as the next place of meeting.

THE AMERICAN MEDICO-PSYCHOLOGICAL ASSOCIATION.

The fifty-fourth annual meeting of the American Medico-Psychological Association which occurred last week at St. Louis, was a success in all respects. The character of the papers read was high and the critics of American psychiatry would have found little in the proceedings to justify their strictures. The annual address by a distinguished neurologist, Dr. ESKRIDGE of Denver, on "The Mutual Relations of the Alienist and Neurologist in the Study of Psychiatry," offered a picture of the future institution for the insane, which if not immediately realizable, will certainly afford a sufficiently elevated ideal for the aim of the present workers in the field. The presidential address also of Dr. BUCKE on the need of more attention to gynecologic surgery in the insane was a thoroughly progressive one, though all may not fully share his opinions. The hospital idea of the asylum was well to the fore in the papers and the discussions, some of which were of very decided interest.

The local arrangements were almost perfect and greatly contributed to the success of the meeting. While there were not any very extensive social diversions beyond a drive around the city, visiting the various points of interest, this was felt by all to be no disadvantage, as the scientific interest in the meetings kept up to the very end. The session was a creditable one to its members as a scientific body, and to the committee of arrangements, who left nothing undone that could contribute to its success.

THE JOURNAL SPECIAL TRAIN TO DENVER.

The JOURNAL SPECIAL TRAIN will leave the Union Depot, Adams and Canal Streets, Chicago, Saturday, June 4, at 11 P.M., via the Chicago, Burlington & Quincy Railroad, arriving in Denver Monday morning 7 A.M., in time for the meeting of the American Academy of Medicine, the American Medical Editors' Association and other medical organizations holding sessions on Monday.

Pay no attention to statements other than those announced in the JOURNAL. The reason for arranging for the stop-over on the return trip was owing to the fact that the Exposition at Omaha will be in much better condition then than now. Passengers from the East taking the JOURNAL SPECIAL at Chicago may have their stop-over arranged without extra cost.

The "Special" will run through. Tickets will be

good for thirty days. The rate will be one fare and \$2 for the round trip, the most favorable rate yet granted the ASSOCIATION.

CORRESPONDENCE.

Beware of Temptations!

INDIANAPOLIS, May 13, 1898.

To the Editor:—From the enclosed letter you can readily see what temptations await us at the Denver meeting:

Editorial Rooms of *The Denver Republican*.

WILLIS S. THOMPSON, City Editor.

DENVER, COLO., May 10, 1898.

Dear Sir:—Will you please send us, by the earliest mail convenient, a good photograph of yourself? We wish to secure it as far in advance of the June Convention as possible, and we will guarantee its return in good condition.

Yours very truly,

WILLIS S. THOMPSON, City Editor.

P. S. Kindly write full name and address on back of photo.

If our fellow members yield to this pernicious way of advertising themselves in the newspapers our ASSOCIATION must eventually become a society of advertising idiots. We have no excuse whatever for this. Quacks have no other way to keep themselves before the public.

Please sound a friendly note of warning through our JOURNAL, and prevent, if possible, our weaker brethren from lending themselves to the practice of vain, miserable foals.

J. L. THOMPSON.

The Stamp Tax and Proprietary Preparations.

BOROUGH OF BROOKLYN, NEW YORK CITY, May 2, 1898.

To the Editor:— . . . Despite the constantly increasing cost of barley, wheat, oats, cod-liver oil, quinin and other commodities, which enter largely into the composition of the maltine preparations, we have decided to bear the tax of four cents per bottle which is to be imposed upon our output, ourselves.

Although this will entail a heavy burden upon us we deem it the duty of every patriotic citizen to contribute cheerfully and without quibbling, such a share of the enormous cost of prosecuting the war as our government may find it necessary to exact.

Yours faithfully,

THE MALTINE COMPANY.

ASSOCIATION NEWS.

The Denver Meeting.

Medical Librarians.—There will be an important meeting of medical librarians and those interested in medical libraries, at the Brown Palace Hotel, Denver, on Monday, June 6, at 4 P.M. HENRY SEWALL, Chairman of Local Committee on Medical Libraries.

Executive or Business Committee.—The first meeting of the Executive Committee of the AMERICAN MEDICAL ASSOCIATION will be held in the club room of the Brown Palace Hotel, Denver, Colo., Monday afternoon, June 6, at 5 o'clock. Subsequent meetings of the committee will be held at the same time and place each afternoon during the meeting of the ASSOCIATION, unless otherwise ordered by the committee. It is essential for the successful conduct of the ASSOCIATION that all the members attend the meetings of the committee. L. DUNCAN BULKLEY, M.D., Secretary.

Railroad Rates.—The Western Passenger Association, Chicago, formally announces the following rates for the Denver Meeting of THE AMERICAN MEDICAL ASSOCIATION, June 7-10, 1898:

Rate.—One regular first-class normal tariff (not temporarily)

fare, plus \$2.00, for the round trip from Association territory to Denver, Colorado Springs and Pueblo, Colo., and return.

Dates of Sale.—Tickets to be sold from Eastern Committee territory, June 2, 4 and 5, and from Trans-Missouri territory, June 5 and 6, 1898.

Limits.—On going trip tickets to be good for continuous passage commencing on date of sale up to first Colorado common point en route; stop-over to be allowed on going trip at intermediate Colorado common points, but to arrive at destination not later than June 7, 1898. The return to be continuous passage beginning on date of execution by joint agent, with the provision that the return passage shall not commence earlier than June 12, nor later than July 6, 1898. Tickets may be executed for return at destination or either of the other Colorado common points en route. Purchaser to commence his continuous return passage return journey from point of execution.

Diverse Routes.—For this occasion tickets may read west of the Missouri River, going one route and returning another via any regularly authorized route via which regular short line one way rates are properly applicable.

Announcement.—The following arrangements have been made for the Denver meeting of the AMERICAN MEDICAL ASSOCIATION:

Section Dinners will be given June 7, at 7:30 P.M., and social entertainments will be given on other evenings during the week.

Ladies' headquarters will be at Unity Church, where they will be received by the wives of physicians of Denver. Arrangements have been effected for their entertainment during their visit, and committees will escort the visiting ladies to the various points of interest in Denver.

On Friday June 10, a complimentary excursion to Idaho Springs and around the loop will be given by the Colorado State Medical Society. At Idaho Springs, the ASSOCIATION will be entertained by the citizens.

On Saturday, a complimentary trip will be made to Colorado Springs under the auspices of the Committee of Arrangements. At Colorado Springs the ASSOCIATION will be entertained by the local physicians and citizens. Visits will be made to all points of interest in the vicinity. Arrangements will be made for trips to Pike's Peak and the celebrated mining camp of Cripple Creek at low rates of fare.

At a date to be determined, special trains for Glenwood Springs will leave Colorado Springs via The Denver and Rio Grande Railroad and the Colorado Midland Railroad. Tickets \$5.00, good going via one railroad and returning the other, and for ten days from date of issue.

The trip to Glenwood is one of the most attractive in Colorado, giving excursionists a view of some of the finest scenery in the Rocky Mountains, including Pike's Peak, Ute Pass, the Valley of the Arkansas, Hagerman Pass, Canons of the Roaring Fork and Frying Pan, Canons of the Grand and Eagle Rivers, Tennessee Pass and the Royal Gorge of the Arkansas and passing through the cities of Pueblo, Leadville, Canon City and Florence.

Special Hotel rates will be given by the Hotel Colorado and other Hotels of Glenwood Springs. The springs, baths and swimming pool will be free to the ASSOCIATION.

Special cars will be hauled on the Colorado Springs train and the Glenwood Springs Special, only when handed to the railroads with their full capacity.

Section Dinners.—The following Section Dinners will be given at the Denver meeting of the AMERICAN MEDICAL ASSOCIATION on Tuesday, June 7, at 7:30 P.M.:

Practice of Medicine, Metropole Hotel.

Surgery and Anatomy: Obstetrics and Diseases of Women; Ophthalmology, Brown Palace Hotel.

Laryngology, L'Imperiale Hotel.

Materia Medica, Pharmacy and Therapeutics; Cutaneous Medicine and Surgery, Windsor Hotel.

Diseases of Children, The Albany Hotel.
Neurology and Medical Jurisprudence, University Club.
Stomatology, St. James Hotel.

In order that satisfactory arrangements may be made for dinners, it is essential that all members who expect to be present notify the Chairman of Committee on Section Dinners as soon as possible and not later than June 4.

E. C. RIVERS, Chairman,
16th and Stout Sts. Denver Colo.

Hotels.—The following is a list of the principal hotels of Denver with the rates agreed upon for the meeting:

The Brown Palace Hotel, 17th Street and Broadway. Take 17th Street (red) car to Hotel. European plan, \$1.50 per day and upward.

The Windsor Hotel, 18th and Larimer Streets. Take 17th Street car to Larimer Street. American plan, \$2.00 per day; room with bath, \$2.50 per day.

The Albany, 17th and Stout Streets. Take 17th Street (red) car to Hotel. American plan, \$2.00 to \$3.50 per day.

The Markham Hotel, 17th and Lawrence Streets. Take 17th Street car to Hotel. European plan, \$1.00 per day and upward.

All reservations at the Albany and Markham must be for the full term of the Meeting, and be paid for whether occupied or not unless canceled ten days in advance. They reserve the right to place persons occupying a room alone in a single room.

The New St. James Hotel, Curtis near 16th Street. Take 17th Street (blue) car to Hotel. American plan, \$2.00 to \$3.50 per day.

L'Imperiale, 14th Street and Court Place. Take Colfax Avenue car to Court Place. American plan, \$2.00 to \$3.00 per day.

Metropole Hotel, Broadway near 17th Street. Take 17th Street (red) car to Broadway. European plan, \$1.00 to \$2.00 per day. \$1.00 rooms, \$1.50 if occupied by two persons. No reservations made.

The Oxford Hotel, 17th and Wazee Streets. Two blocks above depot. European plan, \$1.00 to \$3.00 per day. An extra charge for two persons in one room.

The American House, 16th and Blake Streets. Take 16th Street car to Blake Street. American plan, \$2.00 per day.

The above hotels make no extra charge for reservations or for persons occupying a room alone except as stated.

The Hotel Broadway, Cheyenne Street and Broadway. Take Colfax Avenue car to Cheyenne Street. American plan, \$1.25 to \$1.50 per day.

The Vallejo, 1420 Logan Avenue. Take Colfax Avenue car to Logan Avenue. American plan, \$2.00 per day and upward.

The Devonshire, 14th and Logan Avenues. Take Colfax Avenue car to Logan Avenue. American plan, \$1.50 per day and upward.

The Albert, 17th and Welton Streets. Take 17th Street (red) car to hotel. European plan, \$1.00 to \$1.50 per day.

The Aldine, 1013 Seventeenth Avenue. Take 17th Street (red) car to hotel. American plan, \$1.25 per day.

The Richelieu, 1727 Tremont Street. Take 17th Street (red) car to Tremont Street. European plan, \$0.50 to \$1.00 per day.

The Earl, 1430 Tremont Street. Take Colfax Avenue car to Tremont Street. American plan, \$1.50 to \$2.00 per day.

Glenarm Hotel, Glenarm and 15th Streets. Take Colfax Avenue car to hotel. European plan, \$1.00 per day and upward.

The Bonaventure, 18th and Glenarm Streets. Take 17th Street (red) car to Glenarm Street. European plan, \$0.50 to \$1.50 per day.

The Drevel, 17th and Glenarm Streets. Take 17th Street (red) car to hotel. European plan, .75 to \$1.50 per day.

These hotels make small extra charges for two persons occupying same room. No charge for reservation.

Applications for rooms should be made to the hotels direct. For special information apply to ROBERT LEVY, M.D., Chairman Sub-Committee on Hotels, California Building, Denver, Colo.

J. W. GRAHAM, M.D., Chairman.

W. A. JAYNE, M.D., Secretary.

SOCIETY NEWS.

Texas Medical Association.—At the recent Association meeting resolutions were adopted in opposition to the District of Columbia Vivisection Bill.

New Hampshire Medical Society.—The 107th anniversary of the Society will be held May 26 and 27, 1898, at Concord. Moses C. Lathrop, Dover, president; Granville P. Conn, Concord, secretary.

Indian Territory Medical Association.—The semi-annual meeting of the Association will convene at Wagoner, June 1, 10 A.M., for a two days' session, E. N. Allen, South McAlester, president; LeRoy Long, Caddo, secretary.

American Gynecological Society.—The Society will hold its twenty-third annual session at Boston, Mass., May 24 to 26, Paul F. Mundé, President; J. Riddle Goff, 22 East Thirty-fifth Street, New York, secretary.

West Tennessee Medical and Surgical Association.—The seventh annual meeting of the Association was held at Jackson, May 19 and 20, R. B. Maury, Memphis, president; I. A. McSwain, Paris, secretary.

Kansas State Medical Society.—As previously announced (*vide* JOURNAL, p. 804) the Kansas State Medical Society met in Topeka May 4, 5 and 6. The committee, composed of five members from each of the three State societies, regular, eclectic and homeopathic, decided to hold another union meeting on the first Wednesday in May, 1899. Each committee is empowered by the society it represents to select a representative to read a paper at the 1899 union meeting. The object of these union sessions is the furtherance of medical legislation. The election of officers for the regular Society resulted as follows: President, J. A. Lane, Leavenworth; first vice-president, Melvin Collins, Oxford; second vice-president, S. B. Fairchild; corresponding secretary, J. W. Porter, Litchfield; recording secretary, W. E. McVey, Topeka; treasurer, L. Reynolds, Horton; librarian, S. G. Stewart, Topeka; member of judicial council, M. P. Sexton, Bonner Springs; chairman medical section, G. A. Boyle, Louisburg; chairman surgery section W. C. Bower, Lebanon; chairman gynecologic section, W. H. Smithers, Moline; chairman section on ophthalmology, H. L. Alkire, Topeka.

Wyoming State Medical Association.—Pursuant to a regularly issued call, physicians from various parts of the State met in the parlor of the Union Pacific Hotel, Rawlins, Wyo., May 13 for the purpose of organizing a State medical society. The meeting was called to order and the call read by Dr. E. Stuver, when an organization was effected by electing Dr. J. C. Hammond of Hanna, temporary president and Dr. E. Stuver, temporary secretary. The meeting then proceeded to the consideration of a constitution and by-laws, which, after a free discussion, was adopted, subject to alterations and amendments at the next regular meeting, which will be held in Rock Springs Nov. 1, 1898. The following officers were then elected to serve until the next annual meeting: R. Harvey Reed, president; Jacob W. Hawk, first vice-president; J. C. Hammond, second vice-president; W. C. C. Freeman, third vice-president; E. Stuver, secretary and editor; H. M. Bennett, treasurer. Drs. R. Harvey Reed, E. Stuver and J. C. Hammond were elected delegates to the AMERICAN MEDICAL ASSOCIATION. After the appointments of the committees the society adjourned.

Alabama State Medical Association.—At the recent meeting of the Alabama State Medical Association, a proposition to have a Jerome Cochran lecture delivered by some eminent physician, at the annual meetings in memory of this physician, was adopted. The following recommendations were also adopted. That the next Legislature be asked to adopt a law requiring compulsory vaccination and that the State Health Officer be called in in doubt; that a law be adopted giving the State quarantine laws precedence over the county laws; that the State Board of Health have charge of the matter of controlling the movement of trains, etc., in the event of epidemics; that the location of the proposed monument to Jerome Cochran be changed from Selma to Montgomery. The following officers were elected: President, H. A. Moody of Bailey Springs; orator, G. C. Chapman of Mobile; senior vice-president, S. G. Gay of Selma; junior vice-president, S. H. Lowry of Huntsville; secretary, G. R. Waller of Montgomery; treasurer, H. G. Perry of Greenville. Mobile was chosen as the next place of meeting.

National Confederation of State Medical Examining and Licensing Boards.—The eighth annual meeting of this Confederation will be held in the Brown Palace Hotel at Denver, on Monday, June 6, at 10 o'clock A.M. The following program has been arranged:

Address of Welcome, by William P. Munn, Health Commissioner of Denver. Response by Vice-president William Bailey.

Report of the Committee on Minimum Standards of Requirement; N. R. Coleman, Chairman, Columbus, Ohio. Discussion and action thereon.

Report of Secretary and Treasurer.

Annual Address by the President: Uniformity the Key to Reciprocity.

The results of the Medical Law of New Jersey, E. L. B. Godfrey, Camden.

The Results of the Medical Law of Massachusetts, by E. B. Harvey, Boston.

The Results of the Medical Law of Kentucky, by Joseph M. Mathews, Louisville.

The Tennessee Method, by T. J. Happel, Trenton.

Under What Conditions is the State of Virginia Likely to Reciprocate as to Standards with Other States, by R. S. Martin, Stuart.

Some of the Practical Reasons why Latin and Greek should not be included in the Standard of Preliminary Education Required of Medical Students, by Henry Beates, Jr., Philadelphia. Discussion thereon, by J. A. Egan, Springfield, Ill.

On the Preparation of Questions, by Edward Cranch, Erie, Pa.

Papers by Charles K. Cole, Helena, Mont., and A. Walter Suiter, Herkimer, N. Y.

The object of the Confederation is to consider questions pertaining to State control in medicine and to compare methods in vogue in the several States, the collection and dissemination of information relating to medical education and to consider propositions that have for their purpose advancement of the standards in the United States. A cordial invitation is extended to all members and ex-members of State Medical Examining Boards, and to physicians, sanitarians and educators who are friendly to the objects named, to attend the meeting and participate in its proceedings.

A. WALTER SUITER,

Secretary.

WILLIAM WARREN POTTER,

President.

Florida State Medical Association.—At a recent meeting the Florida State Medical Association endorsed the resolutions adopted at the quarantine conventions held at Mobile and Atlanta, memorializing Congress to take appropriate action for the protection of the United States against the incursion of yellow fever from foreign sources and particularly from Cuba, and adopted the following resolutions, ordering that the action be certified to the Florida senators and congressmen in Washington, urging immediate action:

"Resolved, That it is the sense of this convention:

"1. That Congress be requested to provide for a Department of Public Health as soon as practicable:

"2. That it is the sense of this convention that Congress should enact laws to provide for an efficient maritime quarantine, to be uniform and impartial in its application to the different commercial ports of this country, so as to give no one or more of them undue commercial advantage over the others, and to be enforced by the several State and municipal quarantine or health boards if they will undertake so to do; leaving also to the States the power to prescribe and enforce additional safeguards of the health of their communities, provided that such State action shall not unreasonably obstruct commerce.

"3. That Congress should aid the several States in establishing and maintaining uniform, reasonable, and efficient quarantine laws for affecting, but not regulating interstate commerce, leaving to each State adequate power to protect as it shall deem best the lives and health of its people.

"4. That Congress should leave exclusively to the States the regulation of their purely internal commerce and the provision of such quarantine and sanitary laws and regulations as they may deem advisable to that end.

"5. That in the framing of quarantine laws and regulations, and in their enforcement, Congress should avail itself of the learning, experience and ability of the medical profession in the fullest measure possible, and especially by way of an advisory council."

In connection with the same subject, Dr. Frank H. Caldwell of Sanford, offered the following resolutions, which were adopted unanimously:

"Resolved, That this Association extend its congratulations to their fellow-citizens of the State of Florida upon the escape of the State from an epidemic of yellow fever during the past season, when the dread disease prevailed so extensively in our neighboring States of Alabama and Louisiana.

"Resolved, further, That in the opinion of this Association, our freedom from the invasion of this disease was due to the active work of our State Board of Health and particularly to the untiring zeal of our efficient State Health Officer.

"Resolved, That in our opinion any relaxation of restrictions during the coming season will materially increase the danger of importation of the disease into the State. We, therefore, urge the State Board of Health to insist on the United States Government recognizing this danger and request the Governor of the State of Florida to uphold the State Board of Health in enforcing regulations which they may deem proper to make for our protection."

The election of officers resulted as follows: President, R. P. Izlar of Waycross; first vice-president, T. S. Anderson of Branford; second vice-president, W. L. Hughlett of Cocoa.

PUBLIC HEALTH.

An Abominable Italian Industry.—It has just been brought to the attention of the authorities in Naples that the ragmen have been in the habit of purchasing the wadding or charpie used for dressing in the hospitals, and after washing it, selling it to upholsterers for padding sofas; the railroad cars have also been using this discarded material. A vigilance service has been established to prevent such sales, and this wadding or dressing is now destroyed in the sanitary furnace at Pasconcello.—*Medical News.*

Health in Chicago.—The report of the Department of Health for April gives 2133 deaths for the month, a rate of 1.32 per 1000. The rate for the corresponding month in 1897 was 1.06. Of these 2133 deaths, 505 were persons under 1 year old and 266 between 1 and 5 years. The principal causes were: Pneumonia 359; nervous diseases 276; consumption 222; bronchitis 131; acute intestinal diseases 119; heart diseases 116; typhoid fever 94; cancer 60, and diphtheria and membranous croup 30 cases. There were 135 examinations of suspected diphtheria made, of which 60 were found to be true diphtheria, 69 false diphtheria, while 6 examinations were unsatisfactory, *i. e.*, no growth, etc.

Health in Michigan.—The report of the State Board of Health for April gives the diseases most prevalent during the month as, rheumatism, influenza, neuralgia, bronchitis, pneumonia, inflammation of the kidney, pulmonary consumption and diarrhea. Compared with the March report (*vide JOURNAL*, p. 998), measles and remittent fever increased in area of prevalence. Compared with the average for twelve years, for April, intermittent fever, consumption, scarlet fever, whooping-cough, remittent fever, erysipelas and diarrhea were less prevalent. Consumption was reported at 147 places, measles at 117, scarlet fever 50, diphtheria 43, typhoid fever 37, whooping-cough 19, and smallpox at one place.

The New York Board of Health Provides Against Emergencies.—The Health Department of New York city realizing that conditions may arise during the coming summer requiring the employment of a large number of experts who have had experience in its work, has asked that all persons who have been employed in the department during the past twenty years send their names and addresses to the Secretary at the office, Center and Elm streets. The names thus sent in will be placed on a roll, to be known as the "Reserve Sanitary Corps." It is not stated whether this corps will receive any recompense, if called upon; and it is not stated how the order of selection will be arranged. Is it possible that an evasion of civil service regulations is being foreshadowed?

Decision Favorable to a Contagious Disease Hospital.—In a suit to prevent the maintenance of a smallpox hospital on the ground that it is a nuisance to the neighboring residents of the small Yorkshire town in which it is situated, Justice Romer sitting as an equity judge, lately heard considerable interesting medical testimony in regard to the manner in which smallpox may be conveyed from the patients in such an institution. The complainant's witnesses were generally of the opinion that the disease could be transmitted through the air to some extent,

outside the precincts of the hospital. One witness, however, the government health officer at Hastings, limited the likelihood of outsiders being reached by smallpox to such persons as came within 600 feet. This theory of aerial convection, as it is called, was rejected by the medical men testifying in defense of the Yorkshire hospital, who expressed great confidence that wherever all the facts of a case of smallpox could be ascertained it would appear that the malady was due either to direct or mediate contagion, that is, contact with the patient himself or with a person who had seen the patient. Justice Romer refused to adjudge the hospital to be a nuisance, but did not expressly determine whether the theory of aerial convection is or is not correct.

The Prevention of Smallpox.—Apropos of the history of smallpox in Paris since 1870, there has just appeared a comparison of the conditions which obtain in Berlin and Paris. Vaccination is not compulsory in France, and since 1870 more than 20,000 people have died in Paris from smallpox. There have been two or three noteworthy epidemics, the epidemic of 1871 and 1872 being especially severe and fatal. Berlin has had no epidemic since the one that occurred among the French prisoners in 1871. Vaccination is compulsory in Prussia, and school and military regulations are so framed that care is taken to provide for revaccination later in life, as well as the original vaccination in early childhood. Paris' lowest death-rate from smallpox for any year since 1870 was in 1895, when only seventeen deaths were reported. Of this state of affairs the health authorities were very proud, and not without reason, since the inability to require vaccination makes it extremely difficult to guard against the spread of the disease when once it has invaded a district. The next year, 1896, a few scattered cases of smallpox occurred in Berlin and two deaths were reported. The excitement over this was very great and a whole series of investigations were undertaken to discover, if possible, where the blame lay.—*Medical News.*

Health of Large Cities in 1897.—The European edition of the *New York Herald* contains the following table of mortality in a certain number of towns in all parts of the world during the year 1897. The Hague 14.8, Brighton 15.0, Cardiff 15.1, Amsterdam 15.2, Stuttgart 16.1, Charlottenburg 16.1, Portsmouth 16.2, Christiania 16.2, Bremen 16.3, Frankfort-on-the-Main 16.3, San Francisco 17.1, Stockholm 17.2, Hamburg 17.2, Berlin 17.4, Copenhagen 18.8, Brooklyn 17.8, London 18.1, Paris 18.6, Philadelphia 18.7, Lyons 18.8, Venice 19.1, Leipzig 19.6, New York 19.7, Dresden 20.4, Cologne 21.2, Vienna 21.3, Birmingham 21.5, St. Petersburg 21.8, Glasgow 21.9, Nuremberg 22.5, Halle 22.7, Manchester 23.0, Baltimore 23.0, Aix-la-Chapelle 23.1, Salford 23.8, Liverpool 24.3, Munich 24.5, Breslau 25.0, Stettin 25.3, Belfast 25.7, Trieste 25.8, Dantzic 26.2, Havre 27.5, Rouen 28.4, Moscow 28.6, Dublin 28.9, Madrid 29.8, Cracow 32.3, Bucharest 32.8. It will be seen that Berlin, Paris and London hold a high position. The mortality in Berlin is usually considerably larger, and last year was an exceptionally healthy one in the German capital. In very many of the large cities the rate of mortality in 1897 was much smaller than in previous years. The improvements in sanitary arts are beginning to bear fruit and even better results are expected by those who, under the name of sanitarians, are devoting their lives to the combat with communicable disease.

A Wall Disease Due to Micro-organisms.—Dr. Vallin, before the Ninth International Hygienic Congress, considered the subject of the presence of saltpeter in the walls of domiciles. From this condition, he claims, there results a disease of the walls due to the presence of micro-organisms. As the walls could not suffer without causing serious inconvenience to the persons whom they were destined to shelter, it was the duty of sanitary reformers to seek to cure the walls and thus save the inhabitants. The disease was caused by the penetration

into the body of the walls of the bacilli of nitrification, and consequently the houses became cold, damp and unwholesome. This condition was likely to occur in damp localities and in presence of nitrogenous organic matter. From the sanitary point of view this disease of the walls could and should be prevented or cured as we prevent or cure virulent diseases among men and animals. Consequently, Dr. Vallin proceeded to speak of the walls of a house just as if they were human beings and went systematically through the various symptoms of their diseases. Dealing first with the prophylaxis of wall diseases, he pointed out that the primary step to be taken was to thoroughly drain the ground round the walls and isolate them from the surrounding earth, if possible by a trench and by the use of cement, asphalt, or coal-tar. Thus the access of water-bearing nitrifying bacteria that are aerobic would be prevented. It was also very necessary to mix the mortar used with antiseptic solutions such as dissolved sulphate of copper, etc. Where these precautions had not been taken and the disease had broken out, then the treatment indicated was as follows: First, to scrape off and wash away all superficial traces of saltpeter, etc.; then the walls should be inoculated with active cultures of the anti-nitrifying bacilli which impoverish farm manure by decomposing the nitrates and by throwing off in the atmosphere a great part of the nitrogen which they contain; these walls should then be covered over with impermeable paint so as to retard the process of nitrification of the aerobic germs and, on the other hand, to stimulate the growth of the anaerobic and anti-nitrifying germs which remove the oxygen from the nitrates and from ammonia when they can not supply themselves with oxygen from the atmosphere.

A Pennsylvania State Hospital for Consumptives Proposed.—Dr. Benjamin Lee reports in *Public Health*, March, that progress has been made in regard to the proposed mountain sanatorium for the tuberculous. Several points along the line of the Lehigh Valley Railroad have been visited by Dr. Lee and his coadjutors and White Haven has been found to possess special advantages for such an institution. The point selected is about 1225 feet above the level of the sea, and 150 feet above the Lehigh River. Green Mountain rises gently from the Borough of White Haven until at an elevation of 100 feet above the town it forms a plateau, a few hundred feet in width, stretching westward indefinitely. It is on this plateau that it is proposed to locate the sanatorium. The prevailing winds of this locality are northwest, and the sanatorium would be protected from them by Green Mountain, which rises rather abruptly from the plateau some 400 feet, and passes westward continuously with the plateau. It thus affords admirable shelter from the wind. The sun exposure is all that could be desired. The outlook is to the south and the plateau is bathed continuously with sunshine from daylight to dark. The view is out over a wide stretch of wilderness, east, west and south. From the top of Green Mountain there is a charming prospect toward every point of the compass. The soil is porous, and rains, however slight, are speedily carried down the declivity, or so thoroughly removed by percolation as to prevent the rendering of the atmosphere humid, as it would be under other circumstances. With the exception of a clearing on the plateau, which is occupied as a farm, the mountain side is wooded. It is the natural home of the pine, though the extensive lumbering operations which brought White Haven into being, have long since brought about an almost entire disappearance of this beneficent tree, whose varied products, by some strange chemistry of nature, have ever been found to be so healing in affections of the respiratory tract. For purity of atmosphere the locality is up to a high standard, and is pronounced practically free from miasmatic and malarial influences. This tract of several hundred acres can be had free of cost, if the funds for building and organizing the plant can be obtained. A donation, by the State legislature or by private contributors, of \$30,000 will launch the enterprise. The legislature of 1898 has recently declined to make the appropriation this year, but the movement will not be allowed to rest there.

BOOK NOTICES.

Medical and Surgical Report of the Boston City Hospital.—Ninth Series. Edited by CHARLES F. FOLSOM, M.D., W. T. COUNCILMAN, M.D., and HERBERT L. BURRELL, M.D., Boston, published by the Trustees, 1898. Pp. 276.

The contents of this volume are the following:

1. A Clinical Study of Eight Hundred Cases of Diphtheria at the South Department of the Boston City Hospital, by John H. McCollom, M.D.
2. Heart Complications in Diphtheria, by Cleon Melville Hibbard, A.M., M.D.
3. Acute Degeneration of the Nervous System in Diphtheria, by John Jenks Thomas, A.M., M.D.
4. The General Infections and Complications of Diphtheria and Scarlet Fever, a bacteriologic Study of 157 cases, by Richard Mills Pearce, M.D.
5. Seventy-one Cases of Cerebro-spinal Meningitis, by Francis H. Williams, M.D.
6. Hydatid Cyst of the Liver, by A. L. Mason, M.D., and H. L. Burrell, M.D.
7. Surgical Abstract, by Herbert L. Burrell, M.D., and John T. Bottomley, M.D.
8. The Clinical and Pathologic Report of a Case of Fracture of the Spine in the Cervical Region, by J. W. Courtney, M.D.
9. Treatment of Prolongation Forward of the Nasal Septum into the Nostril, by John W. Farlow, M.D.
10. A Case of Vesico-Utero-Vaginal Fistula Treated by Colpocleisis, by Charles M. Green, M.D.

Report of the Health Department of the City and County of San Francisco. Paper. Pp. 463. San Francisco. 1897.

This report is for the fiscal year ending June 30, 1897, and, in addition to the many full-page tables, contains a map of the city showing localities of deaths from diphtheria, total number sixty-six, during the fiscal year. The reports are largely tabular in form. An appendix contains, a list of master plumbers, markets, laundries, bakeries; reports on samples of food collected; chemist analysis; inspectors' record of milk cases; arrests and disposition of cases, and a report on sanitary condition of dairies and number of cows.

Proceedings of the North Dakota Medical Society, for 1897. Paper, pp. 80. Grand Forks, N. D., 1898.

This volume comprises the transactions of the tenth annual meeting of the State Medical Society of North Dakota, held at Grand Forks, May 26 and 27, 1897, the by-laws, constitution, and list of members. The following papers are included: "Voluntary Commitment of the Insane," "An Interesting Case of

Heart Disease;" "Equal Parts of Chloroform and Ether as an Anesthetic;" "Demonstration of a New Cystoscope for Examination of the Bladder;" "Treatment of Severe Forms of Corneal Ulceration;" "A Method of Treatment for Acute Appendicitis where Pus or Severe Infection is Present; with Report of Cases;" "Résumé of Thirty-six Operations for Appendicitis;" "General Remarks on Typhoid Fever;" "Hemiatrophia Facialis with a Case;" "Ventre-Fixation of the Uterus."

Twenty-first Annual Report of the Board of Health of the State of New Jersey and Report of the Bureau of Vital Statistics. 1897. Paper. Pp. 389. Trenton, N. J. 1898.

This volume contains reports covering the usual matters found in health reports; a list of members of the State Board of Health; list of coroners; "The Public Health Law of New Jersey," by W. M. Lanning; "River Pollution," by E. J. Marsh; circular and laws, "The New Jersey Sanitary Association," and numerous tables of vital statistics.

NECROLOGY.

THOMAS D. DUNN, M.D., West Chester, Pa., died May 6 as a result of an operation necessitated by a recent accident. He was a graduate of Pennsylvania University, 1881, a member of the Philadelphia Pathological Society, Pennsylvania State Medical Society, and, in fact, founder of the Chester County Hospital. He was 44 years of age.

NORMAN GAY, M.D., Columbus, Ohio, died at his home May 6, aged 78 years. During the Civil War, as a surgeon on Grant's staff, he rendered service at Shiloh and Corinth and afterward in the hospitals at Nashville and Atlanta. Dr. Gay was a member of the AMERICAN MEDICAL ASSOCIATION, and one of the charter members of the Ohio State Medical Society.

C. H. EVANS, M.D., Canton, Ohio, died May 12. He was a graduate of Jefferson, 1884, a member of the AMERICAN MEDICAL ASSOCIATION, Ohio State Medical Society, American Microscopical Society and other societies, and author of a monograph on "The Microscope in Diagnosis and Prognosis."

A. L. BROWNE, M.D., Cornwall-on-Hudson, N. Y., May 3, aged 36 years.—Henry Doutteit, M.D., New Britain, Conn., May 3, aged 50 years.—Harold Eagleson, M.D., Meadville, Pa., aged 27 years.—D. McL. Graham, M.D., Wallace, N. C., May 5.—B. M. McCauley, M.D., West Salem, Ohio, May 3, aged 50 years.—John Seay, M.D., Nashville, Tenn., May 9, aged 73 years.—Albert Toon, M.D., Louisville, Ky., May 9, aged 58 years.—Jerome J. Tuthill, M.D., Chicago, May 12, aged 34 years.

DEATHS IN THE PROFESSION ABROAD.—Prof. S. Stricker, one of the medical celebrities of Vienna, a pioneer and author in general and experimental pathology. His death followed a month after the celebration of his twenty-fifth professional jubilee, as also occurred with Prof. E. Schwimmer, the dermatologist of Buda-Pesth, whose death is announced in his 62d year. —P. L. Utinguassu, professor of physiology and anatomy, Rio de Janeiro.—Lazaro Ortega, M.D., Mexico.—Prof. G. Dragendorff, Rostock, author of numerous works on pharmacy, legal chemistry and toxicology.—D. A. Appia, M.D., Geneva, aged 80 years, one of the promoters of the Geneva Conference.—Jules Worms, M.D., Paris, aged 68 years, noted for his contributions to epidemiology and medical statistics.

MISCELLANY.

Election of Professor.—Dr. G. P. Head has been elected Professor of Laryngology and Rhinology at the Chicago Post Graduate Medical School.

Honesty in Advertisements was attempted by a bill before the New York State legislature which failed of becoming a law.

Although not so announced, the measure was intended as a blow against patent medicines, which as usual were abandoned to their fate. Trade requirements were too powerful.

Practice in New Hampshire.—The third examination for licenses to practice medicine in the State of New Hampshire will be held at the State House, Concord, on Tuesday and Wednesday, June 21-22, 1898, beginning at 8 o'clock A.M. All unlicensed physicians who were not in practice in this State on and before March 16, 1897, must pass the examinations in order to receive a license to legally practice their profession. Application blanks should be procured at once, as these papers must be filled out and in the hands of the Regent by June 15. All information regarding the coming examinations will be cheerfully given by the Department of Public Instruction, State Library, Concord. FRED GOWING, Regent.

Importance of Sugar as a Food.—Chauveau recently demonstrated before the Paris Académie des Sciences that the general assumption in regard to the amount of calories produced by sugar is erroneous. Instead of the theoretic assertion that three grams of sugar are equivalent to the nine calories produced by the consumption of one gram of fat, only 0.756 grams of sugar are required to produce this same amount of calories. He urged the repeal of duties which tend to restrict the use of sugar, contending that the people should be encouraged to use it more freely.

Effect of Section of the Spinal Cord on the Bactericidal Power of the Blood.—A series of experiments on dogs, at Catania, demonstrate that cutting the spinal cord destroys the bactericidal power of the serum, which then favors the development of colonies of the anthrax and coli bacilli instead of decimating them as in the normal condition. It was also found that the lesion materially reduced the alkalinity of the blood and the amount of albuminoids contained in it. The animals also lost their normal resistance to these infections and succumbed rapidly to inoculations. It is still a query whether these phenomena are due to the trophic disturbances or the hypothermia which follow the injury to the spinal cord.—*Gazzetta degli Osp. e delle Clin.*, April 17.

Lymphadenoma and Leukemia.—Hallepeau concludes from a rare case he has been observing, that primary leukemia may occasion eruptions simulating mycosis, accompanied by intense pruritus and multiple adenopathy without appreciable alterations of the integument. The subcutaneous tissue may become indurated, thickened and hypertrophied, although the surface remains smooth and the natural contours are retained in spite of the enormous amplification, in his case symmetric, and on the face, producing a most remarkable appearance.—*Ann. de Derm. et de Syph.*, March.

The Tolerance of the Tissues for Wires is strikingly exemplified in a case described by Lucas-Championnière, in which the tripeps and tendons had been ruptured and were so contracted that immediate union was impossible. A double silver wire was passed through the muscle above the capitellum and another through the capitellum itself, thus fastening the solid bone to the solid part of the muscle. The arm was placed in a splint and when the dressing was changed the fourth day, the arm was mobilized. The patient was entirely cured in a month and radiographs taken seven months later showed the complete regeneration of the muscle.—*Bull. de l'Acad. de Méd.*, March 29.

Restoration of the Urethra in Hypospadias.—Nové-Jossierand reports the success of a new operation. He supplied a new skin-lined urethra by taking on Ollier autoplasmic flap from the thigh and rolling it around a piece of a 21 bougie only a trifle longer than the penis, skin side in, tied to the bougie at each end, the edges caught together with a couple of stitches, the whole somewhat resembling an umbrella in its cover. A tun-

nel was first made through the tissues of the penis, commencing at its juncture with the scrotum, and the skin flap was then introduced into this tunnel, the end emerging at the point of a normal urethral orifice. The skin flap soon grew in; the bougie support was removed the tenth day; soft catheters were cautiously inserted the fifteenth day; results perfect; permanent to date, six months.—*Rev. de Chir.*, April 10.

Ants and the Plague.—A Bombay correspondent of *The Times of India*, describes an observation made by him regarding a nest of ordinary red ants, which infests the storerooms in India. The house in which the ants had their nest was infected with plague virus as shown by the number of rats and bandicoots which were daily found dead. One day it was noticed that the ants were moving and taking all their belongings to a new home about nineteen feet from the old nest. Further observation revealed that many hundreds of the insects were dead and dying, that the dead had been carried away by their companions about a foot distant from the new home until a little reddish heap was formed, and that much of the stores of rice had been cast away as if unfit for food. Two days later, the mortality still continuing, a further move was made, the dead ants and the discarded rice being left behind. This performance was repeated several times until an accident destroyed the nest and prevented further observations.

The Frequency and Importance of Vascular Thrombosis in General Pathogenesis is emphasized by Venneman, who states that thromboses are found in the finer blood and lymph vessels wherever there has been an infection. They are not necessarily accompanied by sclerosis nor acute inflammation, nor by especially sluggish circulation. The endothelium alone shows signs of exaggerated vital, pathologic, activity; thinner walls, swollen and divided nuclei. The thrombosis is therefore due to the circulating fluid. It is not caused by microbes directly. He considers the giant cells of tubercles nothing but thrombosed vessels with a crown of exaggerated proliferated epithelial nuclei. Ecchymoses and sarcomas, etc., also contain many thromboses. His principal research was made with ophthalmologic specimens. He concludes with the hope that an effective medication may soon be found to oppose this thrombotic tendency.—*Sem. Méd.*, March 30.

Inference From Removal of Ovaries.—In some cases injuries are sustained which are of such a nature as will, in themselves, warrant an inference that they will permanently affect the injured person's health, or lessen his or her capacity to labor. But the United States circuit court of appeals declares, in *Western Union Telegraph Company vs. Morris*, that it can not say that the injuries inflicted by a surgical operation, which consisted in removing ovaries and Fallopian tubes, were of such a character that a jury was at liberty to infer therefrom that the health of the person upon whom the operation had been performed would be permanently affected, or that her capacity to labor would be thereby impaired. It is just as reasonable to suppose, in the absence of any evidence on the subject, continues the court, that she sustained no loss in either of these respects. On the other hand, the court holds that it was not reversible error to leave the jury to determine whether a telegraph company's failure to properly transmit a message summoning a physician was not the proximate cause of the plaintiff's being subsequently compelled to undergo such a surgical operation, when the physician testified that if he had reached the patient at the time he would have, but for the mistake, he believed that he could have rendered the subsequent surgical operation unnecessary.

Brain Abscess in Infants.—In the *Archives of Pediatrics* for February and March, Holt reports five cases of abscess of the brain in infants and a summary of twenty-seven collected cases in infants and very young children. He concludes that: 1. The affection is rare under five years of age. 2. Otitis and trauma-

tism are the principal causes. 3. It most often follows neglected cases, though rare in acute otitis, and is usually secondary to disease of the petrous bone. 4. In cases in infancy without evident cause, the ears are probably the source of infection. 5. Abscess rarely develops after injury to the head without fracture of the skull, and cerebral symptoms arise within two weeks after the injury in nearly all traumatic cases. 6. Only general symptoms are present in a large proportion of the cases. 7. Unless they are constant, focal symptoms may be misleading, and even when constant may depend on meningitis or other associated lesions. The motor symptoms alone can be relied on. 8. Rapid progress, fever, and history of injury generally diagnostic from tumor, while lumbar puncture assists in slower cases with little or no fever. 9. Where there are only terminal symptoms, the diagnosis from meningitis is impossible. In the more protracted cases the distinctive points are the slower and more irregular course and generally a lower temperature. 10. Operation should not be urged unless definite localizing symptoms, the principal one hemiplegia, are present.

Asphyxia Neonatorum.—Fry (*Am. Jour. of Obstetrics*, April) considers Schultze's form of artificial respiration most efficient, but one that on account of its roughness should not be tried too long. He has had good results with hypodermatic injections of 15 minims of whisky, in some instances the asphyxia being in the more severe state. In the severer form persistent vigorous efforts toward artificial respiration act injuriously on the heart, therefore in infants born in this condition, he leaves the infant undisturbed in its placental attachment so long as any pulsation of the cord is apparent. It should be suspended by the heels for the purpose of clearing the throat and upper air-passages of mucus, and assisting by gravitation to overcome cerebral anemia. From this point the indications are: Application of external heat, best done by immersion in water at 100 degrees F., and stimulation of the respiratory center. the circulation, the muscular system and the abolished reflexes. He recommends strychnia, hypodermically, to fulfil these indications. He administers $\frac{1}{200}$ gr. and carries on accessory treatment after its administration, artificial respiration being carried on while the child is in the hot bath, Sylvester's or Derr's method being best in these circumstances.

Gleanings.—Several cases of acute rheumatic polyarthritis very favorably affected by intravenous injection of corrosive sublimate. *Cbl. f. Therap.*, 1898, 1.—Benefits of thyroid treatment for obesity extolled by Affanassieff; entire absence of trouble or disturbances. *Klin. therap. Wo.*, v, 6.—Incontinence of urine first symptom noted in a case of ovarian cyst. *Jour. de M. de P.*, April 3.—From a study of 100 cases of paralysis agitans, v. Krafft-Ebing is inclined to ascribe the etiology to psychic or mechanic trauma affecting persons undergoing biologic involution, usually during the fifties, superadded to a tendency to perivascular sclerosis. *Wien. kl. Woch.*, xi, 1.—Splenalgia noted in nine-tenths of the cases of chlorosis, also frequent osteomyalgia. Golubov in *Sem. Méd.*, March 30. Case of vulvitis gangrenosa (noma gen.) with diphtheria bacilli, cured with antitoxin. *Deu. Med. Wo.*, April 14.—Five cases in four generations in one family in which acute circumscribed edema developed, about 20 years of age, with intermittent vomiting, colic and other symptoms of an angioneurosis. *Wien. kl. Wo.*, 14.—Bismuth intoxication reported following injection of 35 grams of a 10 per cent. aïrol emulsion into an abscess in the psoas. *Cbl. f. Chir.*, April 23.—Dos Santos states in the *January Gaceta Med. de Bahia* that a case of beri-beri contracted by contagion has never been known in the Brazilian navy.—Pure pneumococcus found in arthritis in the wrist complicating pneumonia. *Sem. Méd.*, April 6.

Total Extirpation of the Bladder.—First performed on man in 1887, this operation has only been successful in three cases to date, all women, reported by Pawlik, Kossinski and Trendel-

enburg. The latter inserted the mouth of the healthy ureter in the sigmoid flexure. The *Rev. de Chir.*, April 10, contains the report of the first success obtained on a man, communicated by Tuffier and Dujarier, date October, 1887. The bladder was the seat of an alveolar epithelioma involving the entire wall. The patient, 40 years, was much emaciated from the extreme pain he had suffered, but otherwise in good condition. Ether. Trendelenburg position. After a \perp incision on the median line of the symphysis, extending to the inguinal region, the bladder was shelled out like the uterus in a vaginal hysterectomy without opening into the peritoneum. The orifice of the urethra was thermo-cauterized, the ureters catheterized and a button-hole made in each side of the rectum, through which the catheterized ureters were inserted, bringing the ends of the long catheters and of the threads that fastened them in the ureters out through the anus and fastening them. Iodoformed gauze was applied first then aseptic gauze and the wound closed except a large subpubic opening left; aseptic cotton dressings. The urine passed off duly by the catheter: there was no vomiting; slight fever a day or two later with pulse 130; restored to normal with intravenous injection of 1800 grams of physiologic solution, repeated 1500 grams next day. Fifth day threads removed; seventh day catheter removed and hypogastric wound drained with tube siphon. A little urine and fecal matter drained out the first day, but after this recovery proceeded uneventfully except for a slight transient edema of right leg. Urine was normal in quantity and the patient now attends to his usual occupations, wearing his reservoir and siphons without inconvenience.

Object of All Questions to Experts.—The object of all questions to experts, the supreme court of appeals of West Virginia says, in the late case of *State vs. Musgrave*, should be to obtain their opinion as to matters of skill or science which are in controversy, and at the same time to exclude their opinions as to the effect of the evidence in establishing controverted facts. Although an expert may have heard all the testimony in the case, he can not, continues the court, be asked to give his opinion, based merely upon his having heard such testimony in the case, whenever there is a conflict therein, unless the same is hypothetically propounded to him. An expert can not be asked to give his opinion on doubtful facts in the case on trial, which remain to be found by the jury, but a similar case may be hypothetically put to him, based upon the evidence in such case. Where the inquiry relates to a subject which does not require peculiar habits of study in order to enable a man to understand it, the opinion of skilled or scientific witnesses is not admissible.

Electric Localization of the Motor Cortical Zone.—The *Archives Clin. de Bordeaux*, vi, 11 and 12, contain a study by L. Lamacq of fifty observations of faradic stimulation of the cortex in man, by such observers as Keen, Allen, Starr, Bechterew and others, over half of them unpublished. He notes that the first movement in response to stimulation has the most significance: the reaction becomes more complex as the effect of the stimulation spreads. The localization is so precise that the slightest change in the position of the electrode affects the response. Precisely localized motor reaction denotes higher functional activity. No simple movement can be obtained in animals nor in the motor zone, for the face and lower members: the reaction is always a co-ordinated movement. He observes that it would be interesting if tests could be made on acrobats and others who have trained their feet to serve them like hands. The inexcitable points seem to be quite numerous, and are located between the excitable centers. The motor zone and the various fissures may vary slightly in different individuals, and morbid conditions may affect the reaction. The extreme utility of faradization as a means of investigation, its importance to surgery and its established harmlessness, should lead

to its more general adoption. In comparing his average diagrams with Ferrier's we notice that the motor zone is confined more strictly to the anterior central convolution. The thumb and eyelid centers alone impinge constantly on the posterior central convolution.

Modern Discoveries merely an Evolution of the Medical Sciences not a Revolution.—The profession is too modest to claim before the lay public all the credit that justly belongs to it, and that should be more widely appreciated. The discoveries of late years have merely confirmed with scientific reasons the methods of procedure adopted as the results of observation and experience long years before phagocytosis and antitoxins were dreamed of. The public is apt to think that the new discoveries have revolutionized everything, while in fact the reverse is the case; they merely explain the why and wherefore of the old methods. A striking instance is shown in the mortality from puerperal fever at the great *Charité* at Berlin during the century. From 1801 to 1813, it averaged 2.06 per cent. of all maternity cases. The physicians in charge at that early day, insisted on cleanliness, refrained from vaginal palpation and used sodium hypochlorite freely, and from 1814 to 1852 the mortality fell to 1.1 per cent. Since Lister's day it has averaged 0.29 to 0.5 per cent. The frightful increase between 1852 and 1874 was due to the increased facilities for the study of anatomy and the students going directly from the dissecting-room to the maternity wards. In those years the mortality averaged one-sixth, while one-third of all the maternity cases contracted the disease. Another instance is the discussion of the value of revulsive measures to which the *Paris Acad. de Méd.* has devoted over half a dozen recent sessions. Huchard claims that the blister has passed away with the seton and other minor dubious therapeutic measures, but the majority are cordially in favor of it still and refer to numberless instances in which, applied with judgment, it has rendered invaluable assistance. One member quoted the Italians, who have shown that the local stimulation is carried all through the lymph and blood circulation. Another mentioned a patient of his who had been relieved each time with a blister, with no injurious after-effects, and had applied it nearly three hundred times.

Studies from a British Blue Book.—Cleveland Moffett, in an analysis of a British Blue-Book statistics of deaths in England during 1890, 1891 and 1892 draws many interesting conclusions. He finds that in a comparative mortality table that the dispensers of alcohol, who head the list, die of its effects from three to ten times faster than the average of occupied males, three times faster for the brewer and ten times faster for the London hotel servant. On the other hand, the mortality from alcoholism among agricultural laborers, railway men, iron and tin and coal miners, clergymen, fishermen and others is far below the average, only one-third or one fourth of it, while in the case of soap manufacturers, lead workers, copper miners and carpet manufacturers, no deaths whatever are recorded from alcoholism. The mortality among publicans in London, according to Moffett is nearly double that of all occupied males for the former class, inasmuch as they die nearly 10 times as fast from alcoholism, 5 $\frac{1}{2}$ from gout, 3 $\frac{1}{2}$ from diabetes, 3 $\frac{1}{4}$ from liver diseases and more than twice as fast from phthisis, rheumatic fever and suicide. Our statistician especially points out also the glossing over of the real causes of death due to alcoholism by a simple statement of a mere pathologic condition. He cites cirrhosis of the liver as a particular instance to the point and suicide as another. In the British Empire as well as in the United States we may add that the sentiment of survivors may have more to do with the pardonable falsification than scientific accuracy. Society in the main contents itself with the penalty of crimes only against itself. Further, the analyst before mentioned betrays a certain animosity toward musicians since in their sad addiction to intemperance they die

more than twice as fast as ordinary men from alcoholism, a little below that average from phthisis and very much more rapidly from liver and nervous diseases and suicide. To the heightened death rate of commercial travelers he gives a passing allusion, despite the mitigation of time spent in the open air. By a between-the-lines reading of the interesting report and a grouping of figures given we may conclude without much effort that our length of days depends upon a variety of environments which we may ourselves control. Our chief regret is that space can not be afforded for discussion of the suicide rates as governed perhaps solely by monotonous employments and the deficiency of occasional excursions outside the groove. Humanity besides a given loyalty to its stomach does not well brook a complete subservience to the practical without a chance of some desirable prize.

Foreign Bodies in the Vagina.—The causative relation of a forgotten pessary to fetid leucorrhea is sufficiently well known. M. Monod of Bordeaux relates some curious experiences he has made on the existence of various foreign bodies giving rise to the same symptoms. In one case he removed from a young woman a sponge which she alleged to have inserted some time previously, in order to suppress an abundant discharge. The sponge was already in a state of putrefaction, and came away in pieces. A rather elderly woman came to the hospital to be treated for fetid discharge. When the finger was passed up it perceived an ovoid foreign body, which when extracted, proved to be a rosebud, in a good state of preservation. The patient pretended to know nothing about it. Last spring he had occasion to examine a woman, aged sixty, of rather limited intelligence, for a double inguinal hernia. For a year before she suffered from vaginal discharge which was so fetid that she had to isolate herself from society. Suspecting the existence of a neoplasm, he chloroformed the patient in order to make a proper examination, and to operate if necessary. When he introduced the hand into the vagina he felt a hard mass which seemed to be independent of the surrounding tissues. Passing a long forceps in he seized the body, and when he drew it he found it was a large cork. Renewing his explorations he successfully removed a thimble, a rag, a needle case, and finally a boot lace. The uterus was perfectly healthy.—*Medical Press and Circular*.

Rapid and Cheap Production of Liquefied Gas.—A recent discovery has been reported in the *Medical News* that promises to have no small future practical interest to those lines of medical, surgical and pathological work requiring the application of cold. Professor Peckham of the Adelphi College of Brooklyn, has made the first public demonstration of the new discovery of Mr. T. C. Tripler of Manhattan, comprising the liquefaction of air. For many years chemists have been searching for the absolute zero. Scientists have been on this hunt with as much eagerness as explorers have been searching for the north pole. The announcement had been made that at 273 degrees C. below zero, 460 degrees F., all heat would cease. About 330 degrees in liquid oxygen had been reached. The first scientists to liquify oxygen did so at a cost of \$2500 a quart. Mr. Tripler has recently discovered a method to produce it at a nominal cost with a forty-horse-power engine. He could make from two to three gallons every hour of a liquid air, which can in this form be drawn out in pipes and can be handled as easily as water. As soon as it comes out it begins to boil violently until the air about it is frozen and cooled, then it ceases to boil. Those present witnessed the novel sight of a mercury hammer. The professor took a handful of fluid mercury and placed it in a kind of mold. This was placed in a pot of liquid air and before it became hard a rod of iron was inserted in the mercury. In a moment the professor drew out what appeared to be a hammer with a silver head. The mercury had become frozen so hard that a nail could be driven with it. Several other

curious experiments were made. Professor Peckham is reported as saying that this discovery bids fair to stand, among the innovations of recent years, second only in importance to that of the Röntgen ray.

Comparison of the United States and British Army Medical Statistics.—In the following comparative statements the figures relating to the Army of the United States are placed in brackets. The first table of the British compilation on the forms agreed upon by the International Statistical Conference shows the number of recruits who were medically examined, with the ratios per thousand accepted, rejected, etc. To fill the ranks of the British army during the year 1896 54,574 [14,659] candidates for enlistment were examined, and of every 1000 of these 576.52 [590.35] were accepted for service. The chief causes of rejection were: Imperfect vision 40.81 [49.87]; varicose veins and hemorrhoids 30.56 [51.65], and under height 28.79 [5.46]. The second and third tables show the strength of the European troops in the various colonies and commands, with the numbers admitted to sick report, died, invalided, constantly non effective, etc. The average strength of the army was 203,145 [23,487], and of every 1000 of these 942.7 [728.24] were admitted to the hospital for treatment; 8.14 [3.66] died; 24.99 [0] were sent home as invalids, and 16.26 [10.15] were discharged for disability. The constant non-efficiency was equal to 60.71 [33.97] per 1000 of strength and the average sick time to each soldier amounted to 22.22 [12.40] days. The highest admission rate was reported from China, 1856.5 [Dept. Platte, 871.96], the lowest from Bermuda, 470.8 [Dept. Dakota, 502.19]; the highest death rate was from India, 15.29 [Dept. Texas, 6.59]; the lowest from Canada, 3.34 [Dept. Columbia, 0.71]; the largest rate of men sent home as invalids was from China, 61.22, the smallest from Gibraltar, 6.48; the highest rate of discharge was from China, 31.29 [Dept. Dakota, 12.29], the lowest from Bermuda, 0.72 [Dept. California, 7.15]; India gave the highest rate of non-efficiency, 93.85 [Dept. Missouri, 37.23]; Bermuda the lowest, 26.86 [Dept. Columbia, 28.78]. The fourth table deals with the various arms or branches of the service and the variations of their rates by months. The infantry had the highest rates: Admissions to hospital per 1000 of strength, 1094.2; deaths, 9.45; constant sickness, 70.80; but in the United States both the artillery and cavalry had higher rates than the infantry troops. The movement of sick by months seems to have little value in a consolidation of commands which includes stations so different in their climatologic factors as the United Kingdom and India, South Africa and Canada. In the fifth and sixth table are given the numbers remaining at the close of 1895, the admission during 1896 and the total treated for certain specific diseases, with the rate per 1000 for each item. The prominent figures in the rates of constant sickness are the following: Bronchitis acuta, 1.09 [0.84]; febris intermittens, 3.52 [1.01]; gonorrhea, 9.15 [3.22]; rheumatismus articulorum, 2.10 [1.22]; syphilis, 14.22 [1.29]; typhus abdominalis, 1.67 [0.88], and morbi cutis, 2.91 [1.83]. Showing in favor of the United States troops is very marked. The seventh table gives deaths from disease, suicide, accident and injury according to age and years of service.

The Outlook in Regard to the Nerve-Cell.—"Cell Therapeutics." The morphologic changes noted in the chromatophilous elements of the nerve-cells of motor nerves in the course of infections and intoxications (*vide* JOURNAL, xxix, page 696), have been found to bear no relation to the functional activity of the nerve-cell. It is, therefore, evident that the fundamental substance of the cell, the part not affected by Nissl's stain, the "between substance," is the essential seat of functional activity. As the morphologic alterations or chromatolysis have been noted with either strychnin or tetanus, we conclude that they are caused by the chemic action of certain groups of atoms in both the toxin and the nerve-cell, between which a

chemic affinity evidently exists. Whether it is a mere coincidence or a matter of essential importance that a hyper-excitability of the nerve-cell accompanies these chemic, morphologic alterations, is still a problem. Ehrlich considers the groups of atoms stored in the cells which "bind" the toxin, identical with the antitoxins (the important results that have already proceeded from this new conception were mentioned recently in the *JOURNAL*, page 449). Whenever the equilibrium of affinities has been established, the cell starts on a process of restitution. If the intoxication was intense and rapid, as in tetanus, the affinity equilibrium is soon established and restitution commenced proportionately early. If it is slow, as in tuberculosis, the binding of the toxin becomes a slow process and restitution is consequently deferred. The problem now before us is to determine the morphologic expressions of the functional activity of the nerve-cell. Another line in which much may be accomplished, is in the study of the reaction of the nerve-cell to peripheral injuries, also the relations between the cell and functionally active groups of muscles, etc. Pharmacologic research in regard to the alterations produced by intoxications should not be confined to a single toxin, but applied to combined, complex intoxications, and to various regions of the central nervous system. It may be possible by histology to determine the affinities and antagonisms between certain chemic substances (morphin and atropin, for instance), and the limits of dangerous doses. These studies may possibly restrict to certain regions and groups of neurons the affinities for various groups of poisons, and we may even progress before long from our present standpoint of the "pathology of the nerve-cell" to cellular therapeutics.—Goldscheider and Flatau in the *Deu. Med. Woch.* of March 17.

Philadelphia.

METHOD TO PREVENT HOSPITAL ABUSE.—For some time past the physicians of this city have been urgently trying to regulate and restrict those who flagrantly abuse the charity of hospitals. Among others who have taken a prominent part in this movement are Drs. John Ashhurst, Edward Jackson, Horace G. Evans and George I. Harlau. A meeting was recently called, at the College of Physicians, to consider means to check the evil. Judge William N. Ashman of the Orphans' Court, presided: Dr. Edward Jackson stated the purpose of the meeting and gave an account of like movements in New York, Boston, and other cities. Dr. J. W. Walk and others cited instances of the evil. Judge Ashman stated that the worst effect of the abuse lay in the demoralization of the public conscience, giving use to habits of pauperization, and suggested as a remedy that patients should be made to make a statement of their means and resources. He thought a new statute would be required to make falsehoods legally punishable. At the close of the meeting the following committee was appointed to keep up the work: Drs. John Ashhurst, John B. Roberts, S. D. Risley and Professor Charles Frese.

MEDICO-CHIRURGICAL COLLEGE WINS ITS SUIT.—According to a decision recently made by Judge Gordon of Philadelphia, certain exceptions made by the Philadelphia Dental College against the Medico-Chirurgical College were over-ruled and the latter can now amend its charter and confer degrees in both dental surgery and pharmacy. The opinion cites: The original act of incorporation empowers the college among other things to establish a department of instruction in surgery (including dental surgery) and pharmacy. The supplementary act of 1867 confers upon the college all the rights, immunities and privileges as to lecturing, granting diplomas and conferring degrees in medicine, possessed by the officers and professors of the University of Pennsylvania at the present time. Further, "why would not this grant of power include degrees in dental surgery and pharmacy? Are not dental surgery and pharmacy branches of medicine? The students in dental surgery are instructed, we are informed, in anatomy, physiology, chemis-

try, therapeutics, materia medica, pathology, etc. Indeed the latter and better tendency is to closely ally both pharmacy and dental surgery to the parent science of medicine and to have the students in all three of these sciences matriculate with the same institution. The growth in the dignity and efficiency of dental surgery is largely due to the fact that the practitioners of this art today unlike their representatives in the past are educated carefully on allied medical studies." "The powers asked for in the amendment now before the court, we therefore think, are already included in the chartered rights of the college, but to make it plainer, the amendment (to charter) asked for is proper and should be allowed. The petition is therefore allowed and a degree will be made accordingly."

GRADUATING CLASS OF JEFFERSON.—According to a resolution recently passed by the members of the graduating class, their services were offered to the government.

DAIRY SUSPECTED OF SPREADING DIPHTHERIA.—The milk furnished by the dairy of Patrick Brady in a suburb of this city was recently suspected of spreading diphtheria to his patrons and chief medical inspector Taylor has been investigating the conditions on the dairy farm. Nuisances were found and until these are abated the farm will be under a strict quarantine. The milk is now undergoing bacteriologic investigation at the Health Bureau.

PHILADELPHIA MORTALITY STATISTICS.—For the week ending Saturday May 7 there were 445 deaths, twenty-five less than the previous week and twenty-nine more than for the same period of last year. Of the total number of deaths there were from diphtheria 22, scarlet fever 7, typhoid fever 7.

Detroit.

AT THE REGULAR MEETING of the Detroit Medical and Library Association, April 25, Dr. J. M. Mathews of Louisville, Ky., read a paper entitled "Extirpation of the Rectum," after which he held a clinic. He believes in the specialty of rectal diseases, and that the rectum is a field in which specialism can be carried out. He deplored the fact that the charlatan is preying on the afflicted and non-afflicted while the medical profession is standing by and looking on. He also wished to take issue with those who reported good results from the so-called American operation on the rectum. On extirpation of the rectum he made the points that only in a few cases should the operation be practiced: 1, those of carcinoma were complicated with hemorrhage that could not be controlled by any other means excepting extirpating the mass; 2, when the infiltration did not involve the surrounding glands; 3, where the pain could not be controlled by opium. He took exception to "Kraske's" method of resection of the rectum, upon which he said that the operation was a lengthy one, that the removal of a part of the sacrum was not necessary, and lastly, that the patient would not live long enough to make the operation an object to the operator or patient. The particular point that he wished to make in his paper was that all cases of stricture could be forcibly dilated, and of the great number he had so operated upon, relief had come to the patient from pain and difficult defecation. Drs. Jenks and Wyman discussed the paper. In the clinic the first patient shown was one that Dr. H. O. Walker had operated on last September, by forcible dilatation. Dr. Mathews examined this patient and commented upon it, saying that the majority of strictures of the rectum were specific, and that if upon examining a patient you find a large mass well up the rectum and it is not cancer, then in 99 per cent. of cases it is syphilitic. The second patient, the Doctor examined and forcibly dilated, after which he curetted, saving all particles removed for microscopic examination. After he had cleansed the field of operation he inserted a rubber tube around which an iodoform gauze bandage had been wound. Attached to the tube was a string which allowed the dresser to keep track of the tube. The Doctor objected to the sponge umbrella of Allingham, because when

used, internal hemorrhage took place, the first signs seen being those of fainting, etc., while with the rubber tubing it can be easily seen when starting. He said the tube was also effective as a means of keeping the parts clean. He says that every disease of the rectum could be diagnosed with the finger, except internal hemorrhoids, and that syphilis, cancer and tuberculosis, on this order, are the most frequent diseases of the rectum. He also said that all fissures in adult men can be cured by dilatation and massage, and gave a history of two cases of young people with carcinoma of the rectum, a boy of 16 and a girl of 17 years. Where there is syphilitic infiltration of fibrous tissue there is no cure for the patient. A tuberculous rectum is more resisting than a cancerous rectum. He has found fissures in children. Dilatation by the mother's fingers anointed with vaselin, once daily for a few days, brought speedy relief and cure. In closing his clinic he said he wished to place himself on record in inoperable cases of the rectum, especially wherever resection was impossible and the pain was great, as feeding his patient opium until the patient had relief, even at the risk of making an opium-eater of his patient.

Dr. E. K. BACON read a paper on "Anatomy and Physiology of the Visceral Sympathetic and its Bearings on Pelvic, Abdominal and Mental Troubles," April 21, before the Wayne County Medical Society.

Cincinnati.

Dr. DAVID DEBECK, at the last meeting of the medical staff, was elected to the position of ophthalmologist to St. Mary's Hospital. The service here is larger and more varied than that of any other hospital in this vicinity.

Dr. JOHN MILLER, late resident physician to the Good Samaritan Hospital, in company with Dr. Daniel Heyn, will complete his studies abroad, at the hospitals in Freiburg, Berlin and Vienna.

HOSPITAL INTERNES.—The recent examination for internes to the Cincinnati Hospital, resulted in the choosing of four from the Miami and four from the Ohio Colleges; from the Ohio, Drs. John W. McKee, Samuel Iglauer, W. A. Smith, and John S. Morrison; from the Miami, Drs. Beeson, Boggess, Dean and Hines.

THE COMMENCEMENT exercises of the Miami Medical College were held Tuesday afternoon, May 3, at Odd Fellows Hall. The valedictory address was made by Dr. Dan Millikan of Hamilton. Twelve men were graduated. A banquet was tendered to the graduating class and alumni by the faculty, the same evening, at the Burnet House. The regular paper of the evening at the Academy of Medicine was by Dr. James Rowe on "Icterus Neonatorum," and gave an epitome of the known theories of this peculiar disease. Was discussed by Drs. Ashburn, Gillespie and Mitchell. This was followed by a timely and interesting article on "Granular Conjunctivitis," by Dr. Francis Dowling. The prevalence of this disease in the armies of ancient and modern history was touched upon, and the consequences arising therefrom on account of neglect of treatment. The treatment recommended was with jequirity and especially forced expression under anesthesia. Discussion was by Dr. DeBeck. Dr. Ricketts reported a case of a woman from whose vagina he had removed a pessary which had been inserted nineteen years before for retroverted uterus. He had made an attempt to pass a catheter on the woman, which had signally failed. The foreign body was easily found on examination and as easily removed. The woman was also afflicted with peritonitis and a section made. She died within twenty-four hours. The pessary was exhibited. The attendance at the Academy was small, due to the fact that a large number of the regular attendants were at the banquet of the ex internes of the Cincinnati Hospital.

ACADEMY OF MEDICINE.—The paper of the evening, May 9, was read by Dr. Philip Zenner, on "Neurasthenia." Among many causes, the essayist looked upon heredity as one of the most important. Among acquired causes, the worry attending business affairs, the sequelæ of infectious diseases, especially influenza, he regarded as peculiar factors. He thought that grip was especially common as a forerunner of neurasthe-

nia occurring among physicians. Whether the hard work and worry of physicians during an epidemic of grip, or the disease itself was the causal factor, he did not know, but thought both. He did not wish to say much as regards symptomatology, preferring to proceed at once to the more important matter of treatment. He did not pin his faith very strongly to drugs, though approving of tonics to improve general nutrition. He thought that the first desideratum was rest. In mild cases partial rest would be sufficient; lying down for an hour after each meal; getting up a little late in the morning; discontinuing work at an earlier hour than usual. The higher the grade of the disease, the more rest required, so that in the very severe cases the rest treatment of Weir Mitchell was an essential element in the cure. Suggestion is often needed to remove the abnormal ideas with which the patient is possessed. The patient should never be laughed at, as this often does great harm, lessening the patient's confidence in his physician and in the curability of his malady. Homicidal tendencies, which are often confided to the physician, may sometimes be entirely dispelled by stating that there are no such instances on record in his particular disease. Exercise should only be advised in the mild cases and never be pushed to the slightest degree of fatigue. Change of climate, especially mountain trips, change of occupation, sea voyages, etc., are often the only treatment required. Discussion. Dr. Ravogli, who called attention to the prevalence of neurasthenia among those afflicted with a posterior urethritis, either with or without a stricture of large caliber. Whether it is due to the worry of the local disease or from the poisons absorbed from the urethra itself, he was not prepared to say, but thought both agents were at work. The speaker also urged that in syphilis neurasthenia was by no means uncommon, especially among those who had been saturated with drugs. Indeed he considered the super-saturation in many cases as the causal factor. In his experience the neurasthenic condition had often disappeared with a cutting off of the anti-syphilitic remedies and the substitution of a simple tonic. Dr. H. M. Brown reported three cases of what he believed to be neurasthenia, in which all attempted suicide and two were successful. He regarded the disease as allied to insanity. Also discussed by Drs. Langdon, Kiely, Molony, and the essayist. At a recent meeting of the academy, considerable discussion occurred as to the stand taken by the local telephone company. Slot machines have been placed in all drug stores possessing phones, and with the following exceptions all using them are required to deposit a dime in the slot: The druggist is permitted to call up local drug houses, drug stores and physicians; physicians are allowed to call up their offices. Several amusing (to the non-sufferers) and exasperating experiences were related. One physician called up his office and received word that one of his clients, also a phone subscriber, wished to speak to him immediately. He was compelled to deposit his little dime. Another was called to see a serious case and desired immediate consultation with a surgeon. Not wishing to leave his patient, he gave a list of six surgeons to her husband and told him to get the first available. The man called up the six, one after another, but was unable to get any of them. Nevertheless it cost him sixty cents. A committee was appointed to confer with the powers that be to attempt to obtain more privileges for physicians and their clients.

ABOUT two weeks ago a young adult colored male was admitted to the receiving ward of the Cincinnati Hospital with smallpox. The eruption was well out. He gave a clear history, having been until a few days previous at the points in Kentucky where the disease is now prevailing. The diagnosis was confirmed by Dr. Ravogli. Examination of the blood showed clear hyaline elongated vibrating bodies, of the shape of a spirillum or bacillus, over one-half the diameter of a red corpuscle within the substance of the red corpuscles. A considerable number of the red cells contained these bodies. The case was immediately isolated and passed through a typical course to convalescence. No other cases have developed in the city.

AT the annual meeting of the Ohio State Medical Society, May 4-8, at Columbus, the following Cincinnati physicians read papers: "Some Medical Aspects of Capital Punishment," Dr. F. O. Marsh; "Psychic Treatment of Disease," Dr. Philip Zenner; "Removal of the Cecum for Malignant Disease," Dr. J. C. Oliver; "Surgery of the Pneumatic Sinuses of the Skull," Dr. Robert Sattler; "Ectopic Gestation, What Cases to Operate Upon," Dr. J. Ambrose Johnston; "The Clinical Importance of the Position of the Stomach," Dr. H. W. Bettman; "Two Interesting Breast Cases," Dr. Albert Freiberg. Several others were down for papers, but were not present. Dr. J. A. Thompson of this city was re-elected secretary of the society for the ensuing year.

Societies.

The following meetings are noted:

California.—Southern California Medical Society, Santa Barbara, May 4.

Georgia.—Floyd County Medical Society, Rome, May 4.

Illinois.—Chicago Medical Society, May 11; Chicago Pathological Society, May 9; McLean County Medical Society, Bloomington, May 5; Vermilion County Medical Society, Danville, May 10; Warren County Medical Association, Monmouth, May 6.

Indiana.—Tippecanoe County Medical Society, Lafayette, May 2; Vigo County Medical Society, Terra Haute, May 5; White River District Medical Society, Washington, May 10.

Iowa.—Boone Valley Medical Society, Eagle Grove, May 3; Polk County Medical Society, Des Moines, May 3; Wapello County Medical Society, Ottumwa, May 13.

Kansas.—Montgomery County Medical Society, Caney, April 29.

Maine.—Academy of Medicine and Science, Lewiston, May 9.

Maryland.—Baltimore County Medical Association, Baltimore, May 4.

Massachusetts.—Connecticut River Medical Association, Bellows Falls, May 3; Suffolk District Medical Society, Boston, April 30.

Michigan.—Barry and Eaton Medical Society, Nashville, May 5.

Minnesota.—Minnesota Valley Medical Association, Mankato, May 10.

Missouri.—Central District Medical Society, Sedalia, May 5; Jasper County Medical Society, Joplin, May 3; St. Louis Medical Society of Missouri, May 14; Southeast Missouri Medical Association, Cape Girardeau, May 3.

New Jersey.—Camden Medico-Surgical Society, Camden, May 2; District Medical Society of Camden, May 10.

New York.—Albany County Medical Society, Albany, May 10; Cayuga County Medical Society, Auburn, May 12; Erie County Medical Society, Buffalo, May 11; Madison County Medical Society, Oneida, May 10; Medical Society of Newburg Bay, Newburg, May 10; Medical Society of Saratoga Springs, April 29; Onondaga County Medical Society, Syracuse, May 10; Orange County Medical Society, Goshen, May 3; Steuben County Medical Society, Hornellville, May 10; Union Medical Society, Troy, April 28.

Ohio.—Cuyahoga County Medical Society, May 12; Lucas County Medical Society, Toledo, May 6; Miami Valley Medical Society, Loveland, May 3; Ohio State Pediatric Society, Columbus, May 3.

Pennsylvania.—Bucks County Medical Society, Doylestown, May 1; Lycoming County Medical Society, Williamsport, May 3; Perry County Medical Society, Buncannon, May 5; Schuylkill County Medical Society, Pottsville, May 3; Susquehanna Medical Society, May 3; Washington County Medical Society, Washington, May 11; Westmoreland Medical Association, Mt. Pleasant, May 3; York County Medical Society, York City, May 5.

South Carolina.—Association of Colored Physicians, Orangeburg, April 27.

Tennessee.—Marshall County Medical Society, Lewisburg, April 28.

CHANGE OF ADDRESS.

Anderson, J. A., from 348 Winchester Av. to 802 Edwards Av., Chicago.
Black, J. F., from Cleveland, Ohio, to Springfield, Mass.
Burns, E. J., from Galveston to Giddings, Texas.
Colle, J. A., from Chicago, Ill., to Williams Bay, Wis.
Cook, C. D., from 183 Pacific St. to 162 Remsen St., Brooklyn, N. Y.
Carson, C. J., from Chicago to Mortimer, Ill.
Downey, W. S., from 4803 Union Av. to 925 W. 56th St., Chicago.
Doane, P. S., from 1723 Belmont Av. to 855 N. State St., Chicago.
Davis, H. I., from 2962 Wabash Av. to 3120 Indiana Av., Chicago.
Dryden, Mary V., from 489 Ogden Av. to 1926 Wabash Av., Chicago.
De France, C. C., from 328 E. 5th St. to 115 Des Moines St., Des Moines.
Emmons, J. W., from Sparta to Oregon, Wis.
Fehr, H., from Chicago to 304 9th St., Milwaukee, Wis.
Goodhue, W. J., from 893 Ogden Av. to 267 Honore St., Chicago.
Gallen, G. F., from Chicago, Ill., to Calumet, Mich.
Hison, H. M. T., from 756 Jackson Boul. to 718½ Adams St., Chicago.
Hogue, R. R., from Chicago, Ill., to Sparta, Wis.
Hindman, A. O., from Pittsburg, to Crosscreek Village, Pa.
Jordan, A., from Richmond, Va., to Galnes Mill, Va.
Jones, E. A., from Louisville, Ky., to Baltic, S. Dak.
Jones, H. G., from Chicago, Ill., to 2d Reg. O. V. I. Hospital Corps, Columbus, Ohio.
Kirkland, B. F., from Chicago, Ill., to Mt. Auburn, Iowa.
Kohler, A. E., from Chicago, Ill., to Muncie, Ind.
Miller, R. E., from 291 31st to 5808 State St., Chicago.
Martin, Wm., from 324 Blue Island Av. to 122 W. 12th St., Chicago.
McManes, M., from Chicago, Ill., to Celina, Ohio.
Mitchell, G. D., from 1840 N. Clark St. to 7033 Parnell Av., Chicago.
Mathewson, E. H., from Battle Creek, Mich., to Keene, Texas.
Nash, G. W., from 804 Illinois to 712 South Illinois St., Indianapolis.
Nagel, J. S., from 210 Honore to 555 W. 79th St., Chicago.
Nichols, C. L., from Chicago, Ill., to 1223 Wirt St., Omaha, Neb.
Oren, S. A., from Laporte City, Iowa, to Lanark, Ill.

Proctor, C. M., from White Sulphur Springs, Mont., to Shenandoah, Ia.
Quincy, M. A., from Memphis to Ashland, Neb.
Rietz, P. C., from Chicago, Ill., to Manitowoc, Wis.
Reid, W. J., from 244 Alfred to 914 18th St., Detroit, Mich.
Robb, R., from Keokuk to Littleton, Iowa.
Redman, L. H., Alpha to Scipio, Ind.
Rich, F. D., from Terre Haute, Ind., to 380 Erie St., Toledo, Ohio.
Shoemaker, S. A., from Indianapolis to Reiffsburg, Ind.
Smith, H. S., from 592 6th St. to 1184 Vinewood Av., Detroit, Mich.
Tomlinson, J. P., from Atlanta, Ga., to Lake Butler, Fla.
Tunney, J. T., from Chicago, Ill., to Wabasha, Minn.
Williams, E. C., from Chicago, to Bloomington, Ill.
Yaw, S. B., from New York, N. Y., to Avalon, Ga.
Zimmerman, W., from Milwaukee to Menasha, Wis.

THE PUBLIC SERVICE.

Army Changes. Official List of Changes in the Stations and duties of officers serving in the Medical Department, U. S. Army, from May 7 to May 13, 1898.

Acting Asst. Surgeons Llewellyn P. Williamson, Francis Metcalfe and Randolph M. Myers, U. S. A., will proceed from Washington, D. C., to New York City and report in person to Major George H. Torney, Surgeon, in charge of Hospital Ship, for duty.
Acting Asst. Surgeons Edwin W. Patterson and Edgar A. Vander Veer, U. S. A., will proceed from Washington, D. C., to Atlanta, Ga., and report in person for duty, to Major Blair D. Taylor, in charge of the General Hospital, Fort McPherson, Ga.
Acting Asst. Surgeon F. A. E. Disney, U. S. A., will proceed from Washington, D. C., to Ft. Jefferson, Fla., and report to the commanding officer of that post for duty.
Acting Asst. Surgeon Wilfrid Turnbull, U. S. A., will proceed from Washington, D. C., to Key West, Fla., and report in person for duty to the commanding officer, Company E, Battalion of Engineers, at that place.
Acting Asst. Surgeon G. M. De La Torre, U. S. A., is assigned to duty with the 10th Infantry, Tampa, Fla.
Acting Asst. Surgeon, W. P. Lawrence, U. S. A., is assigned to duty with Light Battery B, 1st Artillery, Fort Tampa, Fla.
Acting Asst. Surgeon Edward T. Gibson, U. S. Army, now at Minneapolis, Minn., will proceed without delay to Fort Yates, N. D., and report to the commanding officer of that post for duty.
A contract having been made with Dr. Carroll E. Edson of Denver, Colo., for duty as Acting Asst. Surgeon at Ft. Logan, Colo., he will proceed to that post and report to the commanding officer for duty.
Capt. William C. Borden, Asst. Surgeon, is relieved from duty with the 3d Infantry in camp near Mobile, Ala., and will report in person to Major William R. Hall, Surgeon, for duty at the General Hospital, Key West, Fla.
Acting Asst. Surgeon H. P. Jackson, U. S. A., will proceed from Charleston, S. C., to Key West, Fla., and report in person to Major William R. Hall, Surgeon, in charge of General Hospital, at that place for duty.
Acting Asst. Surgeon Charles K. Cutter, U. S. A., now on duty at Boston, Mass., is assigned to duty as assistant to the attending surgeon and examiner of recruits in that city.
Major Edward T. Comegys, Surgeon, is relieved from duty at Ft. Sill, O. T., and will report in person to Major General John R. Brooke, U. S. A., commanding provisional corps, Camp George H. Thomas, Chickamauga National Park, Georgia, for assignment to duty as acting medical purveyor for the supply of troops stationed at that point.
Acting Asst. Surgeon Frederick S. Dewey, U. S. A., will proceed from Oklahoma City, O. T., to Ft. Sill, O. T., and report in person to the commanding officer at that post for duty.

The Journal of the American Medical Association

VOL. XXX.

CHICAGO, ILLINOIS, MAY 28, 1898.

No. 22.

ADDRESS.

THE PHYSICIAN IN PRACTICE.

Annual address to the graduating class.

BY LEO M. CRAFTS, B.L., M.D.

DEAN AND PROFESSOR OF NERVOUS DISEASES IN THE MEDICAL DEPARTMENT
OF HAMLINE UNIVERSITY (MINNEAPOLIS COLLEGE OF PHYSICIANS
AND SURGEONS).
MINNEAPOLIS, MINN.

Gentlemen of the graduating class:—You stand at the gateway of futurity. What it may hold for you depends upon yourselves and the use you make and have made of your opportunities. In the vista of life there stand out a few bright spots: here and there an isolated eminence rises above the common level. There are events in life that mark epochs for the individual. Such is this occasion for each of you. Tonight, at the same moment, closes and opens a chapter. This is an hour fraught with deepest significance. You have arrived at this moment, so long anticipated, only by years of diligent study, by long hours in the lecture room, the laboratory and the clinic, and by much burning of the midnight oil. Only by unremitting pursuit of a determined purpose and a definite choice, have you reached the cherished goal. Choice determines destiny, upon the underlying purposes of our lives depend our choices.

In the elevation of our ideals must ever rest the character of our achievement. Prompted by what diverse motives and with what ends in view, you entered upon the study of medicine *you* only know. It is trusted that realizing its grave responsibilities, recognizing its unequalled opportunities for helpfulness and appreciating its necessities for self-sacrifice beyond that of any other calling, you have entered upon it solely from the standpoint of unselfish service. For, "the physician's first duty is to his patient; his second only, to himself, and the physician who reverses it is a quack." No other profession demands so much of preparation, and compels so rigorous and extended a course of training as does the study of medicine, and rightly so. That this is true you are fully aware. Your sensations are very much like those of the small boy who has partaken of too much Christmas plum pudding. You feel stuffed to every atom of your being with the fundamentals of the science and art of healing, gathered from every department of the limitless field of medical lore. Every intracranial fossa is crowded. Every convolution and gray cell is teeming with yet unassorted and unassimilated knowledge. Full as you have drunken you have scarcely tasted the swelling stream of learning. All it has been possible to give you has been simply a beginning. The door of knowledge has only been opened. You have been led but a few halting steps on the rugged and endless path along which you must henceforth climb alone. To what pinnacle do you aspire, what impress will you leave upon the

dawning century? Remember that "the demand for something better than that which now exists never ceases." Fields for discovery and research lie fallow before you, and there is a place in the temple of fame for him who will.

"In that fair niche by countless billows laved,
Trace the deep lines by Sydenham engraved,
On yon broad front, that breasts the changing swell,
Mark where the ponderous sledge of Hunter fell;
By that square buttress mark where Louis stands
The stone yet warm from his uplifted hands."

It may not be given to any of you to find a place in that charmed circle of immortals whose work stands as the stepping stones by which medical science has mounted to its present exalted place. The world has never known the names of many of the truest heroes and noblest martyrs who have humbly, in obscure byways of life, followed the daily round of their engrossing duties, unheeding as unheeded by the outer world, "doing what they could do well, without a thought of fame." What powers you may possess no one knows. If you have the capacity for work, for ceaseless and untiring effort, there is nothing to which you may not aspire. Many of the men whose names lend greatest luster to the profession achieved their place in the face of the most untoward circumstance, by sheer force of merit. The same way is open to you.

If in your brief course of training, severe and thorough as it has been, you have learned to love study; if you have acquired a true thirst for knowledge and the search for truth for its own sake, and beyond that for the great uses to which you may devote it in the interest of suffering and afflicted humanity, your instruction has fulfilled its highest mission and your future is assured. It is not the simple knowledge that you have actually gained that is of chief value to you, but the habit of application, the power of selection and analysis, the mental training. Much as you know there is still much for you to learn. Things that can not be taught in any school make up the determining balance for each learner in the school of life; a knowledge of one's self and his limitations, the maturing of judgment and self control, the appreciation of how limited and how circumscribed is all our knowledge, even at its widest and its best. To recognize how little we know is the surest symptom of improvement, for while

"Knowledge is proud that he has learned so much,
Wisdom is humble that he knows no more."

Incompetence is a more fatal fault in medicine than anywhere else. There is no place here for weak hearts or feeble, untrained intellects. All the liberal professions are much overstocked. The number of graduates in medicine annually greatly exceeds the demand. Too many good clerks and mechanics are yearly turned into poor doctors. Hardly one practitioner in forty attains to anything of eminence or success. There is place only for men of the first

ability and the highest training, men who are ready to battle against all odds, capable of ceaseless application and the devotion of a lifetime.

The standard of requirement in medical education has made rapid strides in this country in the recent past. But a few years since, only two brief sessions of five months were required for graduation; while every reputable school at present demands four full years of study. The greatest defect now is the low standard of preliminary training requisite for entrance on medical study. Many men of far too little general education enter all our medical schools, either to be stranded by the way or to be graduated utterly unfit to practice, a menace to the public and a disgrace to the profession. Until this is remedied dangerous men will still be turned loose to practice on unsuspecting victims. And it will not be remedied till institutions of medical learning are placed on a plane above self-seeking motives and the need of students' fees for maintenance. It is a most gratifying indication that every advance in grade made by a medical school has been followed by increased attendance, and always by men of higher attainments. Harvard and Johns Hopkins have taken the highest stand, having recently declared a college degree necessary for entrance. Hasten the day when the Medical Department of Hamline University shall follow this illustrious example. The proportion of college bred men in the various schools of the country varies from 3 to 43 per cent. To the credit of this class be it said that one-half of your number hold previous degrees.

In the minds of many, a diploma is a passport to social position and professional success. But you will find it no touchstone of entrance to the inner courts of preferment. You must stand or fall on your own merit. You are going out to face not an inviting but a frowning world. The universe has not been waiting your coming. You must make your own place in it. Do not expect success too soon. There is long and tedious waiting before you, and it is well, although in it there are both dangers and advantages. Many, becoming discouraged and disheartened by the long delay, lose ambition, give up the unequal struggle and drift into the first opening that offers a livelihood. But if you are made of the right stuff and stick where you start, with worthy determination, employing the waiting time in earnest study, and unassuming diligent effort, the reward will surely come, but only when you have demonstrated your intention not to succumb. One young physician, starving in Liverpool, had not a single patient in three years, and another, locating on a leading London street, received one call in seven years. Do not expect recognition from rival fellow practitioners until your rising reputation compels it. You will not find all brotherly love and harmony in the profession. You will meet opposition where you least expect it. You will receive merciless criticism and slurs where you might anticipate favor. The discreditable bickerings that disgrace the profession are born of petty jealousies and are utterly beneath its dignity. Always be ready to give full credit to merit, even in your rival. You will never suffer by it. If you can not speak well of him, say nothing. You can not build yourself up by pulling another down, and you only damage your own when you assail another's reputation. Yet do not hope to avoid creating enmities, but so far as possible, and consistent with self respect, avoid creating needless opposition. Many a young

physician prejudices and handicaps his whole future by injudicious and obnoxious aggressiveness, born of immoderate egotism. Quiet attention to your own affairs will build surely and broadly for ultimate success. In all your conduct, both toward your fellow practitioners and the public, may you be imbued with a standard of medical ethics irreproachable from the most elevated professional standpoint, resisting with uncompromising opposition the growing tendency to its disregard which threatens to degrade the noblest of callings to a commercial basis and a huckstering trade, and so to remove the sharp line of demarcation between the reputable physician and the unprincipled charlatan.

Your ultimate success will depend upon many other things as well as upon your training and ability. Personality counts for very much in winning your way, a pleasing presence is a most fortunate possession. There are doctors whose daily visit to the sick room is a better tonic than any medicine, and it is said of an eminent Boston physician that his smile was worth \$5000 a year to him. While we can not remodel the endowments with which nature has favored us, we still can do much in the cultivation of pleasing manners. It is as easy to be affable as to be curt. It costs no more to be a gentleman than a boor. Your habits of life will be of the utmost importance both to yourselves and to your patients, and most important of all is the habit of temperance. In no other walk in life can a man afford so little to indulge in dissipation, and yet every community has its wrecks of brilliant and able practitioners who have swamped all in the glass. A mind befogged, reeling and dizzy with alcohol is in no fit condition to think clearly, to act with prompt decision and certainty in those great emergencies which come to every physician, when a human life is in the balance and to err is fatal. "Intemperance in a physician," says Dr. Holmes, "partakes of the guilt of homicide." Self control is an absolute essential. The greater the emergency, the calmer and clearer must be your thought; ready to act on the moment, yet always with full deliberation. Never be in a hurry, it unsettles your nervous equilibrium and vitiates your judgment. Remember the story of the young doctor who received his first call while in the midst of a shave. Scrubbing the lather from his half shaven face, he started on his mission, burst into the sick-room in breathless haste with the anxious inquiry, "How long have you been sick?" "Twenty years," calmly replied the invalid—ample time to have completed his toilet.

Always respond to calls promptly and without unnecessary delay. Moments seem hours to anxious friends, and evident neglect is not easily forgotten. Be prompt in all your appointments. An hour's wait in anxious anticipation, beyond the time of your expected visit reacts unfavorably both for yourself and your patient. Be considerate and kindly in all your surroundings. Be sympathetic, genuinely, truly, deeply sympathetic. A physician without sympathy is a misnomer, and is never the truest success. You must be versatile, resourceful, self-reliant, "ready to show a new front as often as the situation shows a new peril." Attention to the insignificant details will prove of more importance in your success and your results than the master strokes of medication. The little things that concern the ease and comfort of the patient outweigh your more pretentious treatment. Be very careful in your selection of remedies,

study each case to its last symptom. Keep all its possible contingencies constantly in mind, that you may be ready to meet promptly any change, and not be taken unawares by a flank movement of the enemy. There is no occasion for dealing in mysterious and meaningless terms. A frank, clear statement is due the patient or his friends. Yet beware how you take away hope. Your opinions must be given with caution and with tact. If you can not command the entire confidence of the patient withdraw from the case at once, for you can accomplish little without it. Always be open to conviction, but do not hope to avoid mistakes for they are inevitable. You can never conscientiously keep a patient for a moment when you know he can get better help elsewhere and when you do, you become a pirate and a brigand; the robber on the highway is less guilty. In all your advice and counsel, especially surgical, put yourself in the subject's place and recommend for him only what you would have for yourself, your sister or your mother. There can be nothing but condemnation for that too common spirit that operates only for the zeal of operating or the added pecuniary returns, a stain from which surgery, both special and general, is not altogether free. You are to perform, or to recommend, surgical or other procedure, only when the welfare of the patient demands it.

The conduct of the medical life is filled with advantages and opportunities of growth shared by no vocation to the same degree. It will develop your judgment, broaden your sympathies, make you more charitable in your estimate of motives; and while it shows you at times, human nature at its worst and its lowest, and many things will cross your path that will tend to shake all your faith in humanity, you will, on the other hand be let into the secret chamber of heroic suffering, and have glimpses of nobility and grandeur of character that will flood and tinge all life with its beauty and before which we bow in reverent homage. It will make you shrewd and discerning. No one can look through the hearts of men and read their lives in their faces as can the experienced physician. No one knows human nature so well. In no other walk in life are there such privileges for helpfulness, to speak a word of comfort in time of trouble and loss, to pour balm into aching hearts, to lead up to aspiration when all is despair. "There are times when the physician has power for good or evil exceeding that of any other man, when the mind of the patient is filled with forebodings, when the past is dark and the future without hope, he is more ready to listen and be influenced than at any other time." The secrets of the inmost life, sacredly guarded from the world, are revealed and laid freely before you. Those confidences must be held as absolutely inviolable. You are to enter your patient's house only to do him good and in all your conduct to avoid the very appearance of evil. It is a matter of wonder that comparatively so few men of high ideals of life and true Christian spirit are attracted to the study of medicine, and the catalogue requirement of high moral character in the candidate for a degree is worth no more than the paper it is printed on. The medical profession should be open to, and entered upon, only by men of the highest character, the most gifted nature and the noblest soul.

To attain any measure of success you must have the confidence of the community. To gain and hold this you must merit it. Govern your conduct by dignity, honor and becoming modesty. Your waiting

time, through which all must pass, may be spent to better advantage in reading and study than in exchanging stories with the loafers at the corner grocery. You must be constantly investigating and advancing. The universal tendency is to stagnate and rust. Set no limit to your ambition. No possibility is beyond you. Never rest content with any vantage gained. Press steadily, untiringly on.

"Still achieving, still pursuing,
Learn to labor and to wait."

The life of the physician is peculiarly trying and his duties most exacting. He has no moment that he can call his own, night or day. Everything must give place to the call of duty. The strain, the exposure and fatigue are extreme. Endurance is taxed to the utmost. Utterly forgetful of self, he is beautifully and ruggedly drawn by MacLaren in the character of Weelum MacLure of Drumtochty who "did his best for every man, woman and child, year in, year out, in the snow and in the heat, in the dark and in the light, without rest and without holiday." Often the greatest sacrifice is a thankless task and goes without reward. For although there is nothing a man will not do to regain lost health, there is no obligation he is so slow to discharge as his physician's just due. The returns of medical practice are disproportionately small. The true physician, generous, charitable, benevolent, gives little thought to his fees and has educated the public to do the same. His chief concern is for the welfare of his patient, and he is too forgetful of himself. The financially successful practitioner, in a large way, is usually only a self-calculating business man, concerned first for his fees, and secondly, if at all, for his patient. He is rarely a sympathetic, great-hearted, broad and genuine physician.

Your responsibilities and obligations do not end with your purely medical work. You come in closest touch with the great heart of the world. You will know its trials, its shortcomings and its virtues most intimately. The family physician occupies a position entirely unique and shared by no one else. You may be the greatest possible power in society for moral conservation. You are in a position to act and speak with influence as no one else can. You can warn, and guard and encourage with the voice of counsel and authority. So, helping and helpful, devoting yourselves to the good of humanity, family adviser and friend, living beyond your time in lives elevated and made better by your walk among them, shall the evening of life be serene, though hastened by exposure and stress and devotion to its duties, risks and dangers, receive the same loving homage that was the part of that gnarled old hero of Glen Urnach.

Canon Liddon has thus beautifully, and we trust truly eulogized medicine: "The profession of medicine is from its nature, I had almost dared to say from the necessity of the case, a teacher of benevolence. Often we have witnessed the transformation, one of the most beautiful and striking to be seen in life, by which the medical student becomes the medical practitioner. We have known a medical student reckless, selfish, or worse and presently behold him a medical practitioner, more unselfish and devoted than any other member of society. What is this something, akin to ministerial ordination, which has brought such an inspiration of tenderness and sympathy. The answer apparently is, he approaches human suffering from a different point of view. As a student he looked upon it as something to be observed, discussed, analyzed, anyhow lectured

upon, anyhow examined in. As a practitioner he is absorbed by the idea that it is something to be relieved. This new point of view, so profoundly Christian, will take possession of a man's whole moral nature and give it a totally new direction. Thus the medical practitioner is at once the master and teacher of the purest benevolence. This is true of those great lights of the profession whose names are household words. But it is even more true of many practitioners of whom the public takes no note, and pre-eminently so of the obscure country doctor, upon whom the sun of publicity rarely or never sheds its ray. His life is passed in the homes of the very poor, and in acts of the kindest and most self-sacrificing service. For him the loss of rest and the loss of health is too often nothing less than the law of his work, and as he pursues his career, so glorious yet so humble, his left hand rarely knows what his right hand doeth. And yet such men as these maintain the state of the world. They pour oil or wine, as can or do few or none others, into the gaping wounds of our social system."

And now we are come to our parting. You will go out to find and make your own place and to carve your own destiny. It has been my pleasant and grateful privilege to address to you, on behalf of the faculty, this brief word of counsel, caution and advice. In their name I now welcome you to the ranks of the medical profession. In their name I extend to you the right hand of fellowship. In their name I bid you Godspeed in your chosen calling; not unmindful of the solemn responsibility we assume in thus standing sponsor for your knowledge, your skill and your conduct. You are the children of an honored university. You have a double obligation to discharge, that which you owe to yourselves and that which is due your *alma mater*. For upon you must rest the mantle of her reputation. See that you keep it pure, unsullied and unspotted. May you go out into your life work only to augment the luster of her fame as you build your own.

"The distant murmur which you hear will soon grow louder, and you will find yourselves swept into the whirlwind of the world's tumultuous conflict. Go forward in hope and serene courage. Disease is calling you from his bed of anguish. Death is looking for you to smooth his pillow. Posterity is expecting you, impatient to be laid in his cradle."

You have crossed in safety the shoals of the harbor bar of examination, though at times your keel may have grated ominously on the bottom, and you float at last in the still harbor of anticipation. You must now weigh anchor and stand out on the swelling main of life, spreading sail to the quickening breeze. Headwinds met and buffeting storms outridden, may the favoring winds of Providence make sure and complete the voyage that shall at last bring anchor securely in the harbor that is beyond the vale.

"We live in deeds, not years; in thoughts, not breaths;
In feelings, not in figures on a dial.
We should count time by heart-throbs when they beat
For God, for man, for duty. He most lives
Who thinks most, feels the noblest, acts the best."

Rectal Injections of Arsenic are highly recommended by Professor Renaut, in tuberculosis, diabetes and Basedow's disease for their tonic and soothing effect. They can be continued for weeks or months with occasional interruptions without disturbance of any kind. He orders 5 c.c. of a solution of arsenious acid containing one third of a centigram to each 5 c.c. three times a day. *Nouv. Remèdes*, April 24.

EXPERIMENTAL WORK ON THE PENETRABILITY OF VAPORIZED MEDICAMENTS INTO THE AIR PASSAGES.

Read at the meeting of the Mississippi Valley Medical Association in Louisville, Ky., Oct. 8, 1897

BY HOMER M. THOMAS, A.M., M.D.

FELLOW CHICAGO ACADEMY MEDICINE; CONSULTING LARYNGOLOGIST HOME FOR CRIPPLED CHILDREN; CONSULTING PHYSICIAN NOSE, EAR AND THROAT DISEASES, MARY THOMPSON HOSPITAL. CHICAGO, ILL.

Hippocrates was the first to devise a simple apparatus for the purpose of inhalation. In the seventeenth century Bennett recommended inhalation for consumption. Infusions of aromatic herbs (*halitas*) or even balsamic vapors (*suffitus*) were used. The discovery of oxygen revived new trials in this line. It was finally abandoned as air contained but little oxygen, and it was thought the atmosphere would have a more beneficial effect. Some hydrogen, nitrogen and even carbonic acid were used by Beddoes. Well remembered is the recommendation to physicians of that time, and even to the present, to inhale the air of stables containing cattle. About 1820 chlorin and iodine were tried with favorable effect; also turpentine vapors in chronic bronchitis. Murriate of ammonia vapors, the steam of escaping sulphur springs, the salty air in salt mines and the smoke of datura stramonium furnish further examples. A decided step forward was made by the improvement of the technique in vapor productions, especially the possibility to break up the fluids mechanically in finest globules after having dissolved the medicaments. In 1858 Sales-Girons introduced the first transportable apparatus for the vaporization of medicaments, to the Academy of Science in Paris. The new method soon found enthusiastic adherents as well as bitter foes. The chief query was, how deep does the fluid enter the lungs? By experiments on animals and on men, by chemic examination of sputa, by the laryngoscope, by inhalation of stained fluids it was proven with absolute certainty by the friends of this method, that it was possible for medicamentous fluids to enter the finest bronchi and alveoli. The penetration into the alveoli of the corpuscular elements, coal dust, etc., by inhalation was further proven. Peroxid of iron was found as a pigment in the lungs of miners, by Zenker.

The various anatomic examinations of diseases introduced from inhalations due to industrial pursuits, as anthracosis and calcicosis (Zenker), and researches of Leon, Hirt, Steubner, G. Merkel, E. Wagner and Arnold leave no doubt of the penetrability of lung tissue by fluids or corpuscles, by inhalation. The possibility for a local therapy of the lungs seemed evident and all available medicaments were tried, but critical observations and experiments soon limited the possibility of this method. Dr. Adolph Schmid (Reichenhalt) says, inhalation therapy can not be regarded as a curative means: it has to play the more modest rôle as a supporting means to the other methods of treatment. It is likely to influence diseases of the respiratory passages by modifying various symptoms. Within these limits it must be considered as a method to be employed with good reason and difficult to do without. J. Schreiber, in 1888, by painstaking experiments gave a fair explanation of the influence inhalation had on diseases of the lungs. He con-

tends that finely pulverized particles may enter into diseased lungs through the bronchi and even into the alveoli; that in order to produce the application to lungs in this way we must have a combination of pressure and aspiration effect. The pressure effect at the entrance of the respiratory passages must be felt equally at all portions of the lungs. In practice it has been assumed that aspiration is equal in both healthy and diseased portions of the lung; it is not remembered that there must be a difference. If the lungs have lost elasticity so that new air no longer enters, it follows that substances mixed with air will not enter. The diseased processes which so lessen the elasticity are not sufficiently considered. It has been found that in healthy animals exposed to air loaded with coal dust, the larger and smaller bronchi were reached in fifteen minutes; that in animals with diseases of the lungs, as bronchitis and miliary tuberculosis, substances mixed with atmospheric air enter in even greater quantities than in healthy animals. But the distribution of substances is very uneven: for while coal dust can be seen in clumps in healthy lungs nothing whatever appears in diseased foci. This general law applies not only for infiltrations and scars (that is, where there can be no air), but also for processes accompanied by ulcerated foci and cavities.

In an abscess wall coal dust was not demonstrable, yet it was equally distributed in the healthy lung. In a number of rabbits two drops of oil of turpentine was, by a parenchymatous injection, introduced into the right lung: an inflammatory process was established, attended with a fibrinous exudate; the rabbits were all exposed to coal-dust atmosphere with the result that in the injected lung no coal dust entered, while in the healthy lung it did. There was doubtless an anatomic process which made it impossible to respire coal dust in the one lung, but with easy facility in the other. It was found, however, when the injections were made into both lungs that the coal dust entered both. The result of these experiments demonstrates the fallacy of the assumption that the aspiration strength of the lung is identical for air and for bodies mixed with air. They show also that corpuscular bodies in the air do enter into diseased lungs and even under certain circumstances more abundantly than in healthy lungs. This phenomenon may be explained from the fact that the aspiration strength of the diseased foci is decreased; in healthy foci increased, hence less resistance in healthy than diseased lung. If the anatomic process is only unilateral then inhalation is negative; if bilateral aspiration strength is even, and bodies mixed with air enter.

Do vapors act locally? The pathologic processes in which vapors are used are associated with alterations in the respiratory mechanism and vital capacity of the lungs. Portions of the parenchyma of a lung, bordering on a cavity; where there is an abscess or gangrene is also altered, therefore not only the main focus but also the surrounding parenchyma, for a greater or less distance, takes less or no part; and so the respiratory filling of diseased regions of the lungs, may be incomplete in both degree and duration. The act of inspiration begins later and ends quicker. In those portions of the lungs where there is a slight hindrance to ventilation of diseased foci, as mucus or swelling, it would be sufficient to prevent all ventilation of the diseased foci: and these conditions would have greater effect upon the vaporized medicaments than the air itself. Hoffmann says this form

of treatment should be used in diffused catarrhs.

One difficulty which has appeared to lie in the way of the thorough application of drugs to affected air passages has been in the unsatisfactory action and imperfect construction of the various atomizing inhalers furnished the profession. These instruments have either been too delicate in construction to permit the use of sufficient pressure to make possible a deep penetration of the vaporized medicament into the air passages, or became so easily clogged up as to create great annoyance in their use.

The instrument I present is the result of my effort to overcome the objections mentioned. It consists of a heavy glass bottle, ten inches in length and twelve inches in circumference at its widest portion narrowing at the top to a circumference of three and one-half inches. The bottle part is of very heavy glass and is tested to withstand a pressure of one hundred pounds to the square inch. The atomized vapor is produced through a tube of German silver heavily nickel-plated, which is nine inches in length. Three inches from

Figure 1.

the lower end are two tubes, the ends of which approximate to within one-eighth of an inch of each other. The opening of the inner tube is one-third of that of the outer tube, which is one-half inch in circumference. When in use the motive power, which is compressed air, varying in pressure from five to fifteen pounds to the square inch, enters the main tube and two-thirds of it is ejected at the mouth of the inner tube, the remaining one-third passing down into the medicinal menstruum, from which it assists in forcing a solid column of the medicament to the mouth of the outer tube. The whole mass is then projected in an atomized form against the inner side of the bottle near the top, whence it falls in rivulets to the bottom of the bottle, the residue escaping from the top through an outlet opening, in the form of a fine smoke-like vapor. A screw cap, within which is a screw-thread three-quarters of an inch in length, securely anchors the top to the bottle. I have found this instrument to be strong, durable, easily cleaned, perfectly antiseptic and meeting the requirements of this special form of medication.

I now report my series of experiments:

Experiment 1. A kitten was placed in a plain box, twenty-one inches long, eleven wide and twelve high, with dovetail seams. A one half inch hole two inches from the bottom was made for the entrance of vapor and a similar hole at the top for vapor exit. The vapor used consisted of 5 per cent. pure iodine

in a two-ounce solution of lavolin. Compressed air, nine pounds to the square inch, produced the vapor in the inhaler. Vapor was introduced continuously for twenty minutes. The kitten was then removed and immediately killed by an injection of sixty minims of a 3 per cent. solution of prussic acid, per rectum. The respiratory tract was dissected out and the starch test for the presence of iodine was applied to the air passages. Iodine was found present in the mucus from the mouth, on the tongue, in the pharynx and larynx; a typical iodine reaction was obtained the entire length of the trachea to just below the bifurcation to the bronchial tubes; a slight iodine reaction was found in the upper part of the larger bronchi.

Experiment 2.—Animal used, a kitten. A 10 per cent. solution of the trichloride of iron in lavolin was vaporized in the box for twenty minutes. The kitten was then killed by a 3 per cent. solution of prussic acid, introduced per rectum. A solution of ammonia sulphocyanide was then used to determine the presence of iron salts. Result: A marked reaction in the mouth, tongue, pharynx and larynx. No test visible on the epiglottis, trachea, bronchi or air cells.

Experiment 3.—Animal used, a ten-pound dog. A 7.5 per cent. solution of pure iodine in blandine was introduced into the box for twenty minutes. During this time the dog was much excited and made strenuous efforts to escape, as a consequence his respiratory efforts were greatly accelerated. At the end of twenty minutes the dog was killed with a 3 per cent. solution of prussic acid, per rectum and the starch solution used upon the air passages to determine the existence of iodine. Result: There was a hyper-secretion of mucus, which tested with starch showed the existence of iodine on the tongue, pharynx, larynx, trachea, larger bronchial tubes down to the medium sized. A microscopic examination of the mucus was found to contain iodine. There was also found iodine extending as far down as the openings of the smaller bronchial tubes. This experiment positively demonstrated that the starch test solution was colored by iodine to the mouths of the smaller bronchial tubes. There was no evidence of iodine in the pulmonary alveoli.

In the succeeding experiments a box of the following dimensions was used: Twenty-seven and three-fourths inches long, eighteen and three-fourths high and twelve wide, inside measurement. Capacity of box equals 6243 $\frac{3}{4}$ cubic inches. A one-fourth inch opening was made in the middle of the top of the box for the entrance of vapor, and a half inch opening two inches from the bottom for vapor exit.

Experiment 4.—Animal used, a guinea pig; medicaments used, a 20 per cent. solution of iodine in lavolin; time, one hour. It is necessary to use the saturated solution because the iodine combines with the oil. A thirty-drop solution of prussic acid, per rectum, was used to kill the pig. A teased specimen from the lungs was made and iodine found to the openings of the minute bronchial tubes. The objection to the teasing method is that no positive air vesicle can be gotten into the microscopic field. For although epithelial cells covered with iodine may be found, yet it is possible they may have come from the epithelium of minute bronchioles. This experiment positively demonstrated the existence of iodine in the second subdivision of the bronchial tubes.

Experiment 5.—Animal used, guinea pig; time, two hours; mixture used, a 10 per cent. solution silver nitrate in glycerin and water. Pig was killed with prussic acid, per rectum. Result: Grossly the lungs had a silver metallic lustre. Microscopic sections revealed metallic pigmentations. Paraffin sections showed pigment very beautifully surrounding air vesicles.

Experiment 6.—Animal used, a guinea pig, taken from city hall, where air is contaminated with sewer gas and carbon; killed by prussic acid, per rectum, without exposure to any vapor. My purpose was to make a microscopic test of the appearance of the lungs of a guinea pig which had and which had not been subjected to a vaporized medicament. Result: I was surprised to observe that the appearance in the lungs of the vaporized and unvaporized pigs were almost identically the same. Alveolar pigmentation was present in both lungs and appeared much the same.

Query: Do not all guinea pigs have their alveoli pigmented? Being unable to satisfactorily clear up this vital point in vapor experimentation I decided to secure a guinea pig from a source where the air was pure. Accordingly Mr. E. R. Gibbs of Norwalk, Ohio, was communicated with and killed a pig from

his farm with chloroform, immediately dissected out the lungs and expressed them to me. A microscopic examination of the air vesicles showed that they were entirely free from pigment. Hence it was concluded that a guinea pig's pulmonary alveoli are, when respiring pure air, free from pigmentations.

Experiment 7.—Animal used, a guinea pig, secured from a point well supplied with pure air, medicaments used lavolin, holding iodine in suspension. The per cent. of iodine was not constant nor great, time of inhalation two and one-half hours, death produced by prussic acid per rectum. The lungs were removed while the heart was beating; were thrown into plain water; placed on a freezing microtome and frozen before the heart stopped beating. Sections were removed from the blade of the freezing microtome to a 2 per cent. formalin, others to 1 per cent. osmic acid. The formalin specimens after five minutes were mounted in water and examined. Result: The smaller bronchial tubes and air vesicles were filled with large, flat epithelial cells; many of these were loaded with fat; some of the fat was in small granules, some in globules about one-third as large as a cell. The other sections remained in osmic acid twenty-four hours, when they were washed with water and stained with saffranin and mounted in Canada balsam. The osmic acid specimens showed the fat stained black; the fat is clearly within the cell.

I attribute the comparative failure, in some of the earlier experiments, to demonstrate vaporized medicaments in the alveoli to be due largely to the irritating substances that were used, namely, iodine, iron salts and nitrate of silver. The animals after a few minutes' exposure to the vapor had a hypersecretion of mucus which appeared in the nostrils and the mouth; when this had formed, the air entering the respiratory passages was obliged to bubble through a large amount of mucus. No doubt the material in the vaporized air was largely taken out in passing through the fluid. The success of the experiments seem to depend largely upon the persistency of the vapor; also in avoiding too irritating a vapor. The vapor as produced by my inhaler, is certainly very persistent. When the animal is taken out of the box closed some fifteen or twenty minutes and then again opened it will be found to be still filled with vapor.

Experiment 8.—Subject male, age 40, Pole, place Cook County Hospital, disease secondary anemia and septicemia following suppurating tonsillitis, vapor used lavolin slightly flavored with oil of gaultheria, time of inhalation twenty minutes. The respiratory movements were very complete with unusually deep forced inspiration and almost normal expiration. All of the accessory respiratory muscles were brought into play during the period of inhalation. Previous to the vaporization the lungs of the patient were examined and found normal.

Soon after death a postmortem was made. A small section was cut from the lower lobe of the left lung and placed upon a freezing microtome. When ready, sections were made and placed under a high objective. They revealed oil globules in the alveoli. Another section of the lung from the lower left lobe was put in osmic acid the following morning and allowed to remain seventy-two hours. Sections were then made by a freezing microtome. They show well stained oil globules within the alveoli. This I believe to be the first time a demonstration of a vaporized medicament penetrating into the pulmonary alveoli of a human lung has been made.

Reasoning upon the demonstration of oil globules in the pulmonary alveoli of the healthy lung, is it possible for any globules to reach localized diseased areas? I think it generally admitted that vaporized medicaments have an established therapeutic value in diffused catarrhs of the respiratory passages as far down as the larger bronchial tubes. The present extent to which vapors are used in the treatment of diseases of respiratory passages is sufficient evidence that they

are of considerable local benefit in the treatment of affections of these passages down to the smaller bronchial tubes. I have repeatedly seen good results in

FIG. 2.—The fat is shown black. This is due to staining with osmic acid. 1. Large cells containing the oil. 2. Alveolar walls so cut as to show roof or floor composed of epithelial plates.

treatment of localized inflammations of the bronchial tract by inhalation as far as the second division of the bronchi. I have obtained results in that way that I

FIG. 3.—1. Masses of fat in cells. Much of this is in spherical globules. 2. Epithelial cells of alveolar wall. 3. Sections of alveolar wall so made as to give appearance of more than one layer of lining cells.

have repeatedly failed to secure with internal medication. It is surprising how the respiratory ability can be increased by a little instruction and effort.

✻ In treating cavities of the lungs that are accessible to the air current there is certainly a field for this

kind of medication. There is no reason why a phthisical cavity accessible to the air current can not be antisepticized in this way. There is no reason why an alveolar cavity should not be disinfected with vapor as readily as a bronchiectatic cavity. If this can be done considerable relief can be afforded patients. Where there have been pathologic changes in the lung tissues it appears to be another question. It would seem as if we strike a limitation which is an interference with natural respiratory processes on which the success of inhalation depends. In such a condition it would seem as if the bulk of the inhalant would be diverted to those portions of the lung which are compensating for the diseased areas. In inspiratory tuberculosis, up to the time we have necrosis of lung tissues, there is a portion of the lung which we desire to reach by inhalation, apparently effectually blocked by catarrhal products both within and without the alveoli. In tuberculosis due to infection from the lymph or blood cells we have a focus upon which it is deposited extra-alveolar, and which is usually surrounded by more or less connective tissue growth, which theoretically would seem to offer a serious barrier to the passage of any vaporized medicament through the alveolus, even supposing, through osmotic action or any other process, such a passage was possible. Theoretically, it would seem that there exists mechanical limitations to the effect of any such treatment in tubercular diseases. However, it is time to stop theorizing and see what can be demonstrated. It is probably true that inspired solid particles do not reach beyond the area of ciliated epithelium, but in the form of vapor here produced there is an intimate mixture of the molecules which largely favors passage beyond this area. Diffusion is a molecular rather than a gross current. The residual air in lungs is changed every seven inspirations. Hence in healthy lungs there appears no pathologic objection to the penetrability of vaporized medicaments into the pulmonary alveoli.

In animal experimentations the co-operation is wholly unintelligent and involuntary, while the use of vaporized medicaments among most patients is attended with a considerable degree of intelligence and voluntary assistance. The field alone of treating catarrhs of the lung, localized bronchitis, accessible cavities and the good that will accrue from the increased expansion of the lung induced by such treatment, is of itself ample ground to encourage us in persisting in this line of medication.

An interesting point to ascertain would be what per cent. of the vaporized medicaments used are retained within the pulmonary alveoli. Pascal demonstrated that by ordinary methods of inhalation about one-fifth of the vapor is retained. Hence in the past this line of treatment has not been of very much practical benefit on account of the small amount of vapor which has been contained within the bronchial tubes and perhaps within the alveoli. I believe this apparatus is capable of causing the retention of a large proportion of the vaporized medicament. By placing patients under the influence for a considerable length of time, we certainly do a great deal of good in the local treatment of catarrhal disorders of the respiratory passages.

703 Marshall Field Building.

Time for Administering Medicines. Alkalins, before meals; acids, between meals; irritating toxic substances, immediately after meals. Phosphates and malt extracts should be taken with the meals and sublimite, tannin and alcohol only when the stomach is completely at rest. *Tribuna Méd.*, February 28.

EXPERT MEDICAL WITNESSES; WHAT IS
THE CAUSE OF THE SEEMING DISRE-
PUTE IN WHICH THEIR TESTIMONY
IS HELD IN CERTAIN RECENT
CASES IN THE COURTS?

OBSERVATIONS FROM THE STANDPOINT OF THE
COUNTRY DOCTOR.

BY J. HOWELL WAY, M.D.

EXAMINER IN ANATOMY, NORTH CAROLINA STATE BOARD OF
MEDICAL EXAMINERS.
WAYNESVILLE, N. C.

The criticisms by the daily press of the country on the expert testimony in recent noted cases in the courts where medical gentlemen eminent in our profession, occupying positions of great responsibility to the profession as teachers and consultants, and to the public in that from the position accorded them by the profession they become men whose works weigh much with the laity, have evoked considerable attention from the writing part of the profession. These articles I have read with the greatest interest, feeling that out of the discussion would be evolved valuable suggestions.

For quite a number of years past the idea of an "expert commission" to be created by law, and to which all questions of a medical nature arising in the courts would be referred for examination and solution, has been periodically sprung on a suffering profession. Recently it is noted that the same suggestion has been going the rounds of the medical press and is seemingly the more favored solution of this *questio verata*. For a republican form of government it is more than probable that there are already too many men in "commission" to do this or that particular thing which the people could do for themselves in their own time and their own way, and perhaps equally well. Yet this idea of a commission, advisory to the court, seems to be the favored solution, the main remedy offered on various hands for the abatement of what is claimed as the source of great danger to the future character and influence of the profession. It is difficult to see how the proposed scheme could, if it were practicable to carry it into effect, prevent the troubles of which the doctors complain in regard to the operations of the present system. Take for illustration, the Carlyle Harris case in New York a few years since, or the more recent Luetgert case in Chicago; in each we have some of the most prominent medical gentlemen in their respective cities, going on the witness stand and flatly contradicting each other about scientific questions.

Now, if as is generally understood science knows no variation, if it consists of certain fixed laws, these gentlemen must have known what part of their testimony was scientific facts and what part was opinion, conjecture or possibility. Would medical men be more inclined to agree with one another before a commission than in the glare of the public's gaze in the open courts? Doubtful. But it is assumed that the idea of a commission would involve the submission of medical points involved in medico-legal questions arising in the courts to men of special and profound knowledge only. Just how this would make the matter better, except for the favored few who constituted the commission, can not at present be shown. The very prominent experts are those who are constantly getting into the newspapers with the odium of the courthouse "wranglings of the doctors" and resultant criti-

cisms attached to them, and through them to the profession for which they are assumed to stand. It is my opinion that in the smaller cities of the country and the rural districts where there are fewer or no "professors" of medicine, that the matter of expert testimony is developed in the courts with far less friction between the opposing sides and with a corresponding degree of credit to the doctors. In the past twelve years it has occasionally fallen to the lot of the writer to appear in the courts in the capacity of an expert medical witness, and he here records his court experiences as among the pleasures of his professional life. But certain rules have always been scrupulously followed. First, the witness has never received a fee from either side prior to his appearance in the courtroom. His cases have been carefully studied beforehand, and after conferring with the other medical men who were to appear in the case, and adjusting any great differences which might on first view have seemed to have existed between them, he has gone on the witness stand and told in the simplest language possible what he knew of the case, strictly avoiding all professional technicalities. When my opinion is asked as to a question which is unsettled in the minds of the profession I invariably, after a word of explanation, confess my ignorance. And right here, I believe, lies the trouble with so many of the modern metropolitan medical experts, they try to know too much, there is too vast an amount of professorial, professional or personal dignity at stake for the expert to say candidly "I don't know," and the clever attorneys fully appreciating this fact play on the doctor's weakness, and when the proper time arrives the expert's testimony and his foibles are shrewdly dissected before the jury. I have no criticisms to make of the attorneys. They can legitimately prey on any man who opens the way. My observation is, that as a rule medical men are themselves responsible for the ridicule their evidence is occasionally subjected to in the court room. On every hand the fact is appreciated that marked advances have been made along all the lines of human activity in the past two or three decades, and in none has there been a greater degree of activity displayed or greater results produced than in the field of scientific medicine. Far be it from the intention of the writer to cast one iota of obloquy upon the good work of our honored profession in detracting from the splendid record of progress in recent years, but the practical fact remains that every new idea has not, as some of our brothers would have us believe, been an improvement on the old or an advance to the front. While the general tendency of our professional life in scientific work has been distinctly and emphatically forward and upward, yet to borrow the figure of another in our evolution, "some of the branches of the tree of progress grow upward and to the light, some grow downward soon finding their terminal buds, some wither and die, yet it takes all to make the tree." So as honest men we must admit that while substantial advance is made every day, we are even now absolutely in the dark as regards the correct solution of countless scientific problems in medicine.

A distinguished savant makes an experiment today which he hopes will lead to something; the next day the details of the experiment are heralded the earth over as a most wonderful demonstration of established facts. The day following the same scientist, or hundreds of co-workers in the fields of science, repeats the experiment and finds that a certain element of error

not calculated for in the original experiment, renders null and void the assumed conclusions of the first day. The general public are not informed of this, however. Later they find out the facts and then their respect for scientific expounders and their science is proportionately lessened. Witness tuberculin! Call to mind the excited throngs, both of students and afflicted, who flocked to Berlin during the few months following the announcement of Koch's discovery. To bring it nearer home, look at the history of vaginal injections during and after labor. Only a few years since it was gravely announced by those high in authority in the medical world, that no woman should be permitted to bring forth offspring without her genitals being rubbed, scrubbed, scraped and injected with strong solutions of toxic drugs a certain number of times (the details of the process almost suggested Hahnemann's directions in his "Organon" for preparing a "potency"), then a pad of the famed spices of the Orient was to be placed at the vaginal entrance to frighten timorous microbes away. Such was the dictum that with "professorial" sanction went out over the country; notwithstanding this, there were intellectual "giants in those days" who dared to reason a little for themselves and questioning, said, is not this a violent perversion of nature's methods? And while perhaps the many of the profession were for the time swayed by the injection idea (largely because it was "new" and "the latest") there was a very large portion who rejected it as an illogical treatment. On my desk lies an ably written article recently published, from the pen of an acknowledged authority on obstetric science, inveighing against the practice of using vaginal injections in labor and criticising the monthly nurse for her disposition to use the douche whether so advised by the attending physician or not. Yet this article does not give a hint as to where the aforementioned nurse was indoctrinated with the supreme necessity of vaginal injections in labor.

The idea of the writer is to direct attention to what he believes to be one of the chief causes of the threatened disrepute into which it is gravely asserted expert medical testimony is in danger of falling, and incidentally to note that the general, every-day practitioner of medicine can not afford to endorse such ideas as tend to produce the belief that relief is to be found in putting "in commission" certain gentlemen who will attend to the elucidation of medico-legal questions for the profession and the courts. The severest wrangling over medical cases in the courts comes when gentlemen of the class, from which it is proposed that the commission be created, appear in the courts on opposing sides.

To get at the cause of the trouble is our first duty, then to remove it if possible. One of the dangers which an expert, and the more reputation he has to sustain the greater the danger is likely to encounter, is that of knowing too much. If medical men were as ready to admit in the court-room their real ignorance of many things, as they are in the privacy of the consultation room there would be far less wrangling of the experts, with the result that much more respect would be entertained for their evidence. Doctors are oftentimes, rather than make a frank confession of ignorance, tempted to build up on one known fact in medicine, coupled with half a dozen conjectures a theory which they may believe, but do not and can not know. This theory is then elaborated and given to the court as an exposition of the teachings of medical science.

This is all wrong, but we do not need to invoke the aid of legislation to set such things right, but rather the exercise of common sense. It is a family affair and should be settled by those most interested. In every case where medical witnesses are summoned, if these medical experts will get together and calmly and critically review the evidence of each man, throwing out what is only conjecture or rests on insufficient scientific foundation, leaving to be given out what is generally accepted by the profession as known facts; then later, when on the witness stand, with an eye more to truthness to professional honor than to being the plaintiff's or defendant's "doctor," tell what he knows and resist the allurements of keen-witted counsel to extract information which he does not know, that man will retire from the stand conscious of having maintained his self-respect. He will also merit and receive the respect of the court. A proper appreciation of this plan ought to make it possible to put it into operation with the masses of the profession who have regard for their professional honor. Apply the method herein suggested to the practice of medical jurisprudence in the courts and it is not likely that self-respecting medical men will, after carefully studying a case together, go into the courtroom and exhibit the spectacle presented in the recent Luetgert case, where given a small fragment of the upper extremity of a femur, one gentleman swore positively it was in his opinion the femur of a human female, the other with equal positivity asserted it to be the femur of a hog. On the day following the astute attorney produced in court bones known to have been derived from a chimpanzee, which bones were identified by the experts as human. Imagine the humiliating position of these gentlemen; amusing to the spectators and disgusting to every plain, common-sense doctor who followed the testimony. Both medical men should have testified that the bit of bone was the upper end of the thigh-bone of a mammalian, and mentioned some of the more common animals from which the bone might have come. They should have positively stated that with the very short fragment exhibited, it was impossible to say it was or was not a human bone (after days of wrangling this is really what their conjoint testimony amounted to). This course would have saved their credit and that of the profession in general, which is always affected more or less by the actions of its members. It is true this would have been indefinite, but (as the sequel proved) it would have been the truth, and when told in a simple dignified professional way would have enabled the doctors to have retired from the stand with more honor than attached to the experts whose perhaps too ample *ego* led them to know too much. These gentlemen were acknowledged expert comparative anatomists. The blunder as to the chimpanzee bones, the positive divergence of opinion as to the source of the piece of femur exhibited to them, presuming as we do that the experts told what they believed to be the truth, proves conclusively that comparative anatomy is not as yet sufficiently an exact science to enable one, from only a small part of a bone (unless it should be a part possessing some very special or pronounced processes or foramina, etc., rendering its character unmistakable) to positively identify it as coming from the body of a certain animal. Now to candidly admit this fact need bring no discredit to our profession or to the individual doctor so testifying. We are not expected to know everything in the courthouse, whatever may be the

demands made on us in the sick room. A clear recognition of this fact of the part of the professional man, coupled with a sincere regard for stating, when on the witness stand, only what are known to be established facts, and a disposition not to allow the erudite attorneys to lead him to become a partisan, will I think, contribute very greatly to advance the esteem in which expert medical testimony is held by the courts and the general public. These remarks are intended to apply more particularly to the general masses of the profession, the practical men who help nature save and prolong the lives of their fellow-creatures. Can not these gentlemen, so clamorous for special legislation, see that the very fact of their more or less valuable services being had by either side in any case, carries with it the death-warrant of the call for professional experts in the courts of justice. The American people are of a very practical type, and a few more exhibitions of medical experts *à la* Luetgert style will make the masses feel that these experts are all frauds. But long after this *genus* shall have for remembrance only a "trace of mould" in the sociologic layers of the past, there will still be more or less frequent calls from the courts of the land for some plain, practical observations on medical questions coming before them, from the plain every-day common-sense doctors who have opinions only about things of which they know (and are not embarrassed at not knowing all things), and not based on what might, could, would, should, or did not happen.

SOME SUGGESTIONS CONCERNING THE EXAMINATION AND COMMITMENT OF THE INSANE.

Read before the Medical and Surgical Association of
Maryland, Feb. 25, 1898.

BY GEORGE J. PRESTON, M.D.

Professor of Nervous Diseases, College of Physicians and Surgeons,
Baltimore; Consulting Neurologist to Bay View Asylum, City
Hospital, Hebrew Hospital, Church Home, etc.
BALTIMORE, MD.

The commitment of an individual to an asylum is an act of serious import, and often of far-reaching consequences, and it should be attended with more care and thought than is often awarded it. There are two considerations always to be borne in mind, the first of great importance, namely, the consequences to the patient, and second, a much less important point, but nevertheless one that must be considered, the consequences to the committing physician.

In regard to the first point, there is often rather too much haste in sending patients to an asylum. I have not infrequently been called to sign a commitment for a patient in whom the mental condition was simply one of depression from over-work or over-worry, which was relieved by a trip away from home. More often still have I been asked to commit a patient with hysteria. Another class that I am frequently asked to send to asylum is the class that may be called in a general way "eccentrics," persons who can not be classed as paranoiacs, but who do very illogical and foolish things. Finally, there are neurasthenics, hypochondriacs, mild demented from organic brain disease, and persons who congenitally are, while not exactly feeble-minded, below par mentally. To be added to the number already mentioned are cases of distinct mental disease, concerning whom the question arises whether they are better off at home or in an asylum.

Thus it is evident that the duty of the physician is not to find out whether there is sufficient mental disturbance to warrant commitment to an asylum, but to decide the very difficult question whether the patient should or should not be sent away from home.

It is not intended, in this brief paper, to discuss the question of home versus asylum treatment, but merely to point out the method of conducting the examination. It is, in general, best to approach the patient in the capacity of a physician and not resort, as is often done, to some mild deception. The patient need not be told that an examination is being made to determine the question of sanity, but it is always easy to explain the physician's visit on the ground that the patient's friends or relatives wished something done to relieve the "nervousness." A little tact will always succeed in the mild cases, and in the violent there is no need of deception. One often sees patients thrown into a most suspicious attitude toward physicians after having been deceived.

A general physical examination should always be made of the organs of circulation, respiration, digestion, etc. Then the state of the nervous system should be inquired into, the state of the reflexes, the pupil, sensation, the existence or not of muscular atrophy, the presence or absence of paralysis and the like. It is extremely difficult to formulate, in words, the mental condition. After a careful examination one should be able to say in regard to the general intelligence whether it is good or not. The patient's social status, education and environment must be taken into account. Various current topics should be touched upon, and the condition of the memory, both for early and recent events, noted. If the patient is irrational the nature of the conversation should be observed. The general demeanor of the patient should be noticed, as to whether there is present exaltation, excitement, complacency, anger, fear, depression, suspicion, dread and the like. I am in the habit, for purposes of convenience, of classifying the mental state according to the various phases of alcoholic intoxication. For example, a patient will exhibit the mental state of an individual in the early stages, the furious stage, the emotional stage, etc., of alcoholic intoxication. It is to be regretted that we have no arbitrary standard by which to represent the mental condition. This examination has a twofold object: First, it is important to know the patient's general condition, so as to be able to judge how far disease of organs, other than the brain, may be responsible for the supposed mental symptoms. Then this routine examination offers an excuse for obtaining the patient's history and for asking any questions designed to test the mental condition or to elicit evidence as to the existence of hallucinations or delusions.

Some patients are eager to deluge any listener with their delusions, while others are very unwilling to speak of them. It is useful to obtain as clear a history as possible from relatives or friends regarding the patient's conduct or false beliefs. At the same time it is to be borne in mind that the relatives are apt to be very biased witnesses, sometimes refusing to admit evidence of marked mental disease or attempting to explain away certain incontestable symptoms, at other times laying undue stress upon hysteric or other functional manifestations. The history thus obtained indicates the presence or absence of delusions.

A great deal of tact is necessary in bringing out delusions, for insane individuals are often dimly aware

of the fact that certain of their beliefs are regarded with suspicion by their friends and associates. When questioned bluntly concerning certain delusions which are supposed to exist, it is not uncommon for the patient to refuse to talk upon the subject. Again, I have known patients who, having been warned by legal advisers not to speak upon the topics about which they had delusions, were able for a considerable time to obey this injunction. It is nearly always possible, however, by patient and wary questioning, to get the insane individual headed toward his delusions if any exist. This is much easier to accomplish if one knows beforehand what the nature of the delusion is. The examination of a suspected case of insanity should never be hurried. In many cases one may recognize the existence of insanity at a glance, but in others many and repeated examinations are necessary either to bring out the delusions or to demonstrate the patient's sanity.

One is often asked on the witness stand if the time alleged to have been devoted to the examination of a suspected case of insanity was sufficient. Such a question must be answered in a very general way. If certain incontestable evidences of unsound mind have been adduced then the examination, however brief, was sufficient to establish the question of insanity. If, on the other hand, the examination was negative, it is necessary to show that the patient was examined carefully upon all the subjects on which he was suspected of having entertained delusions. A single examination, with negative results, should rarely ever be relied upon. When a question has been raised, as to the mental condition of an individual, sanity is often far more difficult to establish than insanity. As was remarked before, patients are often unwilling to speak freely of their delusions. There is at present under my care a lady who was under observation in a private room in a hospital for more than a month before she gave any conclusive evidence of the existence of delusions. She simply seemed greatly depressed but would never give any reason for her depression. Although I had seen her nearly every day for a month I could never bring out any semblance of a delusion until one day she told me that all the people who passed the hospital shook their heads at her and showed great joy at the fact that she had been deprived of her liberty.

One should be cautious in accepting statements made by the patient as evidence of the existence of an insane delusion unless the facts of the case are well known. This is particularly true in regard to alleged ill treatment by relatives and questions involving property. Sometimes so-called delusions are simply exaggerated statements of existing conditions. Not infrequently I have been obliged to agree with the supposed lunatic in regard to the treatment received at the hands of relatives. This brief reference to some of the salient points to be noted in the examination of a case of supposed mental disease will suffice to show the care with which such examinations should be conducted. It is only by the exercise of this caution that mistakes can be avoided. By mistakes is not meant simply the commitment of sane persons to an asylum: this is sometimes, though in my opinion very rarely done, but the commitment of persons to an asylum who could have been treated as well at home.

Unfortunately, in this country there remains a great deal of the old feeling regarding the insane and asy-

lums. A person who has once been committed to an asylum bears an ineffaceable stigma. Then too, in the mind of the laity such undue significance attaches to the hereditary influence of an isolated case of insanity that the fact that a member of a family has at some time been committed to an asylum constitutes almost a blot upon the escutcheon. These considerations attest the grave responsibility resting upon the physician in committing a patient to an asylum and demand a more thorough examination of the patient and his environment than is sometimes employed.

The consequences to the physician in wrongly committing patients to asylums rarely rise to the point of criminality. Such instances could be mentioned but, to the credit of the profession be it said, they are extremely rare. On the other hand, it happens very often that physicians are culpable in not making a more thorough examination of supposed cases of insanity. Most of these mistakes are known only by the asylum superintendent, although not infrequently they are recognized by the patient's friends afterward. The place where this careless and superficial work is frequently shown up is in the court room. Anyone who has had much court experience in cases of insanity must have seen a great many instances where lawyers have shown most conclusively, that the examination of the case of supposed insanity has been made in the most careless manner. Often the statements of relatives, more or less known to the physician, are taken to prove the existence of mental disease. Then it is most common to find that the physician has made no general examination of the patient and is unable to state whether or not any evidences of organic disease exist.

Great discredit has of late been cast upon expert medical testimony in regard to insanity. While in some instances the so-called expert is criminally corrupt or simply incompetent, in many and perhaps the greater number of cases, his examination has been entirely inadequate. It would be well if our medical journals would take more interest in the expert testimony given in the courts and analyze the more important cases. In this manner the profession would be placed in a position to pass judgment upon the medical testimony and the medical expert.

THE PETERSON HOSPITAL AT THE CRAIG COLONY FOR EPILEPTICS.

BY WILLIAM P. SPRATLING, M.D.

MEDICAL SUPERINTENDENT CRAIG COLONY.
SONYEA, N. Y.

The Peterson Hospital at the "Craig Colony for Epileptics" was designed for the care and treatment of acute medical and surgical cases only, and its capacity is from twenty to twenty-four beds. Located as it is in a colony of this kind, it is more than a hospital only, as will be pointed out.

The style of architecture is not ornate, simplicity and solidity being the chief features aimed at. It is two stories high, with an ample basement that is light, well underdrained, and in which are located the heating and hot water supplying appliances for the building, besides containing ample storage room for miscellaneous supplies. It is constructed of a superior quality of red pressed brick, with blue stone foundation walls to the water table, and trimmings of the same stone throughout. It measures from front to rear 66 feet; from side to side 120 feet; and its lines

are so run that sunlight enters all of the rooms at some hour of the day.

The main entrance faces north and on passing into the building by this door the main hallway, 18 by 26 feet, with a projecting hallway half as large as this and running from it to the rear, is entered. The main hallway will serve the additional purpose of a public reception room.

To the right is a spacious well lighted apartment, to be occupied by the assistant medical staff as an office. Immediately in the rear of this office, and including the intervening hallway, are the living quarters for the resident medical officer.

To the left of the main entrance is the physical examination room, and opening off this a large dark room fitted with all facilities for ophthalmic work and for photographic microscopy. The physical examination room will serve the same purposes afforded by the out-door departments of a metropolitan public hospital. Examinations of all kinds may be made here and all minor injuries receive prompt attention. Adjoining this room is a small apartment in which out-door patients may be isolated and cared for, should they have a seizure while in the building.

Plan of first story.

At the end of the corridor on the left is the drug room, and communicating with this, by means of a raised window, is the waiting room for persons who may come for drug supplies. All the medicine for the entire colony will be dispensed from the drug room. After a tour of inspection over the colony, the physicians will return to the drug room and enter in the prescription book all medicine and druggist's supplies to be used in their respective departments, so that this room will become the central supply station for a population that may reach 1500 or 1800. Adjoining the waiting room is the druggist's sleeping apartment, easy of access to duty or call, day and night. The kitchen is immediately in the rear and connected with the dining room above by a dumb waiter.

The second floor is given up to patients' use, and the problem to be met was to effectually separate the two sexes in a building of this size, and without sacrifice of space.

Ascending the main stairway, a landing is made in a hallway above, twelve feet wide. Opening off from the right of this is the male department, and from the left the female, both entrances being protected by locked doors. At the end of the hallway is the operating room, a well lighted, antiseptically constructed and conveniently arranged room in all respects. It is

equally accessible from the male and female wards. The male and female departments, as will be noted by glancing at the second floor plan, are exact counterparts.

Lying to the north of the hallway leading to the main ward are two wards, 9 by 19 feet, in which one or two beds may be placed, as desired. A well lighted clothes room adjoins the operating room on either side. The main wards are 19 by 20 feet, are perfectly lighted and have effective ventilation. The toilet fixtures and bath are placed in separate rooms, permitting the free use of the bath at all times.

The convalescent rooms are cheerful, abundantly lighted, provided with open fires, and are in easy proximity to the dining room beyond. The doors leading from the convalescent rooms, on either side, to the dining room, will be kept locked, thus providing two sets of locked doors between the sexes. Safety is further assured by the fact that all patients in this building will be confined to bed except during convalescence, after which they will go out into the colony at large.

The operating room is fitted with the most approved and modern operating furniture, and is provided with an abundance of hot and cold spring water that is as pure as can be supplied by nature.

A summary of the purposes it is intended to serve

Plan of second story.

is: 1, For the treatment of acute medical and surgical cases, requiring hospital facilities; 2, as an accident or out-door station for the relief of dispensary cases; 3, as a central hospital and medical supply station for a community with an ultimate public population of from 1500 to 1800.

Dr. Frederick Peterson of New York City, who first agitated the subject of public care for epileptics in America, was honored by the Board of Managers of the Colony when this hospital was given his name.

SPECIAL SANITARY INSTRUCTIONS FOR THE GUIDANCE OF TROOPS SERV- ING IN TROPICAL COUNTRIES.

BY R. S. WOODSON, M.D.
CAPT. MEDICAL DEPT. U. S. ARMY.

Having served in the extreme south during my entire service as a medical officer, viz.: Atlanta, Ga.; Pensacola, Fla.; Laredo, Texas; New Orleans, La.; Savannah, Ga.; and Tampa, Fla., and having made a special study of tropical disease, including yellow fever, it is incumbent upon the writer to publish the following special report of the existing conditions

and the sanitary precautions to be taken in tropical climates for the instruction of troops to be sent therein.

The existing conditions of international complications lead us to believe that the Island of Cuba is our objective point and while I have never been a resident of the island, yet I have taken advantage of the opportunities offered to obtain all information possible from a number of prominent physicians, refugees from Havana.

The adverse sanitary conditions peculiar to Cuba are: 1, numerous infected foci of yellow fever; 2, numerous areas of infection from plasmodia malariae; 3, the plague of insects; 4, the intense solar heat; 5, the intense humidity with great precipitation of dew; 6, smallpox in larger cities; 7, impure water; 8, the danger of sleeping on the ground.

1. Yellow fever is most certainly the greatest danger that confronts us. The mortality of this affection among troops from northern climates possessing absolutely no immunity will be exceedingly great should the disease gain access to their midst. Yellow fever being a disease which attacks essentially the liver and kidneys, will prove particularly fatal to those whose habits of life have reduced the vital resistance of these organs. Especially is this axiom applicable to soldiers with cirrhotic livers and kidneys from alcoholic excesses, and those with lithemia from over-indulgence in highly nitrogenous foods. The term lithemia is intended to define that condition of men ordinarily spoken of as "full habit."

So firmly convinced am I of the predisposing influences of alcoholic indulgences toward this disease that I would strike all such beverages from the dietary of the soldier, and even from the supplies of the medical department. In this connection I wish it distinctly understood that I am not discussing this question from a moral standpoint, and to those who insist that habitual drunkards require their accustomed stimulant I would reply that such men should be left behind, or if carried should be sent up daily a hypodermic injection of strychnin or digitalin.

The latter condition, lithemia, brings us to the subject of foods. I would insist, in this connection, that our soldiers are overfed with nitrogenous food-stuffs, hence the plethoric condition that is often mistaken for health. Many of the men of this command are closely bordering upon obesity, and such men will prove an easy mark for the ravages of a tropical climate. It is probable, however, that in this campaign we shall "live upon sixpence a day and earn it," thus surmounting this difficulty.

I am not an extremist when I insist that the army of occupation should be held in strict quarantine during the whole of its campaign in Cuba, except when military necessities render its observance impossible, and further that the requirement of such quarantine should be most rigidly enforced when approaching a known focus of infection.

The Cuban physicians insist that fruit should not be eaten, especially the mango, they being a fruitful source of yellow fever. They are mistaken, however, in this, and the fruit is free from such infection unless it has passed through an infected focus after gathering. It is recommended, however, that fruit that has been gathered and kept for ripening in infected foci as well as fruit that is unripe or that has begun to decay, be strictly avoided, but the arbitrary dictum that all fruit be avoided is unwarranted.

The writer does not believe that yellow fever is solely a water- or a food-borne disease, but that the infection is carried by small bits of fabric, technically termed fomites, emanating from the person and environments of those sick with the disease, and that the disease gains access to the human system by inhalation.

The principal foci of infection are the cities and towns of Havana and Matanzas provinces, the cities Sagua la Grande, Cienfuegos and Placetas, in Santa Clara, and the city Puerto Principe, in the province of same name.

The provinces Pinar del Rio, Santiago de Cuba, and the Island of Pines are free from infection and comparatively healthy. The trochas which have been inhabited by the Spanish army as well as all military hospitals and old camp sites should be strictly avoided, especially the Jucaro-Moron trocha, extending across the western portion of Puerto Principe. The entire seacoast of the provinces Havana, Matanzas, Santa Clara and Puerto Principe should be avoided as much as possible, the hilly interior being comparatively healthy. The line of safety from sea of course depending upon the topography of the country, but I am informed that it can be conservatively stated at ten or twelve miles upon the average.

Should the disease yellow fever unfortunately attack us, instant isolation of the sick and detention of the suspects in camps of detention and decimation of the command instituted. I use the term decimation in its technical sense. A nice question is involved as to what would be the unit of infection, whether the company, regiment, brigade, division or corps. From my observation I should designate the regiment as the unit and therefore should insist that the infected regiment be immediately isolated from the rest of the command, and as an added precaution all communications between brigades and divisions should be suspended and army corps should be separated until all danger of a further spread of the disease shall cease and only those members of the medical and hospital corps who possess an immunity against the disease should be allowed access to those afflicted. The necessity for rigid camp sanitation I shall not discuss, as among large bodies of men it is required under all circumstances.

2. I have been informed that malarial fevers are rife in many localities in Cuba, but especially that portion of Matanzas and Santa Clara bordering upon the Rio Gonzalo. All low-lying districts with the concomitants of bad drainage, decaying vegetation, intense heat and great humidity should be considered as malarial localities. Although we have never discovered the habitat of the plasmodium malariae external to the human body, we yet believe it to have a telluric origin under the above-mentioned favorable conditions. While it is preferable to avoid such localities the exigencies of military operations will frequently necessitate more or less lengthy sojourns therein.

The writer is firmly convinced that malarial fever is both a water- and an air-borne disease. We can exclude the former by boiling all drinking water, which precaution is earnestly advocated. The latter method of infection is more difficult of control. Then again the mosquito is considered by many scientists, and especially by the Cubans, as the vehicle of infection. They also believe that these insects are the carriers of yellow fever infection. While these theo-

ries may be *sub judice*, yet they must be considered.

Then there are certain conditions of a soldier's life which, though not provocative of disease, nevertheless lower his vital resistance and render him an easy mark. I allude to sleeping on the ground, lack of personal cleanliness, exhaustion consequent upon excessive clothing, weight of personal equipment and exposure to intense heat. It may be justly claimed that a soldier's life necessitates these evils, and the writer gracefully retires whenever the military necessities of a campaign, however insanitary, become imperative, but there are a few of these evils that might be corrected without a corresponding detriment to military efficiency.

3. I have been assured that the mosquito will prove very troublesome. I would recommend that each soldier be issued a triangular piece of mosquito netting to fit over the fronts of their shelter tents. Such a net would occupy small compass and be of little weight.

4. The question of tropical heat combined with intense humidity and lack of acclimation will prove of serious moment to our troops, most of whom are from northern climates and unaccustomed to intense heat. Several cases of sun stroke have occurred among the troops since their arrival at this point. The evil effects of the intense heat can be avoided by shunning exposure to the mid-day sun, abstemious habits as regards food and alcohol, reducing the weight of the soldiers clothing and equipments, and personal cleanliness.

The writer prefers a brown union duck, composed of a mixture of cotton and linen, to be worn with the present leggings and campaign hat, as affording a cool, comfortable and serviceable uniform. I would recommend light weight socks, linen drawers and a light, short armed undershirt, composed of material known to the trade as balbriggan, to be worn under the blue shirt now issued. The present shoe is heavy, shapeless and devoid of all elasticity.

The most important point to be considered in this connection is the knapsack, which from its weight and constrictions of its straps will prove a great hardship in a tropical country. I see, also, that the overcoat has been brought along. I would most earnestly recommend that all knapsacks and overcoats be left behind, and that ponchos be issued in place of the latter. In place of the knapsack the blanket roll is strongly urged, consisting of half shelter tent, blanket, poncho, tent poles, change of underclothing, two pairs of socks, two towels and necessary toilet articles. I would recommend that no extra shoes be carried, and that all other clothing not mentioned be left behind.

5. In regard to the great humidity and dew precipitation, the shelter tent and blanket is probably the only protection that can be offered from a military standpoint.

6. I have been informed that smallpox exists in all the larger cities. The entire command should be immunized against this disease by vaccination.

7. In regard to drinking water, I would strongly recommend that all water for that purpose be previously boiled and subsequently protected. The small suction filter tube used by the Cubans, is not recommended for the reason that it would soon become contaminated and prove a source of infection to sterile water.

8. The Cubans are particularly emphatic as regards

the use of the hammock to prevent contact with the ground. I have given this question a great deal of thought, and while hammocks would unquestionably be of great benefit to the troops, they are not recommended for the following reasons: 1. it would be necessary to carry large heavy upright posts and guy-ropes upon which to swing the hammocks, and the writer is opposed to any addition to the personal equipment of the soldier in hot climates; 2, the hammock could not be swung in the shelter tent, and as the rainy season will have about commenced upon our arrival, this would prove an insurmountable objection. As a substitute I would recommend that each man be issued a poncho to be used upon the floor of the shelter tent, two placed together being sufficient to cover the entire area. This, with a blanket placed over it, will prove as efficient a guard against the dampness and gaseous emanations of the soil as is possible from a military standpoint. Further, the poncho would be extremely useful during the rainy season for the purpose for which it was originally intended.

Many fevers of fatigue and cases of insolation will develop on the march unless every effort is made toward the conservation of the soldier's energy. His personal equipment and weight of clothing should be reduced to a minimum, always considering the requirements of military necessities.

Great attention should be paid to personal cleanliness, because the skin is the great organ for the elimination of heat through the agency of the sweat glands. Such elimination should be encouraged on the march, but care should be taken in the hours of rest against sudden chillings of the surface with consequent determinations to internal viscera. The writer would caution against the excessive drinking of water while on the march, for the reason that while water is enormously beneficial to the system, such drinking during periods of great activity increases largely the volume of blood and limits the powers of a soldier's endurance.

The writer has avoided all points of military hygiene not particularly applicable to tropical climates. All other questions relating to the health of the troops may be left to the superior wisdom and experience of older members of the medical corps.

PROBABLE INFLUENCE OF THE MODERN SMALL ARM PROJECTILE ON MILI- TARY SURGERY.

Read at the Meeting of the Physicians' Club, May 2, 1898.

BY G. FRANK LYDSTON, M.D.

PROFESSOR OF GENITO-URINARY SURGERY AND VENEREAL DISEASES, COL-
LEGE OF PHYSICIANS AND SURGEONS, CHICAGO; SURGEON-IN-CHIEF
WEST SIDE FREE DISPENSARY; SURGEON SECOND REGIMENT
ILLINOIS NATIONAL GUARD,
CHICAGO, ILL.

The modern small arm is destined to be the chief factor in modifying military surgical practice. It is as yet untried upon a sufficiently large scale in actual warfare to determine its practical merits. Certain things, however, have been fairly well established, and multitudinous and varied views have been expressed as to its utility. As the small arm was designed as a superior instrument for the infliction of physical injury, its merits and demerits are perhaps of more interest to military surgery than to any other branch of the service.

The first point for consideration is the question of

the relative danger experienced by non-combatants of the present day, and by the surgeon more particularly, as compared with the past. Until the invention of the modern rapid-fire, extremely long range rifle, it was comparatively easy for the hospital department to put itself in a position which was not only safe, but sufficiently near the firing line to be of the best possible service to the wounded. How much this has changed is likely to be demonstrated in the near future; that it has been changed is unquestionably true.

The modern gun throws its projectile so far that even though the combatants should be actuated by a desire to avoid injuring non-combatants, it is almost impossible to do so, from the fact that if the hospital department be sufficiently near to render prompt aid to the injured, it must be many yards within the maximum deadly range of the guns. If you will consider the comparative ranges of the Springfield rifle and a modern high power arm such as the Lee-Mitford, the rifling of which has been adopted in most of the modern small arms, the point will be at once made plain. Some of the modern rifles, of which the Lee-Mitford is an example, are sighted up to 3500 yards; its minimum point blank range is 300 yards. It is not necessary to alter the sights for any range within 1000 yards. The Springfield rifle, with which most of our volunteer troops will fight the Spaniards, is sighted up to 1000 yards. Its point blank range is 200 yards. From 200 to 1000 yards the sights must be adjusted at the various ranges, which adjustment is the cause of much poor shooting on the part of the soldiers. As I have noticed very frequently in skirmish firing at the rifle butts, many men begin firing at the range of 600 or 700 yards, adjust the sights for that distance, and in the excitement of running and firing forget to adjust the sights properly. The consequence is, that at Springfield, Ill., a farmer who resides behind a high hill surmounting the rifle butts, raises more lead upon his farm during the month of July each year than he does cabbages, and is busily occupied in getting out injunctions against us.

The muzzle velocity of the new weapon, when charged with cordite instead of the compressed powder used in the British army, is nearly 2300 feet per second as against 1600 with black powder. The average deviation in the 45 caliber Springfield ball at 1000 yards is nearly 22 inches, which is almost twice as great as the deviation of the modern small-calibered bullet.

There is very little difference in the modern small arms adopted by different countries. The Lebel rifle used in the French army, the Krag-Jorgenson and Lee used in the United States, the Austrian Maennlicher, the Lee-Mitford used by the British and the Mauser rifle with which the Spaniards are armed differ very little in caliber, and their range is essentially the same.

Proportion of wounded.—In a recent article by Captain William E. Dougherty of the regular army, the following statement appears: "When the potential forces that are now available for warfare, are directed on the battlefield of the future with intelligence and skill the devastation that will be wrought upon the area covered by the conflict and its environment will surpass anything of the kind known in former wars. Conditions and necessities now unknown and inconceivable will press upon the victor and the vanquished alike. The number of wounded will ex-

ceed enormously that of any war heretofore, and the non-combatant auxiliaries, hitherto safe in any shelter behind the close formations, will be compelled to contribute their quota to the mortality and casualty list or abandon their sphere of action."

There will undoubtedly be, as Captain Dougherty says, an increase in the number of wounded, incidental to the immensely increased range of the modern projectile. This should be discounted, however, because of several factors which, so far as I have seen, army officers have failed to take into consideration. First, while the carrying power of the small arm and the penetrating power of the projectile have greatly increased, the keenness of vision of the soldier and his average potential skill in marksmanship has not increased in like proportion. The chances of striking the object aimed at lessen very rapidly with an increase of distance, and it is my opinion that injuries inflicted at much over a thousand yards will be largely a matter of haphazard, and incidental to the carrying power of the weapon from which the projectile is fired alone, rather than to accuracy of aim.

Another point is that it is much easier for the parties fired at to conceal and protect themselves against the enemy's fire at such long ranges; and with the modern magazine gun, close ranges, excepting in great emergencies, are likely to be avoided until the exact value of the magazine gun has been established. Apropos of the magazine gun as bearing upon wounds, it has been suggested that the average soldier will waste more lead than he is worth in using the magazine gun, because of the excitement incidental to action. There is much of truth in this.

I am speaking solely of small arms and not of the small calibered machine gun. When once the desired range and line has been established for that, accuracy of aim is likely to be maintained. Then, too, the machine gun is not effective at long ranges, and is chiefly used in case of assault, where masses of troops are rapidly advancing within the line of fire.

It is safe to assume that the volunteer troops, at least, will be in no wise superior to trained militia. I have already called attention to the amount of waste of ammunition incidental to target practice, where the men are not exposed to danger, unless they happen to shoot each other by accident. I have also noted during battle exercises dozens of men firing their pieces without taking aim. If in battle exercises, or on the rifle range, men are so excited as to throw ammunition away, what must their conduct be when the soldier is enjoying the sensation of being fired at as well as firing? In a general way, very rapid firing from the modern small arm is likely to be very inaccurate; the only thing that is likely to redeem the aim of the soldier is the close approach of a large body of men, and the opportunity of wholly or partially concealing himself behind some sort of breastwork.

Character of wounds. As bearing upon the effectiveness of modern small arms, and particularly of magazine guns, the following is pertinent: It has been claimed that the bayonet and saber, as implements of war, have had their day. According to modern theorists infatuated with the view that the modern small arm is irresistible, bayonet, saber and sword wounds are things of the past. The bayonet is henceforth to be used in digging up trenches and as a cooking utensil, the sword and saber as badges of office. The fallacy of this is well shown by the fact that considerable bodies of Spaniards have been routed, and large

numbers of them killed, in hand to hand conflict with the insurgents, the Spaniards being armed with the best of modern small arms, and the insurgents relying mainly upon their two-foot knives, or machetes. The conditions prevailing in such combats have provided plenty of sword and bayonet wounds. Even the machine gun has not obviated the possibility of such wounds, as shown in one of the recent campaigns against African savages by the British. If I remember correctly, in one engagement one or more Maxim guns narrowly escaped capture by the savages.

The nature of gunshot wounds has greatly changed. That there will be more immediate fatalities upon the field of action, has been universally conceded. The proportion of dead as compared with the wounded will necessarily be greater than heretofore. Whether this is consistent with the alleged superiority of the modern small-calibered projectile is open to argument. A disabled man is not only practically dead, as far as his own usefulness is concerned, but he is worth a couple of dead men to the enemy, because of the expense, labor and embarrassment necessitated by his care.

The Springfield rifle, caliber 45, despite its inferior carrying and penetrative powers, inflicts a wound, even though a vital point be not struck, which, as a rule, immediately suggests to the soldier the advisability of getting out of action. The smashing, stunning, tearing effect of the ball is such that unless the wound be very trivial indeed there are few individuals who are not put *hors de combat* at once. It is perfectly possible, on the other hand, for a soldier to be shot with a small-calibered projectile through and through the body, or to receive a wound which completely traverses a limb, without being compelled to cease firing. Pluck counts for comparatively little when one receives a ball from a Springfield rifle. It may count for a great deal in case of wounds from small-calibered projectiles. The truth of this proposition was amply shown in a battle between the English and the Matabeles. A savage received five severe perforating wounds, and, if I am not in error, did not fall until the troops and savages became engaged in a hand to hand conflict.

The wound from the modern projectile, granting that a vital part is not struck, will, other things being equal, heal very rapidly. The usefulness of the soldier as a fighting unit will be very speedily restored. He will not require as much care, nor will his care be as expensive as if he were wounded with the old pattern of ball. This is very advantageous to the wounded man, but a decided disadvantage to the enemy. The deduction is obvious.

The reasons for the rapid convalescence of the wounded are: 1, the small caliber of the projectile; 2, the cleanness of the wound; 3, its punctured rather than lacerated quality; 4, the infrequency and small size of foreign bodies carried into the wound; 5, the probability of foreign bodies being carried entirely through the wound by the ball; 6, the through and through penetration of the ball itself; 7, the lessened liability to sepsis incidental to the small size of the projectile, its smoothness of surface, and the relatively small quantity of foreign material carried into the wound; 8, the infrequent and comparatively slight importance of bone and joint injuries incidental to the small size and rapid flight of the ball; 9, the relative infrequency of injuries of the large nerves and blood vessels, incidental to the small caliber of the projectile.

I do not wish to be understood as underrating the explosive property of the modern projectile. By the term "explosive," as used in this connection, I refer to the sudden expansion of the tissues incidental to the sudden wedging of the foreign body through them. This is well illustrated in the bursting effect of the modern small-calibered projectile upon the skull, as was exemplified by a case occurring at Fort Sheridan not long ago, in which a sentry fired upon a fleeing prisoner at close range. In that case the skull was shattered extensively. I will state, however, that the deductions drawn from that case were somewhat erroneous, in so far as they bear upon the average effect in actual warfare. Wounds received at close range will be comparatively few: most of the wounds inflicted will be at ranges greater than 300 or 400 yards, and less than 1100 or 1200, what may be termed the middle range, not of the small arm itself, but of the average marksman.

The effect of the small-calibered projectile varies greatly with the distance. Many explanations have been offered, some reasonable and some otherwise. An explanation, which I have not thus far seen suggested, is that the flight of the long small-calibered projectile may be compared to the spinning of an ordinary top. The top, at the beginning, has a very rapid rotary and somewhat undulating motion. After it has spun for a short time it settles down to steady work. As it begins to lose impetus it again begins to wobble. In a manner somewhat similar, the long, narrow-calibered projectile, as it leaves the barrel of the rifle, has its maximum of rotary motion upon its long axis, and probably also with this spinning motion there is a slight degree of rotary motion around the point of the projectile as a center. After having traversed a distance of perhaps 300 yards the missile settles down to steady flight. As it begins to lose impetus at long range, it, like the top, begins to wobble somewhat. Obviously, if this hypothesis be true, the explosive effect of the ball would be greatest at comparatively short ranges and its tearing effect greatest at extremely long ranges, while in the middle range its power of clean penetration would be most evident. As most of the wounds will be inflicted at the middle range, clean, punctured wounds will probably be the rule.

Effect of the material of which the projectile is composed.—The nickel jacketed, German silver coated, or steel cased bullet, other things being equal, will inflict a cleaner wound than would a lead ball of a similar size; the difference in smoothness and hardness accounts for this. When the ball enters and remains in any part of the body there will probably be a vast difference between the new projectile and the old. Lead does not easily become corroded, and readily becomes encysted in the tissues. The same is not true of the modern projectile, which will, in all probability, become corroded by the juices of the tissues, and give rise to complications incidental not only to the foreign body, but to its plus properties of chemie irritation.

I have by no means endeavored to cover all the various points which might be raised with reference to the relation of modern small arms to military surgery, but I believe I have called attention to the principal lines along which new surgical experiences are likely to be gained in the near future upon the field of battle.

Professor Hebler demonstrated that a small-cal-

bered, rapidly-twisted projectile gives the best results, so far as range and penetration are concerned. The reduction of the caliber has decreased the weight of ammunition fully 50 per cent., the velocity being increased something more than 30 per cent. by the change in caliber alone. The substitution of the new explosive, cordite, for the old-fashioned powder has still further increased the range, velocity and penetrating power of the small arms projectile. The soldier is able to carry twice as much ammunition as formerly.

It is also true, as someone has said, that "we have reached an equation in the proportions of the mass in the rifle and in the projectile, in caliber rifling and twist, in the density of the bullet and in the power of the explosives."

It remains to be seen, however, whether the modern small arm is as dangerous in actual warfare as the old patterns. It also remains to be shown precisely what effects will be produced by the new projectile upon the living human body, in actual practice. Shooting at cadavers, bags of sand, and steel armor plates proves but little as regards the power of the modern projectile when brought to bear upon living armed enemies, with intelligence, caution, cowardice, keenness of vision, and opportunities for concealment as important factors in the problem of war.

GELSEMIUM.

BY H. P. NOTTAGE, M.D.

Attending Surgeon Roger Williams Eye, Ear and Throat Infirmary, Providence, R. I., Member of New England Ophthalmological Society; Member Massachusetts Medical Society, formerly Assistant Editor *Annals of Gynecology*.
PROVIDENCE, R. I.

My attention was called to this drug in a practical way during the winter of 1889-90 when the great epidemic of influenza was with us. I found it so useful then that I have employed it since daily, both in general and in special practice, with quite uniform and satisfactory results. It is such a reliable drug and covers so many indications, having a rather wide range of action, that it seems to me that our northern physicians, especially should be more familiar with its properties and uses.

In the South where it is indigenous, it is well known and widely used. It is especially adapted to fevers of the intermittent and remittent type, when we do not care to use quinin. Now that malaria is creeping up the Connecticut Valley, and spreading over our southern New England States, we shall find this drug exceedingly useful in influenza and all forms of catarrhal fevers, and especially in neuralgia, when there is a tendency to recurrence or exacerbation on any particular day, or time of day. Let any physician stop giving quinin for every cold and try a reliable green root preparation of gelsemium, and I feel quite sure that it will quickly find its permanent place in his medicine case. The dose is small. It is not expensive, and it is certain in its action. The indications for its employment are so clear that it is best adapted for use as a single remedy. In this way we can study its action and watch the results carefully. This leads in time to a more perfect acquaintance with the drug, and we soon come to regard it as an "instrument of precision," so uniform is its action. For example, I may mention the pulse as an indication and compare it with two other drugs. Aconite acts best when the pulse is small, quick and hard;

veratrum viride, when it is large, full and very strong and quick; gelsemium when it is large, full, quick but easily obliterated by pressure. We find this pulse usually in fevers that tend to a stupid, comatose condition. The other two forms of pulse action are usually found in sthenic fevers with great arterial and cerebral excitement, as in pneumonia.

The drug began to be scientifically studied about 1869, but was in use long before that time. It is related that a Mississippi planter who had an obstinate bilious fever, ordered his servant to dig up a certain root from the garden and make a tea of it. He did so and the planter drank the tea and was seized with great muscular prostration, but without stupor. When this left him the fever was gone. He afterward employed it successfully in those forms of fever that occur in malarious communities.

THE PLANT; PREPARATIONS.

Gelsemium sempervirens, Gray, "Man. of Bot.;" *Gelsem. lucideum*; *Lisanthus semp.*; *Gelsemium Nitidum*, Michaux; *Bignonia Sempervirens*, Willd. (?) "Sp. Plant," III, 291.—"The yellow or Carolina jessamine is one of the most beautiful of the climbing plants of our Southern States, ascending lofty trees and forming festoons from one tree to another, and in its flowering season in the early spring, scenting the atmosphere with its delicious odor. The stem is twining, smooth and shining; the leaves perennial, opposite, shortly petiolate, lanceolate, entire, dark green above and paler beneath. The flowers are in axillary clusters, large, of a deep yellow color and fragrant, with a very small fine leaved calyx, and a funnel-shaped corolla, having a spreading, fine-lobed, nearly equal border. The fruit is a flat, compressed capsule divisible into two parts, two celled and furnished with flat seeds, which adhere to the margins of the valves. The plant grows in rich moist soils along the sea-coast from Virginias to the south of Florida. The flowers are said to be poisonous." (U. S. Disp.)

This is an indigenous American plant and has been used mostly in the south and west. In France the root, fluid extract and tincture are used and also an alkaloid gelsemin. The root contains oxalate of lime, starch, gallic acid, a volatile oil, coloring matter, but especially, 1, a resinous substance; 2, gelsemin; 3, gelseminic acid.

The gelsemin obtained by Wormsley is amorphous, has a bitter taste, melting at about 100 degrees C; dissolves with difficulty in water, somewhat more readily in alcohol, and readier in chloroform and ether. Its salts are not crystallizable. Gelseminic acid is identical with esculin, a glucosid found in the horse-chestnut of India (*asc. hipp.*) As chloro-hydrate of gelsemin we have the active principle in crystals. In commerce we find: 1, amorphous gelsemin, an impure resinoid, least active; 2, pure gelsemin, crystallizable as chloro-hydrate, very active. The first form usually appears as a black liquid and is identical in toxic power with the American fluid extract. The second is a whitish-yellow crystalline powder, easily soluble in alcohol and glycerin; soluble with difficulty in chloroform and insoluble in ether. Water at 15 degrees C. dissolves one part of the alkaloid in forty parts of the liquid.

Physiologic and toxic action.—A large dose produces general prostration and paralysis of all the voluntary muscles, while the mind remains clear. The involuntary movements are unaffected. In this stage

dimness of sight is nearly always present to some degree, together with drooping of the eyelids, with much difficulty in opening them. A slight degree of stupor or sleepiness is present, or what seems to be a sluggish mental condition. Next follows partial paralysis of all the involuntary muscles, first the sphincters, then the respiratory and then the heart. During this stage the functions of the brain are not always abolished, but can be aroused by electricity and physical agitation of the body. In other cases a profound stupor is present. In some exceptional cases, when a very large dose is taken, the brain seems suddenly congested and a sort of apoplexy occurs. When death has seemed imminent recovery has occurred under the use of stimulants and galvanism. The nearest analogues to this drug are aconite, veratrum viride, conium and physostigmia.

The first or primary effects of gelsemium are similar to the secondary effects of belladonna. Its sphere of action seems to be the motor side of the spinal cord, the brain and mucous membranes. The sensory nerves are not so profoundly affected as by aconite. Compared with strychnin, gelsemium causes primarily passive congestion of the brain; strychnin active. Like conium and physostigmia it paralyzes nerves of motion, while strychnin and belladonna excites both sets of nerves. Gelsemium produces death by general paralysis and a kind of passive apoplexy, while strychnin causes a tetanic, actively congested state of the cerebro-spinal centers. This may be said to be the primary action of these drugs. Strychnin and belladonna cause by their secondary action, general paralysis similar to the primary effect of gelsemium and physostigmin.

THERAPEUTICS—DOSAGE.

Disorders of the circulation, headaches.—I have found it useful in the headaches which occur at the menopause, together with "flushings;" the head and body hot. Sometimes the flushings are followed by profuse perspiration. Gelsemium controls these symptoms very well in 2 or 3 drop doses every three hours.

Insomnia.—While the drug is by no means a direct hypnotic, yet it will relieve those patients who are plethoric, and whose faces indicate cerebral excitement following mental and physical exertion.

Sunstroke.—When there is active cerebral congestion gelsemium is indicated. *Meningitis*, in children especially.

Uterine engorgement and vesical irritation.—It seems to quiet the circulation in the pelvic viscera.

Spasmodic dysmenorrhea.—Exceedingly useful. One dose of 5 to 10 drops will often give more relief than opium, and leaves no after-effects.

Rigid os uteri.—Ten drops of the tincture every half hour until relaxation.

Dysuria and spasmodic retention.—After one or two doses the catheter can be dispensed with.

Muscular spasms.—Useful in all forms wherever occurring.

Vaginismus.—In cases of a purely nervous character.

Gonorrhea.—In the first stages when there is the usual local excitement, doses of 5 drops every three hours favors micturition and favorably influences the disease. When the discharge becomes thick the other usual remedies must be used.

Mucous membranes.—It is especially adapted to acute inflammations of mucous membranes. It does not act on the parenchyma of organs, but may be useful

in the congestive stage because of its action on the cerebro-spinal nerve centers that govern circulation. Before pathologic changes have occurred its influence is powerful for good. We find it especially adapted to the first stages of colds and local congestion of the lungs and bronchi. For ordinary colds quinin can not be compared with gelsemium, while for influenza it is a most satisfactory remedy to control the fever and the aches and pains. For the prostration give strychnin, also preferably in the form of the arseniate. During the great epidemics of 1890 and 1891, I treated many cases of this disease without quinin and only an occasional dose of an antipyretic, and the mortality was light. I remember but five cases in the two years that died from the disease or its complications. If I saw the patient within the first day or two I immediately gave 5 drops of the tincture of gelsemium and then mixed from 10 to 20 drops in 118 c.c. of water and ordered a teaspoonful to be given every half hour until the pains were relieved. This occurred in the majority of cases in about two hours. The next morning the patient was nearly free from pain. On the third day they wanted to get out of bed. I almost always gave .0007 grams of arseniate of strychnin every two hours, and my patients recovered in good condition. When called to cases that had been sick a week or more I still found the drug useful, but never failed to give the strychnin and stimulating food. No alcoholic stimulant of any kind was used, as it did not seem to be required. There is a certain variety of cold for which gelsemium is as near specific as any drug can be. The patient feels cold chills running up the back. A clear watery fluid runs from his nose. Now give the gelsemium and the next morning the cold is gone.

Acute catarrhal enteritis.—Astringents are too irritating for an acutely inflamed mucous membrane. Gelsemium was used extensively during the late war for acute diarrhea, and it has served me well. For this class of cases I used bismuth until I came to know the virtues of gelsemium.

Nervous system.—In discussing remedies the question of dosage is usually lightly passed over. Although I shall leave for the last the various methods of handling the remedy that I have found most useful I desire here to contrast the dosage that I have found effective in two conditions: vertigo and chorea.

Vertigo.—This is only a symptom; but when I have not succeeded in locating the cause in the stomach or liver gelsemium has had good effects in exceedingly small doses. Let me illustrate: Mr. T. came to me in January complaining of dizziness, so severe that he had not been able to work all the fall and winter. He tried the usual treatment of good physicians. I found that he had chronic nephritis with $\frac{1}{4}$ per cent. albumin and hyaline casts in the urine. I gave him at first 2 drop doses of the tincture every two hours. This rapidly made him worse and he had to lie down. I ordered it discontinued and asked him to report when his condition should be the same as before taking the medicine. In three or four days he came and said he was about as dizzy as he had formerly been all winter. I then diluted the tincture with alcohol so that every drop of the dilution contained 1/100 drop of the tincture. He took 2 drops of this every two hours. In a week he was at work, free from dizziness. He worked about six months and had another attack, not so severe as the first. The same treatment relieved him. Several months after that he had another slight

attack which was quickly relieved. He has been under observation two years and is still at work. In another case where I could find no cause for the vertigo it was promptly relieved by similar doses. I have used it in aural vertigo with some success.

Chorea.—When bromid, arsenic and the usual remedies fail try gelsemium in 2 to 5 drop doses four times a day. This dose will give satisfactory results for ordinary cases, but must be varied for severe ones, or when the patient is frail and weak. A case cited from "Webster's Dynamical Therapeutics" will illustrate. "The patient, a bright boy, aged 11, has been the victim of chorea for over a year. He was under the treatment of a physician of world wide reputation for six months. He improved under his treatment, was brought home and within a week was as ill as ever. He was unable to stand alone or feed himself. This case was given, June 3, 2 drops of the tincture four times a day. July 5 he was dismissed cured, having taken in all about 4 c.c. of gelsemium. The child has been under observation for a year and there has not been the slightest return of the disease."

Pain.—Gelsemium is curative for pain that is neuralgic in character, such as ticdouloureux, intercostal neuralgia and sciatica. It is not so useful as other drugs in pure neuralgia but if there is arterial excitement, local congestion, or malaria, it acts very satisfactorily. Jurasz (Heidelberg) treated with the tincture (5 to 20 drops several times a day) five cases, of which three were facial neuralgia, one sciatic and one brachial. The last case had continued a year and a half, the other cases from several days to a few weeks. In every case the cure was prompt. Dr. Pelz had good success in trigeminal neuralgia, especially dental. He followed the indications laid down by Spencer Thompson, who gives 20 to 25 drops of the tincture and repeats this dose if after one and a half hours the pain has not ceased. This dose I am inclined to think would be rather large for the green root tinctures.

The gelsemin in the Chanteand granules is the amorphous variety and hence the doses can be repeated frequently without fear of any sudden toxic effects that might follow one large dose in a susceptible patient.

Infantile convulsions.—A better remedy could hardly be found. As a preventive when the child's face is congested and it is nervous it acts well. By combining it with passiflora I think that a more lasting effect is produced.

Action on the eye.—The ocular phenomena resemble those which conium produces. Ptosis is more marked than loss of accommodation, and diplopia is far more frequent. This seems to depend on loss of power of the sixth nerve, which dominates the rectus externus, and which is especially affected by this drug. Tweedy found that the alkaloid, dropped into the eye, caused at first only ciliary congestion with slight contraction of the pupils. Then dilatation ensued, whereupon the hyperemia disappeared. I have found it useful in controlling the pain and inflammation of both iritis and keratitis.

Case 1.—J. K. H. had a severe attack of iritis. He said that even when he buried his head in the pillow he could see light, which was exceedingly painful. He groped his way to a vial of gelsemium, that I had given him, and poured out about ten drops and took it in one dose. In a few minutes he began to experience relief, and in a half an hour was able to go to his physician's office about three miles from his residence.

Case 2.—Mrs. H. had for about two months an acutely in-

flamed eye. I found an ulcer on the corneal margin. I prescribed both eserin and gelsemium and she obtained great relief from pain in a few hours. The eserin may have assisted but I think that the relief from pain was largely due to gelsemium.

Retinitis albuminurica.—I have found gelsemium useful when coming on during pregnancy.

Serous choroiditis.—It has been reported to be very useful in amaurosis, when the pupils are dilated, the accommodation is disturbed and the lids feel heavy.

Southern physicians report it valuable in cases of intense periodical congestion, from masked ague.

While gelsemium would appear to be indicated as a mydriatic because of the short duration of the paralysis (about two hours), yet because there is a tendency to vomiting it is not so useful as the other agents more commonly used.

Otalgia.—I have found it useful for earache in children, without even the assistance of any local application.

Nose and throat.—Gelsemium arrests glandular secretion and catarrhal inflammation; spasm of the glottis; spasmodic croup and spasmodic asthma.

DOSAGE.

I shall attempt to indicate the methods of using the remedy that have been successful in my hands.

The drug has a different range of action according to the size of the dose, and this is what makes it such a polychrest among remedies, and yet because of a certain limited range of action it is not a cure-all. Any drug that controls arterial circulation through the nervous system and does not greatly affect the heart, and which also changes secretion and affects muscular action will necessarily meet many indications. Gelsemium does all this, and because of its certain action and adaptability for quick dispensing it should be more widely studied.

The preparations that give the best results are the green root tinctures made by reliable firms. The granules of Chanteand are convenient but I have not had any experience with them.

Lethal dose.—The lethal dose of the crystallized alkaloid is from 30 to 60 milligrams; and of the amorphous, 300 to 600 milligrams; the dosimetric granules are of the amorphous variety. I do not think that the alkaloid contains all the virtues of gelsemium, judging from reports.

Small dose.—I have used from 1/100 to 1/50 of a drop of the tincture, only in cases of vertigo. I am aware that others prescribe it for a variety of symptoms, but I have observed that the physicians who are most successful with the remedy and who are satisfied with its action, in the conditions already discussed, use the medium and larger dose.

Medium dose.—A medium dose is from 1/10 of a drop to 5 drops, and acts well in the following conditions, but it should be repeated from a half hour to an hour or two; in hot flushings, enteritis and chorea given in medium to large doses; insomnia, meningitis (also large dose); uterine and vesical irritation and pain, given in medium dose, preceded sometimes by one large dose; gonorrhea, la grippe, infantile convulsions and irritability during teething, iritis, keratitis, retinitis albuminurica, serous choroiditis.

Large dose.—A large dose may be said to be 10 drops or more. It should be given with the same care as veratrum viride. It is used in sunstroke, meningitis (sometimes), rigid os uteri, muscular spasm, spasmodic dysmenorrhea, pain, iritis and keratitis if severe, and otalgia.

FORMALDEHYDE DISINFECTION.

BY WM. ROYAL STOKES, M.D.

BACTERIOLOGIST TO THE HEALTH DEPARTMENT AND LECTURER ON BACTERIOLOGY, BALTIMORE MEDICAL COLLEGE.
BALTIMORE, MD.

Although formaldehyde was first obtained by von Hoffman in 1866, who made it by passing the vapor of wood alcohol over finely divided platinum, yet its practical use as a disinfectant was not applied until quite recently. Aronson¹ published the results of some work in 1892, showing that formaldehyde gas would destroy pathogenic bacteria, even when these organisms were exposed superficially in large rooms. Under such circumstances he found that when such bacteria as the staphylococcus pyogenes aureus, the streptococcus, the bacillus pyocyaneus, the typhoid bacillus, the diphtheria bacillus, the anthrax bacillus and the tubercle bacillus were exposed to the action of the gas in sufficient concentration, these germs were destroyed. Sterilized pieces of silk thread, gauze, linen and wool were soaked in bouillon cultures of these organisms and then placed in various portions of the room. Cultures from these materials which had been exposed to the gas remained sterile and inoculation experiments proved negative.

Kinyoun's² exhaustive experiments also show that the generation of formaldehyde under pressure will destroy bacteria even when covered by such materials as blankets and sheets. He killed such organisms as the typhoid, the anthrax and the diphtheria bacillus, even when covered by ten layers of blankets or thirty-six layers of new cotton sheeting. He thinks that such materials as curtains, carpets and bed coverings can be disinfected by means of this gas, but that the interior of books, mattresses and pillows are not generally reached by the means usually employed. His methods will be mentioned under a general consideration of that subject.

The studies of Harrington³ are also of interest. He found that culture plates exposed to the air of a large room for twenty-five minutes contained from forty to seventy colonies of non-pathogenic dust organisms and from twenty to forty colonies of the usual micrococci found in the pus; particularly the staphylococcus aureus and albus. After the room had been disinfected by formaldehyde the plates which were exposed to the atmosphere remained practically sterile. Cultures taken from the dust of the room before disinfection, gave abundant growths, but after exposure to the gas the dust was found to be sterile, showing that this agent destroyed the organisms present, both in the air and in the dust of the floor. The above investigator also concludes from his experiments that formaldehyde is a good surface disinfectant of such bacteria as the staphylococcus aureus, the typhoid and the anthrax bacillus.

McShane and Stokes also found formaldehyde to be a serviceable disinfectant. Cultures of the staphylococcus aureus and the typhoid, the diphtheria and the anthrax bacillus were constantly destroyed when superficially exposed. The organisms, when covered by from four to eight layers of blankets, or even when placed in the middle of a straw mattress, were killed when subjected, by means of the Trillat apparatus, to 1 liter per 1000 cubic feet. Trillat⁴ was also able to destroy such organisms as the tubercle, the diphtheria, the typhoid and the anthrax bacillus by means of his apparatus.

Experimental report.—A series of investigations

was made by Health Commissioner McShane and the writer at the Health Department of Baltimore in order to determine the utility and effectiveness of formaldehyde gas and the power it possesses of destroying bacteria under conditions usually found in ordinary households. The object in view was the determination of its value in the surface sterilization of rooms as well as its power to destroy bacteria in the deeper portions of such absorbent articles as mattresses, blankets and other household articles.

In all of the experiments we endeavored to place the cultures in such positions as would best represent the conditions in a room in which a communicable disease had existed. We selected the organisms of diphtheria and typhoid fever as fairly representative of the usual diseases with which one might deal, while the staphylococcus pyogenes aureus was used on account of its universal distribution throughout nature. The anthrax bacillus was also chosen because of its powers of resistance to the usual agents of destruction. The first series of experiments was performed with the Schering formalin disinfectant. This apparatus practically consists of an alcohol lamp which burns under a reservoir containing a number of solid pastils of polymerized formalin or tri-oxymethylene. The heat of the flame causes the pastils to vaporize and formaldehyde gas is given off.

Following out the work of Aronson, we used 75 1-gram pastils for a room of 1248 cubic feet. This was said to be enough for a thorough surface disinfection, being about one gram for every fifteen cubic feet of space.

The following materials containing bacteria were exposed in the rooms: No. 1, the staphylococcus pyogenes aureus dried on linen and then placed in a Petri dish; No. 2, diphtheria bacillus dried on linen and attached to the wall about three feet from the floor; No. 3, staphylococcus pyogenes aureus dried on linen and attached to the wall three feet from the floor; No. 4, typhoid bacillus dried on linen and attached to the wall midway between the floor and the ceiling; No. 5, anthrax bacillus dried on linen and attached to the ceiling; No. 6, two specimens of the anthrax bacillus dried on linen and attached to the wall four feet from the floor; No. 7, anthrax dried on linen and attached near the floor. All of these specimens were prepared from twenty-four hour cultures of the above mentioned organisms.

As soon as the room was opened the materials were removed and portions were at once placed upon slanted glycerin-agar tubes by means of sterile forceps. All these remained sterile, showing that the gas caused a thorough surface disinfection of the room.

A series of experiments was also performed at the same time, in order to study the penetrative properties of this gas, when generated by the apparatus just described, and for this purpose bacteria were exposed under the following conditions: No. 1, bouillon culture of the anthrax bacillus, one millimeter deep, in a covered Petri dish, wrapped in five layers of plain cotton; No. 2, linen with dried culture of the staphylococcus pyogenes aureus in eight layers of towels; No. 3, moist culture of the staphylococcus pyogenes aureus on linen, in eight layers of towels; No. 4, anthrax bacillus dried on linen, in a Petri dish wrapped in one layer of cotton; No. 5, moist linen containing the diphtheria bacillus, in four layers of plain cotton. Each layer of the cotton was about one centimeter thick.

Cultures from all these materials gave luxuriant growths, showing that the gas was not able to act by penetrating the meshes of plain cotton or towels. Control of cultures also grew from the above organisms dried on the linen slips which were not exposed to the atmosphere of formaldehyde gas.

These results about accord with those obtained by Aronson, who found that this apparatus would practically destroy such bacteria as the staphylococcus pyogenes aureus, the streptococcus, the bacillus pyocyaneus, typhoid and diphtheria bacilli, and the tubercle bacillus when superficially exposed. When bacteria were placed in the compressed pockets of a coat, or in the middle of a pillow, no destruction of the organisms took place, and he considers steam a better disinfecting agent for such thick material. We are convinced by personal trial that this apparatus will cause satisfactory surface disinfection in ordinary dwelling rooms, when one gram per fifteen cubic feet is vaporized.

We next turned our attention to a formaldehyde generator which might destroy bacteria in the depths of such bulky structures as mattresses and blankets. For this purpose we chose the Trillat autoclave. The same room was used, and in the first series of tests gas was evolved at a pressure of two atmospheres for one hour, and about one liter was evaporated.

The following substances containing bacteria were exposed in the room for twenty-four hours:

No. 1, diphtheria bacillus dried on linen and attached to the wall; No. 2, typhoid bacillus, same conditions; No. 3, staphylococcus pyogenes aureus, same conditions; No. 4, anthrax bacillus, same conditions. These were all dried in a vacuum and then exposed at varying heights from the floor to the ceiling. No. 5, staphylococcus pyogenes aureus dried on linen and then covered with eight layers of blankets; No. 6, anthrax bacillus dried on linen and then covered with eight layers of blankets; No. 7, the aureus on linen, in a sealed envelope, in the middle of a straw mattress; Nos. 9, 10 and 11, typhoid, diphtheria and anthrax bacilli in mattress, just as No. 7.

Cultures from all of those substances with the exception of No. 6 remained sterile, but this organism survived the disinfection and gave a well marked growth. Control cultures made from the above mentioned organisms dried on linen and not exposed to the gas, showed well marked growths after twenty-four hours.

A second series of experiments was also performed in the same room with the Trillat autoclave, the gas being generated for an hour and a half at the pressure of two atmospheres and one and a half liters of formochlorol being evaporated.

The following test organisms were exposed for twenty-four hours: No. 1, a moist cloth saturated with a bouillon suspension of the staphylococcus pyogenes aureus kept moist in a Petri dish; Nos. 2 and 3, typhoid and anthrax bacilli, exposed under similar conditions to that of No. 1.

A number of bacteria were placed in the middle of a straw mattress. Openings were made in the ticking in order to introduce the specimens. The mattress was then reversed so that the openings were closed by contact with the floor. This caused the formaldehyde to penetrate the ticking as well as the inside straw.

The following objects were placed in the middle of the mattress: No. 4, aureus on moist linen, in a cov-

ered Petri dish; No. 5, three specimens of the aureus dried on linen and placed in a sealed envelope; Nos. 6 and 7, typhoid and anthrax bacilli, exposed under conditions similar to No. 5, three specimens of each; No. 8, typhoid bacillus dried on cloth and placed in a closed Petri dish. Bacteria were also placed between a varying number of layers of a blanket. No. 9, two specimens of the anthrax bacillus dried on linen, in sealed envelopes, under one layer of a blanket; No. 10, same as No. 9, under four layers of a blanket (above and below); No. 11, staphylococcus pyogenes aureus dried on linen, in a sealed envelope, under eight layers of blanket (above and below). Several specimens were also placed in the pockets of a coat. No. 12, typhoid bacillus dried on cloth and placed in an envelope, in an outside pocket of a coat, pocket then closed; No. 13, aureus, same as No. 12; Nos. 14, 15 and 16 were the aureus, the typhoid and the anthrax bacillus dried on linen, and attached to the wall midway between the floor and ceiling; Nos. 17, 18 and 19, aureus, typhoid and anthrax bacillus dried on linen, in a sealed envelope and attached to the wall.

Cultures from all of the objects above mentioned, with the exception of No. 3, remained sterile. Control cultures from linen not exposed to the gas grew luxuriantly. The results, therefore, show that not only could complete surface disinfection be easily obtained, but that germs in mattresses, envelopes and blankets could also be destroyed both in moist and dry conditions. Although we believe that the hangings and ordinary paraphernalia of a room can be disinfected by this method, we think that steam should be used for such bulky things as mattresses, etc.

The next series of experiments was performed with the apparatus called the Sanitary Construction Company's regenerator. About one liter of formalin was generated in thirty minutes, the gas entering the same room through the keyhole. The room was closed for twenty-four hours, and cultures were then made from the following substances which had been exposed to the gas. The results follow: Anthrax dry, on wall, two cultures, no growth; typhoid, dry, on linen, on wall, no growth; diphtheria, on linen, on wall, no growth; staphylococcus pyogenes aureus on linen, on wall, no growth; typhoid in pocket, on linen, in envelope, one no growth, one growth; aureus in pocket, on linen, in envelope, growth.

The following cultures were placed in the middle of a straw mattress: Anthrax moist, on linen, growth; anthrax dry, on linen, three cultures, no growth; diphtheria dry, on linen, in envelope, two growths, one sterile; typhoid in envelope, dry, on linen, one no growth, one growth; aureus dry, on linen, in envelope, two growths.

Between folds of a blanket: One layer of a blanket, diphtheria on linen, in envelope, two no growth; two layers of a blanket, diphtheria on linen, in envelope, one no growth; four layers of a blanket, anthrax and diphtheria on linen, in envelope, anthrax no growth, diphtheria growth; eight layers, anthrax no growth, diphtheria, typhoid and aureus showed a growth: moist typhoid, on cloth, in dish, under four layers, growth; moist aureus, on cloth, in dish, in mattress, growth; moist diphtheria, on cloth, in dish, under two layers of a blanket, growth; moist anthrax, on cloth, in dish, in the room, growth. All controls on cloth grew. Some experiments were also per-

formed in order to determine whether a cloth, which had been exposed to an atmosphere of the gas, would absorb enough formaldehyde to prevent the growth of bacteria when the cloth was first smeared on the tube of slanted agar. Upon opening the room, pieces of cloth were taken at once and rubbed over culture tubes. These were at once inoculated with cultures of the germs just mentioned, and the tubes thus treated showed well marked growths in twenty-four hours, showing that no appreciable amount of gas was retained by the linen.

Although this method seems to cause satisfactory surface disinfection, yet we believe that such bulky materials as pillows and mattresses should be steamed.

Methods of manufacture.—The gas is usually generated for disinfecting purposes by means of two different systems. The first system consists in the vaporization of solid pastils of polymerized formaldehyde, or paraform. These, when heated, are entirely converted into the gas, and they are generally used in the Schering lamp, which simply consists of a large metal receiver, under which is placed an alcohol lamp. Each pastil contains one gram of solidified formaldehyde, or paraform, and the complete surface disinfection of the room will depend upon the amount of gas which is generated, or in other words upon the number of pastils used. Aronson found that two grams (about thirty grains) for each cubic meter (thirty-five cubic feet) was necessary for complete surface destruction of bacteria. These results were confirmed by Harrington, McShane and Stokes, and while both Harrington and Aronson found that smaller amounts of paraform would not cause thorough surface disinfection.

In the second system, the gas is evolved by means of heat from a 40 per cent. solution, called formalin. This is generally placed in a strong metal boiler, together with an equal quantity of a 5 per cent. solution of calcium chlorid. The chlorid of calcium prevents the water present from being given off with the formaldehyde gas as steam, thus avoiding polymerization, or the deposit of dry powdered tri-oxymethylene. This powder is not very germicidal and is therefore not desirable as a deposit. This boiler is then heated by means of a kerosene lamp, and the gas can be introduced into a room through the keyhole, by means of the wire tube leading from the cavity of the boiler. The pressure generally used may vary from forty-five to seventy-five pounds, according to the apparatus used.

The apparatus devised by Dr. Kinyoun for the United States Marine Hospital Service will evolve about 1450 liters of the gas from one liter of the formalin. The Trillat apparatus is somewhat similar in construction and should produce about the same amount of gas from the liquid formalin. Kinyoun found that when the gas was introduced into a room in quantities equaling from 1 to 2 per cent. of the total capacity of the apartment, that a thorough surface disinfection took place. Bacteria wrapt loosely in various materials were also destroyed, but when tightly wrapped in many layers of coverings, the bacteria were not killed.

In order to cause a surface disinfection by means of such autoclaves as those described above, about 2/5 of a liter should be used for every 1000 cubic feet of air space in the room. It is better to use too much than too little, and a safe rule to work upon might be the use of 500 cubic centimeters, or 1/2 a liter for every 1000 cubic feet of space.

In the Kinyoun apparatus the pressure is raised to ninety pounds and the gas is then allowed to escape into the room until the pressure is reduced to five pounds. It is then heated again to the same degree of pressure; and the gas is again allowed to escape from the boiler into the room. Two heatings usually suffice to liberate all the gas. In the Trillat autoclave the gas is freed from one liter in one and one-half hours, or from three liters in generally only two hours. The pressure is kept at three atmospheres, or forty-five pounds, and when it falls below two atmospheres and the temperature rises above 135 degrees C. the operation should cease.

The generator of the Sanitary Construction Company allows the formalin to enter a red hot copper coil, and this intense heat liberates the gas, which is conducted into the room through the keyhole of the door. About one liter of formalin can be evolved in thirty minutes. Harrington's experiments showed a surface disinfection with this lamp, when 500 c.c. or one-half liter was used for every 1000 cubic feet.

Over 225 samples of wool, cotton, leather, hair, fur and silk were exposed to solutions and saturated atmospheres of the gas without changing these materials, and Kinyoun also observed that the colors remained practically the same. Copper, brass, nickel, zinc and gilt were not affected, but iron is attacked and should be protected by paint or varnish if exposed to the gas. The fumes of the gas are best neutralized by exposure to ammonia fumes.

It might be well to add that although formalin is destructive to bacteria in solutions of 1/2000, yet the amount of formaldehyde gas which is given off from the watery solution is not able to destroy bacteria in rooms or even smaller spaces. This was proven by Reik⁵ and Watson, who caused the evaporation of formaldehyde from large quantities of formalin in a box containing one cubic foot of air space. The germs exposed were not destroyed in any practical length of time.

It must be confessed that some apparent discrepancies can be found when one compares the work of different observers, but these are often caused by the different conditions under which individual investigators have worked. There is still a wide field open for many practical investigations, and further work upon formaldehyde will doubtless give us many more explicit and needful directions. The practitioner can always determine whether a room has been properly disinfected by simply moistening a piece of sterile linen with a culture of bacillus prodigiosus and placing it in a sterile, open test tube. If exposure to the gas destroys the germ a culture from the linen will not give the characteristic red growth of the organism. In order to obtain satisfactory results every crack and opening of the doors and windows should be carefully closed with wet cotton or adhesive plaster, and not the slightest chance should be given for the formaldehyde to escape. Otherwise the attempts at disinfection will be useless.

The prevention of the spread of communicable diseases.—Although most of the authorities seem to believe that formaldehyde is not able to entirely penetrate very bulky or compact structures, yet they all agree that its action as a surface disinfectant is very satisfactory, and this is just what is needed in order to render other usual precautions of any avail. The mattresses and pillows can be steamed, but the room itself, the hangings, and even the articles of

clothing, if hung up and not packed tightly together, can be rendered non-infectious or free from pathogenic bacteria.

One of the most valuable applications of the formaldehyde method is its use in disinfecting rooms which have previously been used by consumptives. The dust from such rooms has been known to kill guinea pigs, and clinical experience has also shown that infected rooms, especially in large institutions, have often been the real cause of many successive cases of pulmonary tuberculosis. It is believed that environment and not heredity is at the root of many of these cases, and the spread of this disease can be greatly limited by the use of this method.

Although we do not know what causes scarlet fever, yet reasoning from analogy we can conclude that the use of formaldehyde will destroy the infectious materials which have been left in the rooms of patients suffering from the various exanthematous fevers. Diphtheria is generally spread by the direct transference of the diphtheria bacillus from one mouth to another, often through an intermediate infected object. Since Wright,⁶ however, has demonstrated the presence of virulent diphtheria bacilli in cultures taken from the dust of the shoes of nurses in diphtheria wards, a thorough disinfection of the rooms which have contained such cases should always be practiced.

The attempts to disinfect such bulky structures as mattresses and pillows by formaldehyde have not been very successful and these can be better treated by means of the Doty⁷ steam vacuum chamber. Sprague⁸ has performed some experiments, however, which show that clothing can probably be entirely disinfected by means of formaldehyde. He used the Kinyoun-Francis apparatus, which consists of an iron cylinder with a capacity of 1090 liters. This is connected with a vacuum apparatus and a formaldehyde generator. After first causing a vacuum, the gas is introduced in quantities varying from 5 to 20 per cent. of the total air space. The destruction of many bacteria, placed in mattresses, pillows and even between the leaves of books, convinced the experimenter that articles of clothing and bedding could be properly disinfected if simply placed upon the racks which the iron disinfecting chamber contains.

In conclusion, I believe that the votaries of preventive medicine are at last to be congratulated in possessing a substance whose sulphurous-like fumes will destroy pathogenic bacteria.

ERYTHOXYLON COCA AS A HEART TONIC.

BY EPHRAIM CUTTER, M.D., LL.D.,

NEW YORK, N. Y.

After the 1871. San Francisco, meeting of the AMERICAN MEDICAL ASSOCIATION, I went to the Yosemite Valley and ascended the Cap of Liberty, 12,500 feet above sea level. I remember the ascent, which was so steep that I had to pull myself up by the bushes! The diminished atmospheric pressure was such that I could not climb more than forty feet at a time. My pulse ran so high that I could not

count it. My heart beat so violently that I felt it would stop if I did not pause, and my whole body was bathed in sweat. As my heart was somewhat enlarged and so weak that its usual beats were forty per minute, I suppose I ran an imminent risk of losing my life, but as a result I had herpes zoster. This California mountain experience helps me to understand how climbers have vertigo on the summit of the Andes—about the overwork and fatigue of couriers traversing mountains difficult to travel—how such persons have been toned up and refreshed before, during and afterward by the coca tonics, and how Dr. Beverly Robinson could say that coca is a heart tonic.

But for coca the South American miner would weaken at his severe labor. "Negroes can not work in the Peru mines. They all die. Only the natives can endure, and even then it is necessary to relieve them often and that they should chew coca." (Lanquerne.) "When the Indian has a good supply of coca he undertakes, without the slightest fear, the most difficult and the longest voyages." "At the siege of La Paz, in Bolivia, 1781, most soldiers famished, and, put on forced marches, died, save those who used coca leaves." Dr. Liebermann, Surgeon in Chief of the French Army, says that he has found coca very successful in long tedious campaigns. Dr. Scaglia speaks of the great benefit from coca where the muscles have lost their tone and vigor.

The heart is a muscular engine indispensable to life. Severe muscular exertion taxes the heart to supply force. It is an autonomic organ. As the heart is covered with nerve ganglia and connections, it may be said to cardiate as the brains cerebrate.

Heart failure is a term lately become fashionable in death reports. Whether the term is correctly used or not, physicians should carefully study all agents that strengthen the heart. Strictly "heart failure" means failure from lack of nerve force. Cut the sympathetic nerve and the heart would fail, the nerve section having been the prime cause, but the heart has intrinsic powers from its own nerves. When a medical student I removed the heart of a snapper turtle and twelve hours after it had not ceased to beat. Its dynamis must have come from the cardiac plexuses.

Heart failure certainly does not mean a cause of death where a foreign body, as a knife or bullet, has made the heart fail; nor where fatty degeneration, atheromatous or calcareous deposits, valvular lesions, atrophy, hypertrophy, endo- or pericarditis, etc., exist, though these complicating neurasthenia of the heart, will help on its failure. It is time that the idea that heart diseases are beyond cure was abandoned. They are as amenable to treatment as scarlet fever.

Coca, direct action.—Mantegazza says the coca stimulates the heart. He increased his pulse from 65 to 124 by a dose of 55 to 74 c.c. Gazeau and Moreno corroborate this. Dr. Beverly Robinson says, "among well known cardiac tonics and stimulants for obtaining temporary good effects, at least, I know of no drug quite equal to coca." The writer has found coca to give tone and relief to a weakened heart almost immediately.

Coca, indirect action.—Back the heart with a good stomach and you strengthen it. If you disbelieve this, starve until you are faint and then eat a good beefsteak, which is the best food heart strengthener. According to Boerhaave, coca is a food. He states

"that the saliva charged with all the bitter and mucilaginous principles of coca, carries to the stomach, in addition to vital strength, a true nutritive, which is digested and converted into an abundant chyle and is then converted into the material necessary to sustain the human body," that is, it sustains the heart as beef does. Weddell says that an Indian who chewed coca leaves and worked hard all day without food or drink, at night ate as if famished, devouring in one meal food enough to last him two days. In this case coca gave an increased power of digestion and hence more sustenance for vitality. These things being so, coca should be more used in heart failure from direct weakness, and in many cases might well replace the conventional digitalis, which advances the treatment of heart diseases no more than it was forty years ago.

According to Dr. Laffont, the action of coca's active principle on the sympathetic nervous system causes, 1, an augmentation of the functional activity of all the muscles of organic life; 2, excites functional action of the cerebral and spinal nerve centers, increasing intellectual and muscular activity; 3, causes an action on the protoplasm of the extremities of the sensory nerves, whereby they cease to transmit impressions. One and 2 include the heart and further evidence the action of coca to be a heart tonic.

Intestinal and stomacheic gases are deemed, in America, a prolific cause of functional disturbances of the heart. When relief is not afforded by the removal of gases in excess and long continuance, death from heart failure may occur. The idea is that the cardiac nerve centers are paralyzed and overwhelmed, and fail from absorption of the noxious gases. Water, drunk hot, causes contractions of the muscular fibers of the alimentary canal, even when more or less paralyzed, relaxed or distended and thus allows the gases from the fermenting food to accumulate more and more. In the intestines the peristalsis is downward, but in the stomach it is upward and opens the shortest outlet for the imprisoned gastric gases. Ptizans, so much used, are chiefly hot water. Hot water is a remarkable agent of relief from gaseous cardiac paresis. The dynamogenic action of the active principles of coca on the smooth-fibered muscles added to that of hot water as a vehicle, must be of great advantage in the partial paralysis of the involuntary muscular fibers of the heart.

People will eat fermenting food because it tastes good. Count Rumford and the French believe that all food which is palatable is nutritious. They allow the gustatory to overrule the chemie, histologic, physiologic and pathologic food tests. The heart suffers because most popular palatable foods ferment into gases, which, in excess, are poisonous and probably cause more deaths from "heart failure" not traceable to organic lesions, than any other one predisposition. Sugar is a great gas-maker in the alimentary canal. For this reason, in cases of flatus, the fluid extracts of coca and the coca leaves are preferable, especially in cases of enfeebled digestion, as these preparations exclude the grape and cane sugar fermentations.

Anemia.—Coca is well borne in anemias. It must be a benefit to a heart weakened by the deficiency of blood. Coca does this by promoting the appetite and digestion and by thus making more blood. Good blood-making food must not be omitted. The action of coca has been compared to that of strychnia, one of the very best of heart tonics but dangerous. Of two remedies it is better to use the safer.

Coca in angina pectoris, which is caused by the obliteration, partially, of the coronary arteries, the first that arise from the aorta and supply arterial blood to the heart itself. This obliteration is due to an atheromatous, cystalline or gravelly deposit in the muscular coats of the coronary arteries. These deposits appear as small, white, tough, shining cuboids or diamond shaped bodies made up of cholesterolin or other crystalline matters that should have been eliminated from the body by the urine, feces or sweat. Probably they would have been eliminated had the system possessed water enough to keep them in solution. These arterial deposits mechanically cut off, more or less, the blood supply and thus the cardiac tissues are not properly nourished.

Again, these obstructions produce fatty degeneration of the heart muscles by retarding and impeding the circulation, which is one great cause of fatty ill (English idea).

I believe in the antonomy of the heart—that it knows when its rights are invaded and that the spasms, colic or neuralgia of the heart sometimes arise from its efforts to keep life going on a too small capital of dynamis or vital force, just as intestinal or stomacheic colic comes from food too hard to digest.

The heart has no rest save between its beats. Partially cut off its blood, which is its life, and you weaken it. The weakened muscles are necessarily overworked. All overworked muscles are liable to cramp. Hence the cramp or spasm we call "angina pectoris." The most sensible way to relieve it, is to use the remedies known to strengthen the muscular fibers of the heart and stop eating the food which produces the abnormal crystalline deposits in the arteries. Also use water enough to keep the systemic salts in solution. Coca deserves more attention, as it has been favorably employed from time immemorial with less bad results than tobacco or alcohol by people of reported astonishing longevity, and this favorable employment demonstrated by the physical changes in the body, in its use by the same person from youth to old age. Digitalis has not a less hurtful history than coca.

It is a mistake to regard heart diseases, angina pectoris among them, as incurable. Nature will cure almost any diseased organ or tissues if she has the means furnished by proper food, time, judicious medication, wise expenditure of nerve forces and by the causes (mainly bad feeding) being removed. At the Berlin X International Medical Congress, the writer presented his views of the curability of this class of diseases. The more remedies we can add to the list of heart tonics the better.

120 Broadway.

AN INDIVIDUAL DRINKING CUP.

BY D. LICHTY, M.D.

ROCKFORD, ILL.

Since the universally acknowledged advantages of the solitary or individual drinking cup are so readily recognized the adoption of a cup whose introduction into common and general use would not impose a burden or hardship on the user is an object much to be desired and if obtained to be promptly commended.

It is to be admitted that the agitation on hygienic lines has been most successfully conducted through the medium of the church communion cup, and that the success attending its introduction at this most sacred function has quite generally been satisfactory to those participating and most able to judge. That

an innovation of this kind has many difficulties to encounter and overcome is to be expected, as it invades the precincts of the holiest of ecclesiastic ordinances, besides it introduces a new element of expense that the feebleness and rural congregations are illy able to bear.

The solid silver, silver-plated-gold-lined, aluminum or glass cups in sets of forty or sixty, with accompanying tankards for filling, and trays for carrying, would aggregate an expense almost absolutely forbidding their introduction and use into the outlying missions and stations, where usually more than in many other places such solitary or individual cup would be called for.

The perfectly aseptic use and custody of such sets, too, would require a surveillance difficult to procure in many such remote city as well as country districts, should the necessary funds have been secured for their purchase and introduction. But more essential and far more imperative from a sanitary point of view is the demand for the use of an individual cup for the pupils of the public schools and in the mixed migratory army that throngs along our iron highways. To meet the requirements of these numerous and varied conditions, embodying economy and care, it was suggested to my mind some months since that an individual drinking cup could be made from paper, wood-pulp or fiber so cheaply that the passing of the chalice to another or its second use would not be required. Investigation however revealed the fact that knowing ones would not embark in its manufacture unless the protection of a patent restricted its general manufacture by others, but the fact remains that hygienically such cups would meet requirements in many ways, that no public, chained, iron, or polished silver communion cup would fill. Its suggestion here is to bring it before the tribunal of the profession, and probably the trade, for discussion, approval, adoption or rejection.

The very common use of paper-made packages for containing and carrying of nearly every article of diet from the grocer's counter to the consumer's table, the free use of the wooden picnic or outing plate, the paper napkin, all used but once and thrown away, the manufactured wooden toothpick that passing through many fingers and processes finally finds its way into the teeth interspaces of myriads of mouths daily, all suggest that there could also be constructed from a similar material an individual cup, which should be manufactured under as strict antiseptic precautions and placed on the market as absolutely free from contamination as are our surgical gauzes and cottons, and like them, used but once and discarded. Thus the poorest church communicant in the remotest districts, every traveler and every scholar in public schools or private academy might be the privileged owner and user of an individual drinking cup, though not born with the traditional "silver spoon in his mouth." Such a cup could be spun from pulp or stamped from paper, of varying plain or fancy designs; it could even be made to collapse laterally, to be carried in the vest pocket of the railway or cycle tourist. Probably the size and shape most practicable and familiar would be that of one similar to our one ounce medicine glasses. These could be packed in a limited area, closely "nested" for shipment by mail or express at slight additional expense, wrapped in waxed paper, from whence they should be removed only when to be used. For communion service they could be arrayed in cancelled or perforated trays made of light wood or wire, and

if the cups were made of white paper and filled with the crimson sacramental fluid would make an esthetic as well as sanitary array, at once inviting commendation, the cups, when used, gathered up and consigned to the fire. The cost would scarcely exceed, or equal, the paper plate or napkin and would prove the easy entering wedge to a much-needed, well-recognized and desirable sanitary reform, soon leading on and up, where possible, to more costly and elaborate outfits. To the public school pupil and the traveler they would soon find their way and win their own commendation.

MECHANICAL FEATURES IN OBLIQUE FRACTURES.

Presented at the Fourth Annual Meeting of the American Academy of Railway Surgeons, at Chicago, Ill., Oct. 6-8, 1897.

BY JOHN E. OWENS, M.D.

CHIEF SURGEON CHICAGO AND NORTHWESTERN AND ILLINOIS CENTRAL RAILROADS.
CHICAGO, ILL.

The mechanical features of fractures in general and oblique fractures in particular are apparent from almost every standpoint. The derivation of the word implies the mechanical nature of the injury.

The oblique fracture is always the result of some local strain or injury, varying from a slight to a strong muscular effort or of severe external violence. Whether the local cause be from external violence or muscular action, it is mechanical in nature and that, too, whether the bone gives away at the part struck by direct violence or at its weakest part by compression between two opposing forces, as in fracture by indirect violence. Oblique fractures are prone to cause laceration of the skin by their sharp extremities, rendering the fracture compound. This occurs much more frequently than in the case of transverse fractures. A variety of complications may result mechanically from the sharp ends of the broken bones in oblique fractures, such as an injury to some internal viscus, as in case of oblique fracture of the rib or pelvis; a laceration or contusion of blood vessels or nerves, causing hemorrhage, aneurysm or thrombus of the former and paralysis or irritation of the latter. The mechanical effect of more or less violent contact of the ends of the bones in oblique fractures on nerve tissue is to cause bruising with usually temporary loss of power or permanent loss of power in cases of complete division, unless the divided ends be united or engrafted into the continuity of a contiguous nerve. Some neighboring joint may likewise be perforated by the sharp extremities of the broken bone.

The variety of fracture in question is most common in the extremities. They vary in obliquity, and are often only a degree removed from the transverse. The oblique fracture is dangerous, and the greater the obliquity the greater the probability of laceration of the soft parts, including the skin, owing to the more or less pointed shape of the broken ends. There is also greater difficulty in maintaining such fractured surfaces in apposition and in decidedly oblique fractures, in the prevention of shortening.

A prominent element in the displacement of an oblique fracture is muscular contraction arising from the mechanical damage done to the muscles by means of the sharp ends of the broken bones, and these very emphatically claim our attention in reduction. In cases where the oblique fracture causes an injury of an internal viscus by mechanically piercing or rupturing it, the danger depends more upon the injury to

the internal organ than to the fracture itself, as in fractures of the ischium, pubes or ribs. If the main artery of the limb is extensively torn, a diffused traumatic aneurysm must be the result, and gangrene of the limb will in all probability ensue, and amputation will be the only recourse. In other cases the artery may be only partially torn across, or it may be punctured by a spicule of bone. Traumatic aneurysm, diffused or circumscribed, may form. The internal jugular vein has been injured by the ends of the broken bone in oblique fractures of the clavicle.

For mechanical reasons, in oblique fracture the deformity growing out of the displacement and separation of the fragments is more pronounced. Not only should rough or injudicious handling be avoided, owing to the danger such handling may cause to the soft parts, but great circumspection is required to prevent mechanical damage to the tissues by the sharp ends of the broken bone during the transportation of the patient, during the administration of anesthetics, and also from the violent efforts of the patient himself during delirium.

Finally, in oblique fractures the mechanical effect of the broken bones upon the muscles in the production of spasm, is greater than in cases of transverse fractures.

DISCUSSION.

Dr. W. J. GALBRAITH of Omaha.—The Doctor did not give as full consideration as many of our cases demand in regard to the muscular tissue, that in many instances become entangled or interposed between the ends of the bones in all varieties of fractures, preventing perfect apposition and resulting in serious complications in the way of prolonged irritation, non-union and possibly other more serious conditions. As regards the treatment, each case has to be treated according to the conditions.

THE PATHOLOGY AND DIAGNOSIS OF OBLIQUE FRACTURES.

Presented in the Fourth Annual Meeting of the American Academy of Railway Surgeons at Chicago, Ill., Oct. 6-8, 1897.

BY W. J. MAYO, M.D.

SURGEON CHICAGO AND NORTHWESTERN RAILWAY.
ROCHESTER, MINN.

Frank Hamilton on "Fractures and Dislocations" has been an authority for many years. A monument to his memory, a tribute to the genius of American surgery by a master mind! That it should have stood for more than a decade for all that was known about fractures and that at a time when operative surgery was making its marvelous advance, fractures seemed to have been the one subject upon which the last word had been said, was due to several causes: The older surgeons were anatomists and clinicians, their surgery that of traumatism and tumors. These things they knew well and could tell well; for instance that most readable and instructive little book of Cheever ("Lectures on Surgery"), published several years since, the chapters on fractures being absolutely brilliant. The surgery of the last ten years has been that of expediency rather than necessity and in this rapid advance traumatic surgery has been to a certain extent neglected. The contributions of Allis and Roberts of Philadelphia and McBurney and Stimson of New York, the latter being the author of a special treatise which rivals that of Hamilton, have been most noteworthy exceptions to this general statement.

Aseptic and antiseptic methods have done much for compound, but, until recently, very little for closed fractures.

At this time we are in the midst of a most splendid

advance in the diagnosis of fractures, due to the impetus given by the X-ray, and to the wider scope of the diagnostic incision which modern wound treatment has made possible.

The obliquity of a fracture is often the most important feature and its diagnosis and management may prove to be the turning point as to the ultimate usefulness of the limb. As railroad surgeons, we are vitally interested in this aspect of fractures, as the oblique fracture is characteristic of adult middle life and constitutes the bulk of such injuries both in the traveling public and employes, for obvious reasons. The frequency of deformity after this variety of fracture, interfering with the utility of the member at a time of greatest usefulness, is a source of great pecuniary loss to the company, and in private practice, too frequently, of a malpractice suit against the surgeon. The green stick and transverse fracture of childhood and the senile or pipestem fracture of age are far easier of adjustment.

Mudd concisely says that "an oblique fracture is one in which the line of fracture is at an angle of not less than 10 nor more than 70 degrees to the axis of the bone; it is an intermediate between a transverse and a longitudinal fracture. The surfaces are at such an angle that even if well adjusted there is a disposition to overlapping, and any force tending to shorten the bone, whether it be pressure or muscular contraction, produces displacement with consequent shortening. The fractured surfaces are disposed to slip, one upon the other until there is overlapping." This form of injury is most often due to indirect force and the resulting shortening depends upon obliquity and displacement. Such shortening constitutes the greatest disaster in the femur, three-quarters of an inch or more causes a limp, pelvic droop and compensatory spinal curves. In the upper extremity there is less liability of functional or cosmetic after-results, provided a joint be not involved.

There are some points in the pathology which are of the greatest importance. The formation of callus is not only from the bone and periosteum but also from the soft parts; the lower maxilla, clavicle and ribs having but a small amount of tissue in close proximity have less callus, and the callus formed is most abundant upon the side of the bone where the soft coverings are most plentiful. MacEwen in his work upon bone growth shows that true bone originates from any or all parts of the bone, medullary canal and periosteum. Defective or too abundant callus may, of itself, cause displacement and consequent union with deformity, or from excessive damage to any one element of bone formation the same conditions may exist.

In paralytics and those suffering from certain constitutional maladies such errors in repair are most apt to appear. In rheumatic individuals the disturbances in the soft parts and neighboring joints may be the starting point of a chronic rheumatoid-arthritis, especially at the hip, and Tillman calls attention to the peculiarities of the resulting deformity for which the surgeon is wholly blameless. The influence of chronic inflammation of bone, especially near the epiphyseal line, upon bone growth is noted by Senn. I have seen the tibia elongated an inch by a central abscess in the growing bone. Professor Humphries and Corydon L. Ford have made extensive investigations as to asymmetry of bone length in otherwise normal individuals and the frequency of such abnormalities

should put us upon our guard in the measurement of broken limbs, while the possibility of error due to former injuries should be constantly in mind.

Oblique fractures not infrequently become entangled with the soft parts and union is prevented by the interposition between the fragments of such material. Muscular action constantly tends to displacement of the fractured ends and causes shortening and this is especially marked in the femur. This bone also requires much time for solid union. Cheever says that he has known a fractured shaft of the femur at six or eight weeks, with one-half inch shortening, by injudicious use to gradually slip by, from pressure upon the callus, and give an ultimate shortening of two inches or more. I have seen a similar instance. In children, union is more rapid than in adults, but caution should be used after fracture of this bone in allowing its use.

Dawbarn, in discussing the care of fractures, well says that until the eighth or tenth day union is so incomplete as to render it possible to change the position of the bone ends readily and that until this time efforts should constantly be made, if necessary, to complete the diagnosis or to overcome any existing deformity. Rebreaking of a fractured bone which has united with deformity is followed by slow repair and sufficient time should elapse before putting weight upon the limb to allow strong union and prevent recurrence of the malposition.

Time forbids the discussion of the pathology of fractures or reference to such complications as fat embolism, non-union, ankylosis, etc.

The classic signs of fracture are too well known to require discussion and less difficulty would be experienced if we saw the injury at once, but usually several hours or even days have elapsed before the examination is made and an exact diagnosis may be impossible on account of swelling and, as a rule, an anesthetic should be administered. Crepitus is usually present, but may be absent on account of either impaction or the interposition of soft parts.

Preternatural mobility and loss of function may not be prominent features if only one bone be broken either in the forearm or the leg. Shortening requires careful measurements and, as suggested by Ashhurst, we should use several points of measurement for comparison. A possible asymmetry of the limb should be eliminated. Pain and swelling are not peculiar to fractures more than to other injuries and do more to confuse than to help in the diagnosis. Bipolar pressure would cause more pain in a fracture than a contusion, as pointed out in the *Railway Surgeon* for July, 1897.

Before taking up the new methods of diagnosis by incision and the X-ray, I wish to call attention to the great value of a procedure, credited by Dawbarn to Gerster, in *The New York Polyclinic* for July, 1897, as an aid to the diagnosis of fractures about the elbow joint after swelling has taken place. An anesthetic is administered and a Martin's rubber bandage is slowly applied from the fingers to the shoulder; at the expiration of fifteen minutes, during which time swelling is pressed out, the upper turns are tightened to prevent blood from entering the arm, while the lower turns are completely removed to a point above the joint. By manipulation of the now greatly reduced elbow an exact diagnosis is arrived at and treatment instituted. The swelling soon returns upon the removal of the bandage, but the purpose has been

accomplished. I have had occasion to try this method within a short time and it proved useful.

The so-called "gunstock deformity" or loss of carrying power, so often seen after the common oblique fracture of the lower end of the humerus complicating the elbow joint, has received attention from Allis of Philadelphia and Powers of Denver, and as a result of their labors the diagnosis and treatment of this class of injuries have been greatly improved. Credit should also be given to Roberts for his efforts in behalf of fractures of the lower end of the radius, and to Royal Whitman for his practical observations upon the diagnosis of fractures of the neck of the femur in children (*"Annals of Surgery,"* June, 1897).

Exploratory incision for purpose of exact diagnosis and as an aid in treatment has been practiced occasionally for some years. There is now a marked tendency to resort to this method in many cases of obscure bone traumatism at an early date. McBurney, in an able article on fractures of the humerus complicated with dislocations at the shoulder joint, advocates incision and has invented a traction hook to aid replacement. G. W. Spencer, in the *American Journal of Medical Sciences* for April, 1897, gives a résumé of cases of fracture of the clavicle, exactly diagnosed and treated by incision, and Allis speaks for the open management of certain fractures, in the *"Annals of Surgery"* for June, 1897. At the October, 1896, meeting of the Philadelphia Academy of Surgery, in a discussion of this subject participated in by Deaver, Roberts, Hearn and others, the consensus of opinion was in favor of incision in the diagnosis and treatment of obscure fractures.

Just when should incision be performed? There is no doubt that an immediate incision, before swelling has taken place, renders the aseptic after-management easier to secure. If there is much skin injury with tendency to the formation of blebs and great swelling of the soft parts, incision is fraught with danger of sepsis, and a delay of a few days to obtain a sound skin site for incision is a safe plan, particularly as union of bone does not take place before eight or ten days. In a considerable personal experience I have found the intermediate period a bad time for incision.

The Roentgen ray, as an aid to the diagnosis of fractures, is one of the marvels of the day, and the ability by this means to accurately map out the fracture without removal of the dressings has revolutionized the diagnosis. So common is its use that almost every issue of our medical periodicals contains skiagraphs of bone traumatisms. It is a matter of regret that only in the larger hospitals or cities can it be utilized and unfortunately its revelations at a late date are apt to prejudice a jury in the possible malpractice suit. In the very excellent skiagraphic work of Dr. J. G. Cross of this city I have noticed that the ultimate result is often good even when the bones are not accurately in place.

Leonard Freeman in the *"Annals of Surgery"* for April, 1897, says in this connection, "it must often be true that when we imagine we have placed the fragments of broken bone in perfect apposition they may not be so after all and yet the result be good, nature being capable of smoothing off many inequalities."

Until we can better estimate nature's capacity for repair the skiagraph may cause much needless anxiety, and still more unfortunately for our piece of mind, show us errors in position which the condition of the soft parts will not allow us to safely correct, or the

process of repair may in the occasional case develop rather than prevent deformity. The X-ray may be made to exaggerate the existing deformity or displacement, from carelessness or purposely, and in suits for damage no skiagraphs should be accepted unless made by a disinterested operator.

In an editorial in the issue for Sept. 4, 1897, of the *JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, X-ray injuries are thoroughly discussed and the conclusion drawn that it is rare for serious skin lesions or other ill effects to happen in the hands of careful men, and the rapid improvement of apparatus and technique will soon reduce such misfortunes to a minimum.

DISCUSSION.

Dr. THOMAS B. LACEY of Council Bluffs, Iowa.—I think we ought to give the matter of the skiagraph of a fracture more consideration than we have heretofore. It seems to be an accepted fact that a skiagraph can be easily made to either distort or exaggerate any shadow of a foreign body or of the displaced fragments in a fracture. I have some misgivings as to the use of a skiagraph in cases of oblique fractures for this reason. There are a great many people who think that a surgeon, in treating a mangled limb, must make it as good if not better than it was originally, or else he has not done right. On this basis we are too often apt to be mulcted in cases of malpractice suits, when any competent surgeon who examines the case, after understanding the circumstances, knows that the best that was possible was done for the patient. Personally I dread the oncoming of the skiagraph in these cases, unless the future shall develop greater accuracy.

Dr. J. P. LORD of Omaha.—While I believe that different skiagraphs of the same case will show very differently, yet I do not know that we can set them down as being inaccurate. I think it does show us that the conditions are exaggerated, and that the X-ray will teach us that there is a possibility for a great deal of deviation of bone fragments, although it must be admitted that it gives us a better idea than we ever had before of the extensive separation of the fragments, and this is the point that I wish to make, that we should collect a number of skiagraphs, as we soon will be able to do if we make comparatively general use of the instrument, which we all should do, and with the cheapening of the apparatus it will be within the means of those who practice to any considerable degree, and then we will have something to fortify us against X-ray pictures which might prejudice a jury. We might bring skiagraphs to show that a certain condition was common, and even though there is not a great deal of deformity, a great deal of callus and deviation of the fragments, yet comparatively good results followed treatment, and that this need not necessarily influence the result unfavorably. If the skiagraph influences the result unfavorably it is only what is to be expected, and the good results that are gained, perhaps in an individual case under dispute, are as favorable as could be expected under the circumstances. I believe that we are unnecessarily alarmed about the damage the X-ray may do us, and when we consider the strong advantages it has for us we will make the proper use of this sort of evidence. We may use it as a boomerang to counteract the influence which possibly may be used against us. We should consider this and use the X-ray with that end in view.

Dr. FRED. J. HODGES of Anderson, Ind.—Since the discussion has tended toward the consideration of the skiagraphic phase of the subject it is important to know that existing fractures do not always show and that there are undoubted cases on record in which the radiograph seems to show a fracture when it does not exist. These are two points of extreme importance. It is also important to know that a slight deviation in the angle of the bone to the plate will make a difference and a distortion of the resulting skiagraph. It has occurred to me that the only logical and legal way of bringing this matter before a jury would be to bring the apparatus into court and show the condition of the case with either the fluoroscope direct or with the screen. Not long ago I examined a radius, in which there was no doubt, from ordinary physical examination, as to the existence of a fracture, and yet it took half an hour with the fluoroscope to find it, and authenticated radiographs of that case, taken in half a dozen different positions, would have failed to show the fracture, so that a great deal of refinement in operating these pictures is necessary, as well as a great deal of certainty in the identification of them, and a description of the relative positions from which they were

taken, is going to be necessary in courts of law before the whole truth is brought out about these cases. It is a well-known fact that impacted fractures do not show by the X-ray process, and it is also well known that in perfectly united fractures the new bone is not opaque to these rays, so that in perfect union there is still the appearance of non-union. Those are matters which particularly affect oblique fractures.

Dr. W. L. SMITH of Streator.—In regard to the X-ray I will say that it depends very much on the distance of the tube from the fracture what picture you get; also how fine you may cut the lines with the tube. I believe that if you have a funnel made of lead and allow the tube to sit on the top, then you can define very clearly the parts that are shown underneath. It does not take any longer with a funnel made of lead, which the X-ray will not penetrate at all, and you have nothing on the outside showing. So if you have a funnel about six inches high and eight inches around, it will show very clearly what you desire to see. I believe the surgeon is the only man to place the limb so as to show what he wants to see. If a bullet is on top of a bone it will not show; if it is in the bone it will not show; if it is on the side it will show and in my case I found the bullet behind the head of the tibia. If you will try a funnel made of lead, I believe you will find the foreign body every time.

TREATMENT OF OBLIQUE FRACTURES.

Read before the Fourth Annual Meeting of the American Academy of Railway Surgeons, held at Chicago, Oct. 6-8, 1897.

BY C. K. COLE, M.D.

HELENA, MONT.

To discuss the treatment of oblique fractures and not consider "retentive apparatus" and mechanical means, such as are usually employed, necessarily limits what may be said, and I will premise my remarks with the statement that these thoughts may not always incline strictly to the narrow limits of my subject. Certain general principles applicable in the treatment of all forms of fractures are so well understood that it is not considered necessary to discuss them here at length, while certain other ideas not usually discussed at length in the text-books, may receive fuller consideration. Agnew, in his article on "Injuries and Diseases of the Osseous System," says concerning the treatment of fractures, "there is but one indication in the treatment of fractures, and that is to secure the union of the broken bone with the least possible deformity, and this single thought is to animate the surgeon during the entire management of the case." This statement by so great an authority, while unquestionably true, does not seem to contain all the truth, nor indeed did the author seem to so regard the matter, for in another portion of his article, while speaking of fractures he makes use of the following language: "So many complications attend or follow these injuries, such as inflammation, abscesses, ulcers, hemorrhage, tetanus, delirium tremens, necrosis, gangrene, etc., that it is folly to regard this part of professional work as the mere mechanical one. On the contrary, it demands on the part of the surgeon not only the highest degree of anatomical skill and tact, but also a thorough knowledge of the principles of general medicine." These potent utterances of Professor Agnew, made years ago, are, in the main, just as portentous today, when we have so many specialities in medicine and when the fallacy of trying to entirely divorce the surgeon from the physician is receiving such general sanction. It is obviously unwise and incorrect to assume that the former requires only a knowledge of anatomy and a certain manual dexterity, coupled with a genius for mechanics, to the exclusion of that all important equipment, a comprehensive knowledge of the general principles of medicine. Natural bone-setters and osteopaths may

be to the manner born, but the skilful surgeon is of slow, sometimes painfully slow growth.

In the treatment of the particular class of injuries under consideration, as elsewhere throughout the broad field of bone surgery, a factor of prime importance is a careful diagnosis, including a positive knowledge of every detail of the damage done, not only locally to the bony structure and to the soft tissues, but the general state of the patient must be carefully noted with reference to constitutional impressions, especially the state of the circulatory digestive and nervous systems. The excellent rule, now so generally in vogue in railway practice, of obtaining as early as possible a full and correct history of the manner in which the accident occurs, as well as the salient points in the personal and family history of the patient, is frequently of vast importance in reaching correct conclusions as to the diagnosis, treatment and prognosis. Inebriates, syphilitics, drug habitués, diabetics, dyspeptics and those suffering from active or latent tuberculosis, or malignant disease in any form, whether inherited or acquired, demand special attention, and the failure to recognize any cachexia in the management of fracture cases, may result in utter failure and the consequent discomfiture of both patient and surgeon. Conditions of mal-nutrition due to disease of trophic centers which tend to retard or prevent bony union must be appreciated, and efforts directed to overcome such tendencies; and, *per contra*, if a diathesis calculated to provoke an over production of callus be detected, treatment calculated to correct such tendencies should be promptly instituted.

The subjoined case would seem to have a bearing upon the mooted question as to the influence of syphilitic disease in the repair of bones. X. a colored man, about 40 years old, in a fall, received an oblique fracture, about the middle of the upper third of the femur. My colleague, Dr. Baldwin, reduced the fracture and applied a long splint from axilla to heel. At the end of four weeks, it was discovered that union had not taken place. About this time the case came into my hands, when, with the assistance of Drs. Baldwin, Treacy and Bullard, I cut down, freshened the ends of the fragments, wired them with stout silver wire passed through drill holes, placed the limb on a double incline plane, and at the end of five weeks was chagrined to discover non-union. The leg was amputated and subsequently I learned what had been heretofore denied, that the patient was a syphilitic. I have always believed that had the specific factor been known in time a different result might have ensued.

Much can be accomplished in bringing about a proper equilibrium of the needed elements in the repair of bone, by careful attention to dietary measures, as well as the judicious use of proper remedies, and such other agencies as will promote the best general health. Massage, hydrotherapy, electricity, exercise and sunlight, while perhaps not much vaunted by teachers and writers, may each have a proper application in the treatment of fractures, and the careful practitioner will avail himself of these collateral aids whenever the indications are presented. Active and passive motion of involved and contiguous joints should be practiced at the proper time, and if neglected may lead to troublesome complications, or at least delay in the final recovery.

The ambulatory treatment of fractures has been

much discussed during the past few years, and has received the sanction of many distinguished surgeons, both in this country and abroad. Briefly speaking, its chief merit consists in maintaining for the patient, an approximation to the ordinary level of health during the process of repair, by allowing him to take exercise in the open air from the time the permanent dressing is applied. The value of this method of treating fractures is beyond cavil, while the objection which may always preclude its becoming universally popular, lies in the fact that only the few will ever master the technique sufficiently to ensure satisfactory results in the more serious cases occurring in the lower extremities, such as intra-capsular fractures of the thigh, fractures of the pelvis, oblique fractures of the femur, etc. It is, however, entirely practicable, in a large majority of cases of fracture occurring in the shafts of the long bones, whether oblique or otherwise, to give the patients the benefit of easy exercise in the open air by placing them, after the retentive dressing is applied, upon wheel carriages constructed for the purpose. It has been my good fortune during the last four years to witness the decided benefits arising from the adoption of this plan. It is my uniform practice, in all cases where there is not a positive contraindication, to keep patients out of bed most of the time during their waking period, as soon as the permanent dressing has been applied. A matter of great importance is the length of time patients should be confined to bed, or restricted by whatever device is adopted for the retention in place of the broken bone. No positive rules can be given as to when splints should be removed. Repair will progress more rapidly in one case than in another, even where the character of the injury, the surrounding conditions and the plan of treatment adopted are entirely similar, the difference probably being accounted for by a dyscrasia of one or the other. Close observation, with occasional examination of the fracture (without however, needless or meddlesome interference) can alone serve as a safe guide in all cases. Perhaps the commonest mistake in this connection is in not removing dressings soon enough, but, on the other hand, the mistake of too much interference or too early removal of retentive dressings, is fraught with infinitely greater danger, either from non-union, ligamentous union, over production of callus, or in compound fractures, septic infection. Ordinarily, from three to six weeks suffices for fairly firm union.

The occurrence of emboli, either venous or fatty, as a sequence in fractures, while rare, is no longer a matter of doubt and while a condition fraught with such grave results would seem deserving of more than passing notice, it is true that little can be accomplished in the way of prophylaxis, or indeed in giving relief should the thrombus reach the pulmonary circulation and find lodgement. Such a distressing occurrence usually results in death and frequently within a few minutes of the appearance of the first symptoms.

Oblique fractures may occur in any of the bones and constitute a majority of all the cases coming under the observation of the active surgeon. They are more frequent than other forms, because of the structural arrangement of the fibers of bone, these fibers being of varying length and strength, with a converging crescentic shaped arrangement which makes the force of the blow travel in other than a direct line, whether this force be applied in a direction transverse, longitudinal or oblique. This par-

ticular class of injuries does not materially differ from other forms of fracture, either in the manner in which they are inflicted or necessarily in their manner of treatment.

For reasons which were perhaps good a few decades since, but which can not be so regarded from the standpoint of modern knowledge and methods of procedure, oblique fractures, whether simple or compound, were considered as necessarily almost impossible of cure without deformity, and today many of the textbooks assert without qualification that an oblique fracture in the upper half of the femur will, of necessity, result in a shortening of the leg of at least half an inch. It seems deplorable that with all the remarkable advancement surgery has made in recent years, the methods in the treatment of fractures for the most part remain practically stationary. The nomenclature and classification which carries the old dread of compound fractures and the corresponding unconcern about simple fractures has, until quite recently, been left undisturbed.

In the matter of retentive apparatus the greatest ingenuity has been exerted, and certainly with remarkable results. But the question arises, is it not possible that much of this effort has been expended while looking at the subject from a wrong standpoint? In other words, is it not possible that too much stress has been laid upon methods calculated to forcibly overcome muscular action and incomplete replacement of the fragments? In view of our present aids in reaching an exact diagnosis, there would seem to be no reason why in most cases of fracture the broken ends of the bone should not be exactly coapted, and if this is accomplished, there is certainly very little force required to retain them in position until nature has accomplished its work in reuniting them, which result will ensue, ordinarily, without interruption or further complication, providing no constitutional or pathologic antagonism should interfere. Even in cases of compound comminuted fractures with considerable injury to the soft tissues, with the aid of anesthesia, the X-rays and surgically clean methods, why should not each spiculum and fragment be replaced, the torn periosteum carefully attended to, the wound left in an aseptic condition and a satisfactory issue anticipated?

It has been suggested, and I believe the time is approaching when the suggestion will be generally adopted, that in simple fractures where a deformity can not be entirely overcome by complete and exact reduction of the broken bone, not only should an anesthetic always be given, but in a strictly aseptic operation the fracture for the time should be converted into a compound fracture, the necessary fragments removed, any intervening soft tissues disentangled, the ends of bone exactly approximated, if necessary using the saw, forceps or chisel, the wound sealed up and the external dressing applied. We may examine specimens of fractures in any pathologic collection and will find that many of them show evidence that they were not properly set. This will be particularly true of oblique fractures in the shafts of the long bones where the overlapping ends are encircled with enormous quantities of new osseous tissue, the result of nature's effort at repair, though good apposition was not originally secured and maintained.

Is there anyone who, if he should suffer a serious fracture of whatever character and involving a doubtful prognosis, would not prefer to be anesthetized, and

if necessary, leaving to the judgment of the surgeon in attendance to decide, have a clean operation made in order to insure a result which would not handicap him for the balance of his life?

Is there any good reason why a patient suffering from the effects of a severe fracture should be pulled and hauled, with extension and counter extension, and not have the benefits of anesthesia combined, if necessary, with a skilful operation at the hands of a qualified surgeon?

The suggestion made by Senn of wrapping the replaced fragments with chromicized catgut, or in less oblique or transverse fractures, the use of the bone ferrule, is entirely practicable and may be employed even in the most difficult cases, providing satisfactory reduction is accomplished. Nailing, the use of ivory pegs, wiring with steel or silver wire, or suturing with animal ligatures such as strong gut, snell or kangaroo tendon, are orthodox procedures, possessing tested merits, as are also stimulations by rubbing the ends of the fragments together, the use of drills for the same purpose and transfixion.

The use of prepared bone chips in cases where there is great comminution with loss of bony tissue, has not proven satisfactory, excepting in isolated cases. As a rule reproduction of bone is best accomplished through the medium of fragments which still retain some periosteal connection and which have been carefully replaced and retained *in situ*.

I believe that the present generation will see the X-rays and the fluorescent screen in practical everyday use to such an extent that the surgeon will with the aid of these adjuncts, together with the use of progressive aseptic and antiseptic methods, obviate many of the terrors formerly attaching to the practice of bone surgery.

DISCUSSION.

Dr. W. W. GRANT of Denver—The subject of treatment of oblique fractures is a large one and in my remarks I shall refer to certain fractures dealt with by Dr. Mayo and Dr. Cole. I have read the statements made in reference to Dr. Whitman of New York which were published in the *Annals of Surgery*. I see nothing positive to indicate fracture in the cases there reported. The only thing shown was a change in the angle of the neck of the femur; there was no overlapping or other deformity in connection with the cases which were there illustrated. Three or four years ago, in an article which appeared in the *New York Medical Journal*, Dr. Whitman did not call them fractures, but simply a change of angle due to some form of inflammation, particularly known as interstitial osteitis. He states in later articles that he never saw one of them in the case of children. The earliest was three or four weeks after the accident in children and young men. In those cases there is a great difference whether there was a single fracture or not.

In reference to the ambulatory treatment, there are some cases, undoubtedly, in which it would be very useful, but it depends upon each individual as to whether or not it should be applied. In an old debilitated subject, long confinement is bad and interferes with union of bone. If the fracture is transverse treat the case with a fixed dressing. I dislike very much heavy, cumbersome plaster-of-paris dressing, especially when you can make a perfect splint with such nice material as silicated potash, light, and which will hold the parts together just as well. In some of the cases of transverse fracture, ambulatory treatment at any age might be applied; in very oblique fractures I doubt the advisability of the ambulatory treatment unless we are prepared to find more shortening than we desire. In fractures of the upper third of the femur and neck, placing the limb upon an inclined plane is a better position; we will have less shortening and it is more comfortable for the patient. It relaxes the rotator and flexor muscles, therefore it is desirable. In fractures below that, ordinary extension, Buck's extension, is what we desire. Notwithstanding the researches of Dr. Abbé and others, a very unsatisfactory state of affairs exists in reference to certain fractures of the arm, I allude to fractures of the humerus near the articulation. Dr. Bull's

collation is excellent and was made while he was surgeon in one of the New York hospitals, and yet it throws no additional light upon the subject. Dr. Allis maintained that a fracture could be treated with the arm in the extended position. Dr. Bull's flexed position was the one used in the hospitals in New York. In every position where the fracture is low down and slightly oblique we will have overriding of the fragments and some trouble with the arm. I know of no ordinary method in use that will meet all of these cases. It certainly appears if we flex the arm that we produce tension on the triceps, which will pass into the olecranon and pull upward against the lower fragment. If we extend it we have the brachialis and biceps under tension, and therefore I see no great advantage in either extreme position. And with all positions, to maintain the fragments in perfect position will affect the fossa of the olecranon and coronoid process, and it is desirable to have some form of extension in connection with the treatment of such fractures.

In a case that has recently come under my care I have taken three or four pictures with the X-ray to see the position the bone was in, and I defy anyone in examining the arm with the eye and hand to show a particle of malposition; the result is a good one. The X-ray showed the upper fragment overlapping the lower, which was caused in not being able to flex the arm perfectly. The fracture involved part of the fossa of the olecranon and the coronoid process. How to meet those indications and the action of those muscles is a question the future must determine.

I will not say more in reference to fractures of the neck of the femur, except that ligamentous union is still the rule. This will be so, unless we can deviate from the rule, to frequently advise the patient to get up and about. It is absolutely necessary to obtain bony union to confine the patient strictly to bed; the parts should be fixed and the fragments not allowed to move on each other; ligamentous union will be the result. I do not believe we should make a practice of cutting down to determine whether fractures exist or not. If we did this we would have more malpractice suits than from any other procedure. To secure bony union, to fasten the ends together, is a risk the patient should take and not the surgeon. There is no fixed rule of treatment in reference to these fractures. It is safe for the surgeon to maintain that ligamentous union will be the result, and we should remember that a mere change of angle in the neck of the femur is not in itself an evidence of fracture.

Dr. W. L. BUECHNER of Youngstown, Ohio—The most successful treatment for fractures of the lower part of the humerus that I have seen was in Volkmann's clinic in 1886, introduced by his assistant. A splint was gotten up for that purpose, made so that the surgeon could change the angle to any position desired. This treatment has been adopted recently by some of our surgeons in Denver. I have never seen as good results from any other treatment. Massage and passive motion can be made immediately without changing the angle of the limb. I have since treated fifteen or twenty cases by this method and have had no bad results. About two years ago a man was thrown from a horse and fractured the lower part of the humerus. He was treated in this way and now has a perfect arm. A few days afterward a little boy sustained a fracture at the elbow, was similarly treated, and has a perfect arm. I never saw fractures of this kind treated by any other without having more or less ankylosis.

Dr. ARTHUR D. BEVAN of Chicago—I have about three hundred skeletons which have been prepared from my dissecting room and I have carefully studied the fractures in these skeletons. One surprising thing is their frequency. Fractures of the ribs occurred in about 20 per cent. Fractures of the long bones are quite common. The cadavers from which the skeletons were obtained are largely from poor-house and hospital material and would probably represent a very much larger percentage of fractures than would occur in a general community. One thing that will impress you if you examine these skeletons is the fact that in fractures of the long bones hardly a single case occurs in which the bone has been so well adapted that one-half of the diameter of the fragment comes in contact with the other half. Almost all of them do not impinge upon each other, there is a great tendency to overlapping. A great many of the fragments are in a position so that there is no absolute contact between the ends of the fracture. This is important because many fractures must have been fairly well handled. You can demonstrate this in the dissecting room by making fractures experimentally upon a limb fairly well covered with soft tissue in the thigh or in any place in which the bone is not subcutaneous, as, for instance, in the radius at its upper half, in the femur, in the fibula in its upper half. In a fairly well covered leg palpation will not outline even the course it forms.

Another point which presents itself in this work, which I have done experimentally in the dissecting room, is this, the degree of the reduction of a fracture depends upon the muscular contraction. You will find almost as much difficulty in reducing a fracture of the cadaver properly as you will on the living subject, certainly as much as on the living subject under an anesthetic. The difficulty is largely due to the irregular spicula of bone. You have, for instance, a fracture of the tibia. It is not absolutely transverse; it has not a clean, plain surface. If you break the bones apart you will have ragged projections of bone; this bone is hard; the ends of the bones jam against each other and small spicula will prevent reduction of the fragments, a point which we should carefully remember.

Another point which prevents reduction to an absolutely normal position is comminution of the fragments. Experimentally I have made fifty Pott's fractures in the dissecting room, but I now refer to Colles' fracture (about fifty of these), which can be readily made on the cadaver by placing the elbow in a certain position on the table and simply over-extending the arm. A Colles' fracture of any type can be made in this way without any extension. If you carry the force further by putting the weight of the body on the Colles' fracture you can produce any extent of deformity that you desire. In these Colles' fractures the amount of deformity depends almost entirely upon the extent of comminution and the difficulty of restoring the bones to an absolutely normal condition depends upon the fact that a certain portion of the radius has been pulverized. The lower end of the radius presents a thin shell of compact tissue containing cancellated tissue in a Colles' fracture. In many of these experiments I would break up the lower end of the radius into fine pieces, that is, pulverize half an inch of it, some of the fragments being the size of a grain of wheat. In this way we absolutely shortened the radius about half an inch. You will never be able to place the bone in exactly the position it occupied before the injury.

Another point which I have been able to follow clinically and in a few cases of postmortem examinations, is with reference to the difficulty of reducing fractures accurately, and one which we sometimes overlook. I refer to the occurrence of blood clot between the fragments, as the simplest example. Take a fracture of the patella. It occurs with great effusion of blood sometimes in the knee joint, and as long as this effusion exists it is impossible to bring the fragments together. But this same factor plays a very important part in the variety of fractures I have been able to show in some railway injuries. If you place a blood clot between the ends of a broken tibia, you may imagine you can take the bones and restore them to their position without any regard to the blood clot, thinking that it would be readily forced into the tissues. But the blood clot is held in position, is bound down by the soft parts, by the periosteum, in such a position that it very often acts as an immovable substance that you can not remove from the ends of the fragments. On this account, in many cases of fracture, reduction should not be attempted until after absorption of the blood clot, except as a preliminary step. The same thing is observed in fracture of the elbow joint. If the fractured joint is filled with effusion and blood clots you can not reduce the fracture until they are absorbed, and the proper time to reduce the fracture and to put on a dressing is after this has taken place.

I have learned much from my examination of fractures experimentally on cadavers, and have been impressed with this fact, that very few of us ever make postmortem examinations in cases of fractures and become familiar with the conditions as they actually exist. I think much valuable knowledge can be obtained by the experimental study of the pathology of fractures, which I think we have very largely neglected.

Dr. W. J. MAYO of Rochester, Minn.—I will ask the Doctor whether he has any knowledge of cases of non-union in syphilitic subjects, in whom specific treatment has proved curative? The most marked pathologic effect of syphilis is upon the blood vessels, exerted largely upon the intima of the arteries, and while I can find no cases in which this has been a direct cause, from its nature it well might be. Also, will the Doctor state just when he applies a fixed dressing for ambulatory treatment, whether early, as advised by Van Arsdale, getting them about at once, or not?

I have not had the courage to do this, for although it has proved a success in the hands of the German school, at the present time, it would be difficult to justify its use in this country, should the result not be good.

Dr. Grant speaks of Whitman's cases of fracture of the neck of the femur in children as being probably due to a bone disease and not a fracture at all. He evidently believes that Whitman has confused his cases with that trouble which is known as "adolescent bending" of the neck of the femur, seen

at times in childhood. Inasmuch as a number of such cases have been reported in the German literature, and as I have seen a well marked example, I would take issue with Dr. Grant. Whitman's cases invariably followed an injury, which is not necessarily the case in the latter disease. In the adolescent bending the direction of the bend has always been the same. In Whitman's cases this was not true of the deformity. In the adolescent bending it may be double, and in the fractures reported all were single, and lastly, in children, union with true bone might occur, while in the same class of injuries in adults ligamentous union would be expected.

In regard to the work of Allis and Powers, which Dr. Grant does not think of any great value, I would also differ. Allis showed that, treated in the straight position, gunstock deformity was less liable to develop. Dr. Powers was connected with Chamber Street Hospital, New York. Here his opportunities were great. He called attention to the value of the Allis method, but began to gradually angle the arm at the end of a week, an important innovation. Cheever well said that if the fragments of bone in the elbow were at least pushed back out of the joint they would be less liable to prove a mechanical obstacle to flexion. Moore of Rochester, N. Y., for years advocated the frequent variation of the angle to prevent stiffness, which the doctor says is practiced in Germany.

Dr. W. J. GALBRAITH of Omaha.—I believe that fractures of the internal condyle and of the head of the radius are the most serious conditions that confront the surgeon, in the line of fractures. The condition I have described is invariably followed by a greater or less degree of deformity.

Dr. C. B. KIBLER of Corry, Pa.—I assisted Dr. Moore in making two examinations in cases of Colles fracture, one in a lady who died a day or two after the injury was received. She had a double Colles fracture of each arm. The fact was brought out and credit has been largely given to Dr. Moore since then, that in all cases of Colles fractures we have a dislocation of the styloid process of the ulna in addition. It is this dislocation that gives us so much trouble.

Ambulatory treatment of fractures of the lower extremities is no doubt proper and a permanent dressing can be applied shortly after the inflammatory condition has subsided. This holds good not only in fractures of the leg, but in the middle third of the thigh. I have been doing this for some time and have no cause to regret it.

Dr. J. P. LORD of Omaha—I do not believe in an oblique fracture involving perhaps the lower third, or the middle of the tibia, complicated with one or more fractures, possibly of the fibula, it would be proper to put a patient upon his feet before some primary union had taken place, at least. I do not believe in very muscular subjects in an oblique fracture of the clavicle, that the patient should be permitted to be off his back for a few days.

Regarding the open treatment of oblique fractures and the immediate retention of the fragments with chromicized catgut, with wire, with sutures, nails or ferrules, while it may be ideal so far as the adjustment of the fragments is concerned, yet I believe those things have quite a limited application. While it might be a temptation for us to treat fractures in this way, with a view to a perfect mechanical effect, which we might obtain, yet there are possibilities for error, which are going to give the profession trouble if this method is followed out universally. Cases in hospital practice where they are under observation, may be treated in this way, but it would be impracticable for a general practitioner to treat them, in many instances. While it may be entirely practicable to treat an intelligent man anywhere, on his feet with an oblique fracture, yet it might not be so with some harum scarum fellow. Many of the patients whom we treat are like children; give them an inch and they take an ell, so that we can not treat such cases by the ambulatory method with safety. There is no particular advantage in doing this. It certainly requires a high degree of mechanical skill, a great deal of time for which we may never get adequate compensation, and it establishes a precedent. If one man has had a fracture treated this way, is able to move around on his feet, another person will want to have the same treatment, and so I doubt the wisdom of this plan of treatment in a very large proportion of cases.

Dr. HOWARD J. WILLIAMS of Macon, Ga. One thing we must remember in the open method of treating simple fractures is adding disfigurement of the operation in the reduction of the fracture. For instance, I had the case of a man with oblique fracture of the jaw. It was almost impossible to reduce the fracture with a splint. He had lost one molar and the bicusps, but the incisors were sound. I tried to reduce the fracture, and then told him that it was impossible to do so and I would have to cut down and wire the jaw. He very seriously objected, saying that he did not want his face disfigured. If

I had gone ahead, not regarding his wish, and performed the operation and left a scar on the outside the damages would have been greater. He would have claimed that he was disfigured, and that there was pain in the scar. For that reason we should reserve these operations for those cases in which it is absolutely impossible to do otherwise, and operate particularly around the shoulder joint, where in such cases McBurney uses his operation for reducing the head when it is complicated with a dislocation of the fractured head.

I want to ask a question. Does syphilis *per se* interfere with union of bone unless there is gumma or syphilitic disease of the bone? I do not think it does. I believe we can get union of bone in a syphilitic case if there is no disease of the bone itself. If there is gumma we will have non-union in some cases. I have treated fractures in men whom I knew had syphilis and got good union, that is, as good union as we usually get. As to shortening, the question comes up in regard to the regeneration of bone. I believe it is a histologic fact that there is softening of the bone. All tissue contracts. It is unnecessary for us to have shortening; if contraction of the soft tissues takes place the bones come nearer together and we will have some shortening.

Dr. MILTON JAY of Chicago.—There are two points that occur to me. One is the speed with which railway surgeons are likely to try to adjust fractures. I am satisfied that in nine-tenths of the cases of comminuted fractures we attempt to bring the fragments into apposition too early, particularly where the comminution involves the joint. It is simply impossible to have that kind of fracture without more or less effusion. In addition, we may have blood clot. If we attempt to force by fixation those fragments together we will create more trouble than by allowing days to intervene before the application of a permanent dressing. I have seen illustrations of this in the past year. I remember of having a fracture involving the elbow joint, in a boy 10 years old, from falling. The humerus was split, condyles separated and the internal condyle broken off. The arm was put into an ordinary dressing and in two or three days there was swelling, ecchymosis and it was getting black. It looked as though the boy would lose the arm. By taking off the dressing, placing the arm in an easy position and applying antiseptic lotions for a few days the swelling subsided and the bones were found coming together. At the end of two weeks the swelling had all disappeared; I drew the fragments together, circulation had become established, I put on a fixed dressing and the boy has a good arm. The point I wish to make is that in compound or comminuted fractures or in fractures that involve any of the joints, I do not believe it is good surgery to place the fragments in position at once. I would wait until inflammation has disappeared and absorption taken place before attempting to bring the fragments together. The other point I wish to refer to in the treatment of fractures is this: We must pay some attention to the medical treatment of the patient. The constitution of the patient must be looked after. In syphilitics the bones may or may not unite. I have no doubt there are cases on record of syphilis where the bones have united, and there are some where they have not and will not unite. A short time ago I saw a case of fracture of the femur, about four inches below the trochanter. The fragments were adjusted and the limb put up in ordinary splints. Six weeks after the bones fell apart, and even at the end of eight months there was still no union of bone. When I was called to see the patient I found that she had syphilis. I put her upon iodid of potash, commencing with the saturated solution, twenty drops, and kept increasing it until she was taking forty drops a day. She was under this treatment eight weeks, after which I reopened, brought the fragments together and secured union of the bone. I have had three cases of this kind within the last few years and failed to get union when I knew the fragments were placed in apposition. With the constitutional treatment for syphilis the bones do unite.

Dr. J. B. MCGAUGHEY of Winona, Minn.—There is one method of uniting fractures which I have not heard mentioned either in the paper or in the discussion, namely, of uniting the bones by silver wire or screws. What little experience I have had with this method has been exceedingly satisfactory. The wound is kept in a thoroughly aseptic condition, and after a certain time the plates and screws are removed and the wound allowed to heal. I believe this method has been extensively practiced in the Johns Hopkins Hospital.

Dr. FRED. J. HODGES of Anderson, Ind. A friend of mine who does an extensive hospital practice makes use of plaster primarily in these cases, and he puts on a pretty snug dressing immediately after the case come under his care unless there is considerable injury to the soft parts, and he gets excellent results as regards deformity and shortening. His experience

during the last ten years in the treatment of over six hundred fractures, by means of plaster in this way, has been satisfactory and his results equal those obtained by any other method. It is said, and justly so, that each man has his own method, and that method with which he is the most familiar is the one that will give the best results. But certainly the method of securing entire reduction of the deformity and the application of plaster dressings in this man's hands give practically ideal results.

Dr. L. E. LEMEN of Denver. The main point in the treatment of all fractures is to restore the limb to as near the condition as possible that it was in before the fracture occurred. It matters not what measures you adopt if you obtain good results.

Dr. W. L. BUECHNER of Youngstown, Ohio—I would like to hear an expression of opinion from the members of the Academy as to their experience with ununited fractures since we have adopted the antiseptic and aseptic treatment. Professor Volkmann told me that in his large clinic he had more ununited fractures since this was adopted than before, and he was the first man to follow the teachings of Lister on the Continent of Europe, and he ascribes the cause of it to the fact that there is not as much lymph thrown out to unite bone.

Dr. CHARLES K. COLE of Helena, Mont.—Answering the question propounded by Dr. Mayo and Dr. Williams as to the certainty of syphilis interfering with the repair of bone, I think this is about all that can be said in view of our present knowledge, that while syphilis may not *per se* interfere with the union of bone, syphilis or any other condition which interferes with the proper nutrition of the body, or any depraved condition of the system will interfere with the union of bone. To that extent we are warranted in stating that syphilis is a factor in the management of these cases, and we would not be warranted after having recognized syphilis in a given case, in not putting the patient upon the proper antisyphilitic treatment.

Dr. BEVAN spoke of that part of my paper dealing with the solid condition of the ends of the fragments and the rôle it played in the reduction. If we can separate the fragments of an oblique fracture in the shaft of the long bones sufficiently to replace those fragments, the very fact of the unyielding condition of the ends will retain the fragments in place, and I believe that the prime object in the treatment of fractures is to overcome muscular action. I believe it is possible in most cases of fracture of any kind in any bone with proper manipulation, and being deliberate about it, waiting if necessary until swelling has subsided and absorption has taken place, to put the fragments where they belong and a simple device will retain them in position. While I am aware that it is taking an extreme view, I believe the time will come when we will not consider that fractures in the middle or upper third of the femur must necessarily result in shortening.

Dr. McGaughey spoke of a method which was not mentioned in the paper, as did also Drs. Smith and Hodges. But I will say that any device which will keep the fragments in place will answer the purpose, and any scheme which will bring about satisfactory results should be used no matter what it may be.

With reference to Dr. Lord's remarks on the ambulatory treatment, I think the Doctor, in part at least, misunderstood what I intended to say in the paper, because I did not intend to convey the idea that the ambulatory treatment of fractures was an approved method in all cases, or indeed in any instances so far as the general practitioner is concerned. The paper distinctly says that the ambulatory treatment of fractures can not become popular, because only a few master the technique sufficiently to insure satisfactory results in the more difficult cases. I discriminated between the ambulatory treatment of fractures as promulgated a few years ago, and the method of treating a fracture of the tibia without fracture of the fibula, or with fracture of the fibula, in many instances where the dressing can be applied and the patient at once placed upon a carriage or put upon crutches and allowed to walk the wards of the hospital, or to go out and obtain fresh air during the repair of of the bone.

Dr. W. L. SMITH of Streator, Ill.—How many of you have had cases of pneumonia following fracture of the tibia, the patient remaining in bed two or three weeks?

Dr. W. J. GALBRAITH of Omaha—I wish to take issue with some of Dr. Coles' remarks in this particular, the imperative results that he looks for in fractures in securing and maintaining apposition. I do not feel that I would be safe in facing a jury when so eminent a surgeon as Dr. Cole has taken the stand and said that it is easy to secure and maintain apposition, and that we should receive and expect favorable results in all cases. I will ask him as a favor to modify such a statement and explain to us the mechanical and pathologic complications that we meet in fractures and their results.

Dr. COLE—I think Dr. Galbraith misunderstood my remarks. I did not say that we will find in all cases the results will be satisfactory, and that in all cases the fragments could be maintained in position. I qualified what I said about that, and distinctly stated that I realize a prognostication of the statement was rather an extreme view, and one which could not at present be accepted as a fact, and could not dominate us in our work in this connection.

SOCIETY PROCEEDINGS.

Kentucky State Medical Society.

Forty-third Annual Meeting of the State Medical Society, held May 11, 12 and 13, at Maysville, Ky.

The president, Dr. J. M. MATHEWS in the chair.

The address of welcome was delivered by Hon. C. D. NEWELL and was responded to by Dr. JOHN A. LEWIS of Georgetown.

The paper by Dr. ARCH. DIXON of Henderson, on "Pathology of Osteomyelitis," was read by title.

Dr. JAMES B. BULLITT of Louisville read a paper entitled

DIAGNOSIS AND TREATMENT OF OSTEOMYELITIS.

It was defined as an inflammation of medulla of bone, bone itself and its covering. The primary seat may be in the periosteum, chemic irritants and micro-organisms being causes. No specific organism exists, the staphylococcus pyogenes aureus being the most frequent of the pus-producing organisms causing it. It is essentially a disease of childhood, the bones at this time being richly endowed with blood vessels. In adults a local injury generally precedes, at the site of the disease, the modifying of the circulation causing deposition of infection agents. It affects the femur most frequently; males more often than females; primary and secondary disease. Rapid thrombosis, coagulation necrosis, rapid sequestration, are the essential pathologic processes. The course may be very rapid, causing death very soon, from septicemia or pyemia as a rule. A mild degree of osteomyelitis may occur with resolution. A feeling of great exhaustion, with pain, are usual symptoms; also chills and fever and symptoms of typhoid fever. Pain becomes localized and muscular spasm is present, and edema in twenty-four to forty-eight hours should be considered pathognomonic. Purulent synovitis occurs in neighboring joints. Scarlatinal eruption frequently develops. The fulminating form may be complicated by fat embolism from the medulla. Acute rheumatism is frequently mistaken for osteomyelitis; typhoid fever is also suspected from the typhoid state in which these cases fall. The treatment is essentially surgical. Open the medullary canal and remove all infected parts.

Dr. JOHN M. FOSTER of Richmond said his experience was limited to some dozen cases, but one seen early enough for radical treatment to save the limb. He related one case in which osteomyelitis had followed a fall of about ten feet, developing in the ankle. It was not recognized at first and when seen there were two large sacs of pus on the under part of the leg. They were opened, but he found amputation necessary on account of extensive involvement. Amputation was made at the middle third of the thigh, and medullary tissue found in the femur, but a drainage tube in the medullary canal, after curetting, gave a good result. This case was mentioned to show how destructive the disease is, having extended from the ankle to middle of thigh in a short time. The treatment is surgical and should be prompt and thorough. The diagnosis is often difficult.

Dr. W. L. RODMAN of Louisville wished to emphasize that it is frequently not possible to differentiate between osteitis, periostitis and osteomyelitis, they merge so one into another. Those cases of an explosive character are frequently difficult of diagnosis. The age of the patient is often an assistance. Medical treatment avails nothing: prompt and judicious surgery is the only thing. Trephine the medullary canal and drain, upon the same principle as in other cavities of the body. If this done is promptly we will see fewer cases in the chronic state. He would not agree that the femur was most frequently involved, his experience being that it was in the tibia and humerus.

Dr. B. MERRILL RICKETTS of Cincinnati believed that operative procedures were not resorted to often enough. Frequent exploration should be made, two or three trephines in the bone to find out cause of symptoms. He uses the irrigating curette, also Wyeth's method, curetting out the canal, leaving the bone and draining with tube, which is drawn out and cut off from one-fourth to one-half inch each day.

Dr. JAMES B. BULLITT, in closing, stated that the amputa-

tion referred to in the paper, was that done for the condition at the close of the process, leaving a maimed limb. His statement that the femur was more frequently involved was not from individual experience, but was Tillman's, whose practice was where more observations were made than by any other observer.

A paper by Dr. D. S. REYNOLDS of Louisville, entitled "Mental Responsibility," was read by title.

THE RATIONAL THERAPEUTICS OF SOME OF THE ANIMAL EXTRACTS was read by Dr. ALEXANDER BATE of Louisville.

The modern group of animal extracts mentioned were pepsin, pancreatin, ox gall, beef, blood, bone marrow, spermin, nuclein, thyroid, suprarenal, thymus, orchitic, brain, renal, splenic, ovarian, uterine, cardiac and lymphatic extracts. Two classes of extracts were mentioned, those made from structures that are secreting organs, and the non-striated muscle. The use of these extracts can not be limited to isopathy, but when administered upon isopathic principles, as the thyroid in myxedema, etc., they must be continued, just as food must be repeated to relieve recurring hunger. In all cases reported cured the subsequent history of the case has shown that the withdrawal of the medicament has been followed by a recurrence of the disorder, but again controlled by a re-administration.

Dr. R. C. McCHORD of Lebanon read a paper on

THE UTILITY OF THE BLOOD CLOT IN THE TREATMENT OF WOUNDS.

He detailed his experience with Schede's method and considers it a valuable agent, especially in damages to fingers from machinery, with exposed bone to the extent of one-fourth inch, which could be covered with a blood clot.

SYPHILIS; WHENCE DID IT ORIGINATE AND WHERE IS IT NOW?

was by Dr. HENRY PLUMMER of Harrodsburg. He said: No author on syphilis tells us from whence it originated. Genesis and the Psalmist tells us of sins visited upon children, which from the description must have been syphilis. As to "whence did it come?" he was incompetent to answer. "Where is it now?" might be answered, everywhere, from the communion cup to the infant, and in all walks of life." He quoted statistics showing the extent of prostitution in all parts of the world and said that if there were no syphilis there would be no tuberculosis, rachitis, leprosy, lupus, or natural abortions, they all belong to the same family. He ventured the statement that it was his opinion that syphilis was never cured.

Dr. A. G. BLINCOE of Bardstown read a paper entitled "A Contribution to the Study of Eye Strain as a Cause of Nervous Diseases," and a paper by Dr. JAMES M. ANDERS of Philadelphia, entitled "Ether Pneumonia," was read Dr. W. L. RODMAN in the absence of the author.

FIRST DAY—EVENING SESSION.

After a short address of welcome by Dr. JOHN M. BROWN, the annual address was delivered by the president, Dr. JOS. M. MATHEWS of Louisville. In his address he paid a feeling tribute to the memory of a former president of the Society, Dr. Jno. Q. A. Stewart, recently deceased. He then took up, *seriatim*, the following subjects:

1. *State Board of Health.*—He said that when addressing a recent meeting of the New York State Medical Society he had stated that there were no "quacks" in the State of Kentucky, and the remark had provoked great applause, and he further stated that Kentucky was the only State in the Union which has accomplished so much. Attention was called to the fact that the enforcement of the law against quackery now rests with the courts and not with the board as so many seem to think. Any person who knows of a case of violation of the Practice Act should only swear out a warrant and appear before a jury and state the facts, the board being always willing to assist such prosecution. Due credit was given to the Secretary of the Board, Dr. J. N. McCormack, for obtaining the much-needed legislation during the last session of the legislature regarding the "osteopaths," but also to the profession at large.

2. *The relation of the people to the profession.*—He hoped that the day would not be far off when the people could learn to discriminate between the pretender who strews pamphlets at the door and the hard-working and competent physician; to know the difference between jealousy and contempt and not ascribe to the family physician an envy when he is in truth trying to protect them from a fraud; and the minister of the gospel to withhold his pen from endorsing that which would ruin the health and destroy the life of trusting parishoners.

3. *The Rush Monument Fund.*—Attention was called to the resolution passed at the 1884 meeting of the AMERICAN MEDICAL ASSOCIATION, when it was resolved to undertake to erect a statue to Dr. Benjamin Rush in the city of Washington by the

members of the profession in the United States. Mention was made of the splendid result of the call made for subscriptions received at the Philadelphia meeting of the AMERICAN MEDICAL ASSOCIATION, and the pledge made by him as the President of the State Society of Kentucky that "Kentucky would do its duty." He urged upon the members the necessity of getting to work and appointed a committee for the purpose of getting a subscription together.

4. *THE AMERICAN MEDICAL ASSOCIATION.*—A splendid tribute was paid to this society, "the peer of any medical organization in the world." He urged every one that possibly could make the sacrifice of time to attend the meeting in Denver and congratulated the profession of the State of Colorado for their most excellent preparations.

6. *JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.*—He stated that the JOURNAL was equal to any in the world, under the management of its present editor, it having increased its subscription list to more than ten thousand. He urged it upon the members to subscribe for it though not members of the ASSOCIATION.

SECOND DAY—MORNING SESSION.

Concerning the resignation of Dr. W. L. Rodman as a member of the Society, owing to his removal from the city, upon motion of Dr. Steele Bailey, by a rising vote, Dr. Rodman was elected an honorary member.

The question of Transactions and ways and means was, upon vote of the Society, referred to the Publication Committee.

The suggestion of the President looking to a reorganization of the Society was referred to the following committee: H. E. Tuley, J. N. McCormack, J. A. Lewis.

The following committee was appointed to canvass for the Rush Monument Fund: J. H. Litcher, Jno. G. Cecil, H. K. Adamson.

A paper on

PATHOLOGY AND DIAGNOSIS OF DIPHTHERIA

was read by Dr. C. W. AITKEN of Flemingsburg. He said: The true diphtheria bacillus is capable of being grown through several generations, which is not true of non-pathogenic bacteria which resemble it in the mouth. The tendency for it to penetrate tissues is caused by the temperature in this region, which favors its multiplication. Nasal, pharyngeal and faucial mucous membranes are the most usual site. A passive hyperemia is first of macroscopic appearance, rapidly followed by the grayish-white membrane. Diagnosis, differential, which is of practical bedside use, is important. Every child's throat should be examined when he needs any medical attention, as they so infrequently complain of the throat. The nose should be included in this examination, no matter how intractable the child. There are no pathognomonic bedside means of diagnosis, but many helps are present. Diffuse redness of pharynx and high temperature tells of scarlatina, but it is more difficult in follicular tonsillitis; in the latter sudden onset, high temperature during first twenty-four hours, absence of asthenia, pulse rapid and full, absence of glandular swellings, reaching maximum in twenty-four to thirty-six hours, no albumin unless high temperature, membrane superficial and easily wiped off with no bleeding, does not reform, and appears first day, nearly always bilateral. Microscopy is a great help, but both macroscopic and microscopic findings should be taken into consideration. In the method of microscopic technique the 1/12 oil-immersion lens was recommended, Löffler's culture medium and stain giving the best results. Animal inoculation is a final confirmatory test.

Dr. S. G. DABNEY read a paper on

TREATMENT OF DIPHTHERIA.

Prophylaxis, treatment of nasal and pharyngeal diphtheria and laryngeal were considered. The prophylaxis consisted in carrying out Holt's suggestion of quarantine for ten days in suspicious cases and three weeks in true cases. Antiseptic sprays and gargles, with removals of adenoids and enlarged tonsils were prophylactic, and public funerals should be prohibited. Antitoxin as a prophylaxis has shown, in more than fifteen thousand, that only seventy-nine had the disease in three days after exposure, and to these an insufficient dosage had been given. The period of immunity is three weeks. In public institutions antitoxin for prophylaxis should be used, and be used in all very suspicious cases; the earlier the use the better the result. In laryngeal cases the use, even if late, is of great efficiency when assisted by intubation. Any practitioner who has read the American Pediatric Society's report and fails to use antitoxin should not be allowed to care for diphtheria. Statistics were quoted showing the result of antitoxin both in hospital and private practice and its use urged most emphatically. A concentrated dose is recommended,

600 units in mild case of child 2 years old; in severe, 1000 units. Laryngeal cases should be considered severe. The effect on the membrane is noticed in twenty-four hours. Hypodermic injection should be used, in thigh, back or abdomen. In rare cases pain in the joints or eruption may be caused, but nephritis is certainly diminished by the use of antitoxin. Stimulation is next in importance, whisky and strychnia of most value, giving one ounce of the former in twenty-four hours to a child 4 years old, beginning when indicated by pulse and depression. Muriated tincture of iron should be given in streptococcus infection. Local treatment should be cleanliness rather than antiseptics, using no force. Peroxid of hydrogen was not recommended. Practice in intubation upon larynx of dog was recommended to those unfamiliar with technique.

Dr. G. G. THORNTON of Gravel Switch read a paper on "Membranous Croup and Intubation, with Report of Cases." He took the position that membranous croup and diphtheria were two distinct diseases, from his experience in seeing cases which had had no exposure and others who were exposed and not stricken with the disease. Antitoxin is not to be considered in membranous croup as it is only specific in diphtheria. Tracheotomy and intubation are only to be considered, the latter in preference to tracheotomy.

Dr. J. A. STUCKY of Lexington stated that diphtheria was practically a stranger in Lexington, and he believed there were no more than fifty cases in Lexington in the last ten years. He believed there was a difference between diphtheria and membranous croup; the former a blood poison, a treacherous disease, contagious and infectious, leaves sequelae, while in pseudo-diphtheria or membranous croup, the opposite is the condition. An early diagnosis is necessary; cleanliness and sun are both valuable as a prophylactic. He doubts the efficacy of treating the throats of other members of the family exposed, and should leave the filter of the nose undisturbed. There is some benefit from the use of protonuclein.

Dr. THOS. J. SHOEMAKER of Morganfield stated that diphtheria was rare in his neighborhood, he having seen but a few cases in thirty-three years practice. It is a filth and constitutional disease.

Dr. J. H. LETCHER of Henderson emphasized the importance of making an early diagnosis, and we are on the safe side if we suppose it is diphtheria; if recognized early enough we get to work early. His opinion was that more cases occur than are diagnosed, as he alone has operated on twenty-six cases of laryngeal diphtheria in his county since 1886, and he was sure that more cases occurred.

Dr. F. L. LAPSLEY of Paris believed that diagnosis by means of microscopic examination was difficult, as the pseudo-bacillus resembled the true bacillus. He considered ice applications to the throat a valuable remedy, soothing and allaying lymphatic engorgement. Examine cases early. It is criminal to fail to use antitoxin in all cases.

Dr. AIKEN, in reply, stated that only by animal inoculation could the differential diagnosis be made between the true and false bacilli. Croup and diphtheria are the same disease. The physical structure of the larynx and pharynx is not the same; in the larynx they die from obstruction, in the pharynx from sepsis. It is a local disease from the beginning. He does not believe in the use of steam as this heat and moisture aids in the growth of the bacillus.

Dr. DABNEY stated that his personal experience showed the efficacy of steam in aiding separation of the membrane. Those cases in which swelling of the neck occurs are cases of streptococcus infection. Diphtheria is certainly more common in cities; there should not be any question of diagnosis when a laryngeal case occurs after a follicular or membranous condition in the throat. The absence of albumin and failure of occurrence of post-diphtheritic paralysis is not against the diagnosis of diphtheria. Antitoxin has certainly caused us to see less of these cases of complication than formerly.

A paper entitled "The Influence of Age, Race and Sex in Surgical Diseases," was read by Dr. W. L. RODMAN of Louisville.

Dr. T. C. EVANS of Louisville read a paper entitled

DEFLECTIONS OF THE NASAL SEPTUM.

Among the deformities mentioned, due to this trouble, were deformity of the nose, distortion of the face, contraction of the alveolar arch and dental irregularities. The complications and sequelae are mouth-breathing, disturbance of speech, chronic deafness, hay-fever, frontal headache, hypersecretion of the nasal cavity, defective drainage, diseases of the accessory sinuses, pharyngitis and laryngitis, asthma. The operation described is practically that of Dr. J. Morris Asch. A general anesthetic is recommended and, as the hemorrhage is

usually profuse, precautions should be taken as to the position of the head. The instruments necessary are Asch's septal scissors, Adams' septal forceps, two vulcanite tubes and a probe-pointed septal knife. Digital exploration of the stenosed side is first done, and if adhesions are present they are dissected up. The first incision is made through the septum in the line of the greatest convexity and parallel with the floor of the nose, and a second incision at right angles to the first, and intersecting it near its center. These incisions are extended to the limit of the cartilaginous septum, which divides the septum into four imperfect, irregular and unequal triangles. An Adams forcep is now introduced, one blade in either nostril, the triangular fragments caught separately and twisted on its base to loosen its articulation and destroy its resiliency. The thoroughness with which this is done will insure the result. After irrigation of the nasal cavities the tubes are introduced; hemorrhage ceases at once. Irrigation should be done every few hours at first, then every two days. After the first week the patient can do this himself. The results of this operation are most excellent.

Dr. J. A. STUCKY of Lexington has not been very enthusiastic over the Asch operation for some time. In the majority of cases it is safer to use a beak and bayonet-pointed knife than scissors which injure the inferior turbinate oftener when there is marked stenoses. The second incision must be made by the knife in any case. The Asch tube has too large external openings and too small internal openings. When under an anesthetic, with much bleeding, you can push the Asch tube through the wrong place into the middle meatus, and may fracture a turbinated bone. He uses a longer and narrower tube. Cocain should be used very cautiously, never alone, but combine 1 per cent. resorcin and the toxic effects are lessened.

Dr. S. G. DABNEY of Louisville was skeptic as to epilepsy caused by nasal deflections, and said that the Asch operation is better in older patients, first making incision before the anesthetic is given, the use of Adams' forceps requiring general anesthesia at later time. The nasal septum is very tolerant of work on it. The bistoury makes much more accurate incisions. The Asch tube is open to many criticisms. Side openings are not necessary. Never use cocain spray. He applies on a swab of cotton directly over the part.

Dr. EVANS, in closing, stated that he rarely used cocain in spray, except when first cleansing tube after operation. The scissors is a valuable instrument for making the first incision, enlarging with a knife.

AN OBSTETRIC OUTFIT.

Dr. HENRY E. TULEY of Louisville exhibited an obstetric outfit, which he had designed, looking to the comfort of the patient, her safety and the convenience of accoucheur and nurse. He called attention to the fact that other outfits which had been suggested formerly were either too expensive or not selected with the needs of the patient or physician especially considered. The following articles are enclosed in a hermetically sealed box, after thorough sterilization, and instructions are printed on it that it is not to be opened except by the nurse or physician: half dozen lochia pads (designed after those used at the Sloane Maternity Hospital); obstetrical bed; five yards of plain sterilized gauze; half pound of absorbent cotton; two dozen safety pins, two sizes; fountain syringe; nail brush; nail file; antiseptic soap; antiseptic tablets (bichlorid); tube of white vaselin; plain vaselin; one ounce of Squibb's chloroform; six ounces of saturated solution of boric acid; sterilized tape for cord; cord dressing (made of balsam Peru, m. xx, ol. ricini 0.5 ounce, which causes the cord to separate more quickly, is easier to handle, and minimizes the chance for infection); Crede eye solution; pipette and fl. ext. ergot.

Dr. FRANK L. LAPSLEY of Paris—There are useful articles in the outfit, but the country practitioner can not get this as a rule. In his outfit he carries also chloroform and ergotole, to be used hypodermically. Never use silk cord. Does not change dressing at all.

Dr. F. F. BRYAN of Georgetown read a paper on "Extra-uterine Pregnancy."

Dr. L. C. WADSWORTH of Newport read a paper on

THE MIDWIFE AND MIDWIFERY.

He stated that while nature does in many cases, the majority care for cases of labor, interference is often indicated and the intelligent interference or assistance makes midwifery a science. The midwife attends the labor for a small fee, and returns for nine days, washing the patient and doing all the household work. In this State midwives are specially exempt from the State laws governing the practice of midwifery. The ordinance governing midwifery in Newport was read—a very comprehensive one.

Dr. EDWIN RICKETTS of Cincinnati, had recently seen a family in which there were six cases of delivery and six cases of sepsis. He wished to go on record as believing the midwife should go. They are the cause of more puerperal peritonitis than any other being, and the physician covers her mistakes. They cause many troubles, one of the severest a complete puerperia.

Dr. J. H. LETCHER of Henderson, emphasized the importance of early diagnosis by the practitioner and proper surgical relief. He reported a case of full term abnormal pregnancy with a living child, which is now four years old. The mother died on the fourth day.

Prof. REAMY of Cincinnati, had had one such case of abdominal pregnancy. The midwife should not be charged with every case of sepsis, puerperia and other complications. Abroad the midwives are recognized and encouraged by the profession. Restriction should be placed on these women until they are prepared thoroughly. If they are trained in aseptic principles, in anatomy and physiology of parts, they should be allowed to practice in proper quarters.

Dr. JAS. BULLITT of Louisville, believed Dr. Reamy's view the proper one. The midwives we have here should go, but the good midwives should be welcomed. Many women prefer to be served by women if they are capable. Midwives should be educated to recognize abnormalities and to care for normal cases.

Dr. GEORGE E. DAVIS of Lawrenceburg, read a paper entitled "The Physiology of the Liver and the Role it Plays in Digestion and Nutrition."

Dr. B. W. SMOCK of Louisville, read a paper entitled

VACCINATION.

He made a plea for more general vaccination and revaccination. Investigation showing that a larger number of children are going every year unvaccinated, as well as adults. This must be caused by no epidemic having been brought to general notice. Vaccination should be done in infancy, at puberty and mature age. Immunity of doctors and nurses in smallpox hospitals is the best evidence of its efficacy. No such thing as constitutional insusceptibility to vaccination exists; it is simply a confession on the part of the vaccinator that he has not found why he has not succeeded.

Dr. C. C. LEWIS of Stamping Ground—When does vaccination run out? is a question frequently asked every doctor. He can not see why there is a necessity for more than one vaccination during life.

Dr. MEREDITH of Bergin, said that as to the question of immunity for life, on his own person it has taken twice; at least every seven years should be the rule.

Dr. J. N. McCORMACK of Bowling Green, believed if Dr. Lewis had seen more epidemics of smallpox he would be cured of his idea of life immunity. Statistics show that the percentage of varioloid depends largely on the number of scars of vaccination. He has often had the second vaccination take. If cases exposed are vaccinated before the pustular stage of the first case and removed they will not contract smallpox as a rule. Vaccination in contra-distinction to vaccination, the saturation of system with vaccinia virus is recommended especially for physicians. Vaccination is very frequently improperly done. There should be thorough regard had for aseptics and antisepsis if need be, and if this be done much unnecessary soreness of the arm and inflammatory reaction would be done away with.

Dr. ISAAC A. SHERLEY of Winchester, read a paper entitled

A CASE OF HEMATOMA OF THE VULVA FOLLOWING NORMAL LABOR; OPERATION; RECOVERY.

He said: Hematoma occurs but once in 1600 deliveries, according to one author and in 14,000 according to another. Varicose veins, a large head, great expulsive pains and efforts, are given by most as causes. If occurring during labor immediate interference may be necessary. The case reported was a primipara, 19 years of age, the labor a dry one four hours long. Twenty minutes after delivery he found a slight prolapse of uterus and a tumor of the left labium. Two days later pulse 130, temperature 104 degrees; gangrenous odor from pent-up lochia. The clot was turned out the cavity, packed and thorough drainage obtained without hemorrhage.

Dr. J. B. BULLITT of Louisville, related a similar case, the tumor being the size of a goose egg. The incision was made and drainage done with recovery. These cases should be relieved by operation, that much blood being unable to be absorbed.

THIRD DAY—MORNING SESSION.

The Nominating Committee made the following report: President, David Barrow of Lexington; first vice president, H. K. Adamson of Maysville; second vice president, Jas. B. Bullitt

of Louisville; treasurer, C. W. Aitken of Flemingsburg; secretary, Steele Bailey of Stanford; librarian, B. W. Smock of Louisville; Chairman Committee of Arrangements, Jno. G. Cecil of Louisville.

Board of Censors: B. L. Coleman of Lexington; L. L. Robertson of Middlesboro; J. H. Shoemaker of Morganfield; T. B. Greenly of Meadow Lawn; W. S. Simmons of Smiths Grove; N. H. McNew of Carlisle.

Chicago Academy of Medicine.

Regular Meeting, March 18, 1898.

JAMES G. KIERNAN, M.D., in the Chair.

SYLLABUS OF ACADEMY DISCUSSION ON TUBERCULOSIS.

1. Dr. C. Fisch, Orrotherapy.
2. Dr. H. M. Thomas, Tuberculosis of Throat.
3. Dr. E. S. Talbot, Oral Cavity in Tuberculosis.
4. Dr. Halstead, Abdominal Tuberculosis.
5. Dr. Paddock, Effect of Pregnancy on Tuberculosis.
6. Dr. Babcock, Remarks on Tuberculosis.
7. Dr. Wood, Tuberculosis of Ocular Structures.
8. Dr. Brower, Tubercular Meningitis.
9. Dr. Alexander, Mental Phases of Tuberculosis.
10. Dr. Ferguson, Tuberculosis of Breasts.
11. Dr. Ridlon, Tuberculosis of Joints.
12. Dr. Engelmann, Pediatric Aspect of Tuberculosis.
13. Dr. Waugh, Climatology in Treatment of Pulmonary Tuberculosis.
14. Dr. Baum, Tuberculosis of Skin and Genito-Urinary Organs.

The subject for discussion was

TUBERCULOSIS,

which was considered from various specialistic standpoints.

Dr. C. FISCH of St. Louis, Mo., spoke (by invitation) on

ORROTHERAPY.

He said: In our hitherto essentially empiric conceptions of serum therapy, the last two or three months have wrought a decided change: a galaxy of investigations published by Ehrlich, Wasserman and Behring have shown a path which certainly will lead to a complete theoretic grasping and understanding of the problem. Already our horizon has widened and many barriers have been removed; the mystic element so long surrounding this form of isopathic therapy fades away. On the other hand, a number of clumsily mechanical and materialistic explanations have received their death-blow.

What is antitoxin, what are antibodies? Ehrlich's answer is plain and plausible: what is more, it has found experimental affirmation in an irrefutable way. When I kill a guinea-pig with a fatal dose of tetanus toxin, I find at the postmortem experimentation considerable quantities of toxin in all of the organs of the animal except in the central nervous system. When, on the other hand, I kill a healthy guinea-pig, its brain and its spinal cord made up in a fine emulsion and injected into other animals, will protect them against, and even cure them from, tetanus poisoning. None of the other organs will do that.

Every animal body, says Ehrlich, contains certain complexes of cells which have a maximal affinity to certain bacterial, or other toxins (the cells of the central nervous system, for instance, to the tetanus toxin). Of each protoplasmic unity of these cells, definite side or lateral groups are integral parts, which combine with the toxin molecules: this binding of the toxins by the lateral molecular groups is what we call the poisoning of the cells, leading, if all of the specific groups are involved, finally, to the cells' death. If only some of them are "anchored," as Ehrlich puts it, the cell loses, for the time being, its functional activity, until regeneration or new formation of the side groups has taken place.

Now, it is a biologic law that every regeneration implies a certain overproduction; a surplus of specific side groups is therefore produced which are by and by detached and discharged into the blood plasma. They form or are the antitoxin, and it will be easily seen that the whole process needs only to be repeated often and intensely enough, to insure the presence of large quantities of antitoxins in the blood. They protect the organism by binding the toxin before it can reach the antitoxin-producing cells, that is, those cells which are susceptible to its action. By transferring them from one organism to the other their action, too, is transferred.

How is this ingenious theory borne out by our observations on the course of tuberculous infection and its isopathic treatment? There is absolutely not the slightest doubt that this infection goes along with a slow insidious intoxication of the

tissue cells, caused by the toxins of Koch's bacillus and directly, as well as indirectly, leading to necrosis and destruction. It does not matter which one of the several toxic bodies that we are able to isolate from tubercle cultures is the most active and deleterious; in human, as well as animal tuberculosis, we have always to deal with their combined action, and the question, therefore, simply is, can tuberculosis (in animal experiments) be cured by active and passive immunization, and what changes do eventually go along with this process in the animal organism?

Behring reports that it is a comparatively easy thing to cure tuberculous cows by treating them with very active tuberculous toxins. You all know that Koch cured guinea-pigs and that the same has been done by Kitasato, Spengler, Babes and others.

I want to say a few words about two sets of guinea-pigs that I have had under observation now for nine months in my laboratory, and one of which was inoculated with tuberculosis ten months ago. This latter set, consisting of four animals, was cured from its tuberculosis by injections of increasing doses of a tubercle toxin, the preparation of which I have described elsewhere. After six months' continuous treatment the blood serum of these animals attained the property of, in small doses, preventing the tuberculin reaction in diseased guinea-pigs, and to protect healthy animals against fatal doses. The other set (three animals) was not inoculated, but simply treated with the toxin in the same way; their blood, too, protects other pigs, the dose necessary being a little larger. Behring's results with his cows point to the same facts. What does this teach? In the first place, that the serum has acquired antitoxic properties; in the second place, that such a change is brought about easier in infected animals than in healthy ones. The cure of the infected animals is evidently due to the antitoxin which was produced in the course of the treatment; it counteracted or neutralized the toxins in a measure as they were produced by the bacilli, thus "depriving them of their greatest terror," and allowing the organism to succeed in the elimination of the innocuous bacilli themselves.

The production of antitoxin by means of toxin injections in healthy animals appears to us in an altogether new light. We now know that it is ridiculous and nonsensical to look around for animals that are immune against tuberculosis in order to find fit subjects for the injections. An animal absolutely immune against one disease can in no way produce a specific antitoxin, since its immunity would involve the absolute absence of the specific protoplasmic side groups, it can not be poisoned with the toxin in question and can therefore not produce superfluous antitoxic groups. The fact that horses are very fit for the production of tubercle antitoxin is not at all due to their immunity against tuberculosis, but to the circumstance that in them the disease usually takes a very slow and chronic course. Best results in them are obtained when in the beginning of treatment moderately virulent living bacilli are injected so as to set up an artificial infection. The antitoxic potency of their blood can reach a high degree.

As to the site of origin of the antitoxic bodies in tuberculosis, we are as yet absolutely groping in the dark. I hear that Behring and his disciples are busy investigating in this direction, but it may be surmised that the result will not be so plain and unmistakable as was the case with the tetanus antitoxin. It may be that certain lymphatic elements, which are distributed all over the body, will bid fair to play this part.

There can be no doubt that in self-limited diseases like, for instance, lobar pneumonia, the crisis sets in as soon as the amount of antitoxins eliminated from the blood is sufficiently large to neutralize any fresh amount of toxin produced by the pneumococci. The reason why such a self-limitation does not occur always and, indeed, in most infectious cases is missing altogether, is to be looked for in the assumption that in these cases the cell intoxication is so severe that cell death ensues, and regeneration of antibodies is prevented. This, as well as another reason, obtains for tuberculosis; mostly either the intoxicated cells die immediately, or the intoxication is so slow that although a slight over-production of antitoxin takes place, no discharge into the circulation occurs. Thus it is that only in the diseased tissues do we find a slight surplus of antitoxin, as shown by the reactive susceptibility for tuberculin.

Contradictory as it seems at first glance, it will be understood now how Ehrlich's hypothesis enables us to explain the cure of a disease by introduction of a surplus amount of toxin in addition to the amount continuously produced by the microorganisms, causing a slow and insidious disease like tuberculosis. It is clear that this latter amount is not sufficient in quantity to stimulate a copious antitoxin production: the toxin irritation is too slight, it needs the exacerbation by the poison artificially introduced to bring about a larger antitoxic elimination. In this way active immunity against tuberculosis is obtained.

From these desultory remarks, one point will have become evident, that is, that active immunization can not be achieved without, to a certain degree, endangering life. That it can be achieved is proved satisfactorily; that in other cases passive antitoxin-protection and cure will be preferable are just as certain: the prospects that for both ways reliable means and procedures will be found, are very bright just now.

These thoughts I can not better express than with the following words of Behring: "There is always some danger connected in conforming in practice to the claims of isopathic therapy. This danger becomes particularly great in cases where there exists an abnormally high irritability, finding its expression especially in a high body temperature. I trust that particularly those patients with febrile tuberculosis will be benefited most, after we have got possession of a tuberculosis antitoxin sufficiently strong for practical purposes; an antitoxin which conveys to the blood poison-binding substances, without the interference of a previous isopathic tissue-irritation."

TUBERCULOSIS OF THE THROAT.

Dr. HOMER M. THOMAS.—Among the many diseases which involve the larynx that of tuberculosis is the most frequent. It may be mistaken for carcinoma, syphilis, or general catarrhal inflammation. There usually is associated a tuberculosis of the lungs or other organs. This may have pre-existed and the larynx be the last organ to become involved.

Pathology.—Pathologically, the disease is due to the tubercle bacilli. Under a laryngoscopic inspection we observe in a general way, anemia, congestion, tumefaction, erosion and ulceration, with their attendant pathologic changes. Acute tuberculosis of the larynx occurs as a part of acute tuberculous sore throat. It is a condition of acute miliary tuberculosis of the larynx, pharynx, in which the process of ulceration is very rapid and a fatal termination ensues within a short time. Secondary tuberculosis of the larynx may occur from the ejection of sputa from the lower air passages. In most cases infiltration takes place through the lymph channels. Coagulation of the mucous membrane usually marks the first stage of the acute form, while anemia of the mucous membrane is characteristic of the chronic and more frequent type. Acute tuberculosis of the larynx usually sets in after the pulmonary lesions have begun to soften. Acute catarrhal laryngitis, lasting two or three weeks, is succeeded by chronic laryngitis. The characteristic feature resulting from these two forms later on is succeeded by isolated or multiple superficial erosions on the laryngeal surface of the epiglottis and contiguous portions of the laryngeal mucous membrane. Then localized tumefactions in the epiglottis and the arytenoidal extremities of the arytenoid-epiglottic folds. Microscopic inspection of these tumefactions when in an advanced stage, will usually reveal marked infiltration of small lymphoid cells in mucosa and submucosa, nearly down to the glandular layer, and often masses of tubercle nodules, or groups of miliary tubercle, many of which are undergoing caseation.

When the epithelium over these tumefactions becomes loosened, hemorrhagic tuberculous ulcers are seen. The ulcerations continue to deepen and may extend to the limits of cell infiltration and thus reach the perichondrium where they stop, as this structure seems able to resist direct tubercularization. Local suppurative centers of inflammation often exist near ulcerative processes, and when they reach the perichondrium it becomes involved and the cartilage is exposed. The cartilage may undergo necrosis and caries and become destroyed. Secondary tuberculosis of the larynx seldom gives a history of causation from atmospheric exposure. Its onset is insidious and there is marked local anemia of the laryngeal mucous membrane. In some cases the most marked evidences are principally in the vocal bands. The posterior surfaces may become so swollen as to partially occlude the caliber of the larynx to such an extent as to require tracheotomy to prevent suffocation. Perichondritis and chondritis occur in the later stages of long chronic cases. This inflammation may involve one or both surfaces and ultimately lead to structural disintegration.

Etiology.—A constitutional tendency to catarrhal inflammation of the mucous membrane of the air passages is probably the chief cause of tuberculosis of the larynx. Inherited susceptibility appears to have a more marked influence than acquired sources of the disease. No age is exempt. The period between 20 and 30 years is the most frequent. Men more frequently are affected than women. It is not frequent in advanced life. Exposure to inclement weather when insufficiently clothed, and a lowered vital resistance, are a common cause in inducing laryngeal tuberculosis.

Symptomatology.—Dysphonia, cough, dyspnea, pain, sensation as of a foreign body in the throat, are usually present.

Probably the first subjective symptom is dysphonia. The impairment of the voice will be proportionate to the character and location of the tubercular infection. When nervous or due to defective nutrition, the larynx will have an anemic appearance, sometimes due to mechanical causes, as pressure on the nerve supply of hypertrophied laryngeal, tracheal or bronchial glands, or too close approximation of the vocal bands. Dysphonia may progress to complete aphonia, due to thickening of the vocal bands, ventricular bands, or aryteno epiglottic folds posteriorly; morbid growths between the bands or ulceration. With a subsidence of these conditions the voice will be improved, although the constitutional state may be active and the patient be worse. When tubercular ulceration is on the posterior wall of the larynx, pain in swallowing is intense. With ulceration in the pharyngo-epiglottic fold, we may have pain extending to the pharynx and ears. Dyspnea, as a result of laryngeal lesions, only occurs when the constitutional condition is far advanced. Cough is generally present in all cases of laryngeal tuberculosis. At first it is dry, hacking, laryngeal, and may be due to endo laryngeal irritations. Expectoration is slight, except when the pulmonary involvement is advanced.

Diagnosis.—A primary laryngeal tuberculosis must be made by positive exclusion of tuberculosis in the lungs or other organs. Secondly, it may manifest itself in the tongue, uvula, palate or pharynx. Acute pain in deglutition is strong presumptive evidence of tuberculosis, markedly increased in the advanced stage. Involvement of the uvula is indicated by its change into a semi-translucent club-shaped structure, quite different from that due to edema. Quite a proportion of cases of tuberculosis begin in a subacute catarrh of the mucous membrane. In its inception this catarrh is not diagnostic. When associated with it, is a lowered vital resistance, hereditary tendencies, resistance to therapeutic measures, and the catarrhal condition gradually assuming a chronic form, we have strong evidence that it depends upon constitutional rather than local causes. As before stated, the diagnosis is chiefly upon the pathognomonic pallor, pyriform tumefactions of the posterior parts of the aryteno epiglottic fold, circumscribed tumefactions in the meso-arytenoid fold, the horseshoe epiglottis, multiple erosions, ulcerations and other minor changes.

Prognosis.—The prognosis is unfavorable. In exceptional cases there is recovery; the majority die. Acute tubercular infection of the larynx is usually fatal in from six weeks to six months. In the reported cases of cure there is always a suspicion of inaccurate diagnosis, since the disease bears a close resemblance to acutelatent and tertiary syphilis. The chronic varieties of laryngeal tuberculosis are usually associated with slow developing pulmonary tuberculosis, which has its inception in localized pneumonias. In these cases the larynx is secondarily involved after the lungs are much softened. By degrees the structures constituting the borders and anterior portion of the larynx lose their distinctive outline and become tumid, and circumscribed tumefactions arise at different portions, supplied by lymphoid cells. Improvement of the voice is not necessarily an indication for hope of diminished or controlled constitutional invasion, unless verified by laryngoscopic evidences of cure. It is rare to have tubercular ulcers heal. The exception to this statement arises when, as a result of topical applications, cicatrization occurs. For a time healthy granulations may form on the base of an ulcer, but usually fresh tuberculous infiltration causes the newly formed tissue to break down. There is a marked discrepancy in statistics as to the proportion of patients with pulmonary tuberculosis which have tuberculosis of the larynx. The character of one's practice, whether hospital or private, has much to do with this. A fair estimate would be about 10 to 15 per cent.

Treatment.—Constitutional and local measures are indicated. As the question of constitutional measures will be exhaustively considered in the subject of tuberculosis as a whole, I will confine my remarks to the local measures indicated for control of the laryngeal condition. Treatment of the local lesions varies with their character, position, extent, accessibility to topical application, and influence on deglutition and respiration. Circumscribed thickenings with a non-broken surface may be treated with creasoted iodine in glycerin or menthol in solution with olive-oil. An ulcerated larynx can be relieved with an insufflation of iodoform in solution with sulphuric ether. Laryngeal secretions should be removed by direct application of alkaline sprays. When tuberculous ulcerations are on the surface, lactic acid well rubbed in, with a 20 to 40 per cent. strength is valuable. When the resultant eschar falls, repeat the process until cicatrization is established. Where the mucous membrane is not broken, lactic acid is negative. Twenty per cent. solutions of menthol injected into the larynx, in combination with olive oil, is efficacious. Cough, due to ulceration, may be mitigated by insufflations of mor-

phin, in one sixteenth to one-half grain strength. Submucous injections, 3 per cent., hydrocholate cocain for pain; orthoform is a valuable analgesic. Painful deglutition can sometimes be relieved by having the patient lie on his stomach, with head and arms over the bed, the feet being higher than the body. In this position, water and nourishment can be siphoned through a tube reaching from a receptacle held below the mouth. Much temporary relief can be afforded by the inhalation of vaporized antiseptic oils, which, being carried directly to the abraded surfaces, are deposited well over them, and through absorption and mechanical protection greatly allay many of the distressing symptoms attendant upon laryngeal tuberculosis.

THE ORAL CAVITY IN ITS RELATION TO TUBERCULOSIS.

Dr. EUGENE S. TALBOT—Very little can be said in regard to tuberculosis in relation to the jaws and teeth. Tuberculosis does act directly upon the teeth in reducing vitality, and thus causing decay to take place more rapidly. The treatment of such cases, however, is not very successful from the fact that the patient's vitality is so very much reduced, and death usually ensues very soon after rapid decay, and all that can be done is to relieve pain and make the patient as comfortable as possible so far as exposed pulps are concerned.

There is an interesting feature in regard to the indirect effect of tuberculosis upon the jaws and teeth. Children who are born of tuberculous parents almost invariably have an arrest of development of the jaws and frequently, I may say almost invariably, certain of the teeth do not develop. When arrest of the jaws takes place, we have irregularities of the teeth. Nature tries to harmonize the development of the teeth with the arrested jaw by doing away with the wisdom teeth and the lateral incisors, thus giving more room for the teeth to come into place. To give you some idea of the difference in the size of the jaws of children born of tuberculous parents, and those of normal parents, I can only say that the jaws of healthy children should measure two inches to two and one fourth inches in diameter. In children who are born of tuberculous parents the jaws are frequently one inch in diameter, showing a difference of an inch to an inch and a quarter in the lateral diameter. These measurements are very important to the patient as well as to the dentist, because mechanical appliances have to be made in order to correct these irregularities. In such children I have found 45 per cent. of the third molars and 14 per cent. of the lateral incisors wanting.

ABDOMINAL TUBERCULOSIS.

Dr. A. E. HALSTEAD—Abdominal surgery during the last ten years has so greatly enlarged our knowledge of tubercular peritonitis that we no longer regard it as a rare pathologic condition, but one which we frequently encounter and seldom recognize before the abdomen is opened.

The way of entrance of the tubercle bacillus into the peritoneal cavity is often hard to determine. In some cases post-mortem examination shows the peritoneum to be the only organ involved, from which we must consider that the infection is occasionally carried through the blood. In many cases the infection can be traced to a tubercular ulcer of the intestine where the bacilli either pass directly through the intestinal wall or first involve the mesenteric glands, from which infection subsequently spreads to the peritoneum. In these cases the primary intestinal lesion may be very minute and might easily escape notice on post-mortem examination. In children infection of the mesenteric glands with the tubercle bacillus frequently follows attacks of acute enteritis.

Burdon-Sanderson, Sturgis and Carr (cited by Abbé, *Med. News*, 1896), in order to determine the origin of tuberculosis in children, reviewed the findings in several hundred autopsies, and concluded that about one-third died of some form of tuberculosis. Out of 120 autopsies, in two-thirds the thoracic glands were shown to be the point of entrance, while the mesenterics were primarily affected in one sixth. In 107 post-mortems, where death had resulted from peritoneal tuberculosis, Phillips (*Centr. f. Klin. Chir.*, 1890) found the intestine to be the seat of tuberculous disease in eighty, or 74 per cent. of all the cases. In forty-four cases infection of the peritoneum was directly the result of disease of the mesenteric or retroperitoneal glands.

The female genital organs, especially the tubes, are frequently the starting point of the disease. That infection may reach the abdominal cavity through the tubes even in children is shown by the case of Vierordt where, in a girl of six and one-half years, tubercular peritonitis was preceded by a purulent vaginal discharge in which tubercle bacilli had been demonstrated. The relative frequency of infection from the tubes is still a subject of dispute. The proportion given by various writers differs greatly. Taking all available statistics, the

cases in which the tubes are involved comprise about 25 to 30 per cent. of the females affected. It must be remembered, however, that the disease of the tubes is secondary to peritoneal tuberculosis in some cases instead of being the starting point.

From a clinical standpoint tubercular peritonitis may be considered under two heads:

1. Those cases of tubercular ascites in which the exudation of serous or sero-sanguineous fluid is the predominant feature. The exudation is preceded or accompanied by the eruption of miliary nodules, involving more or less of the peritoneal surface.

2. Those cases in which tumor formation is the distinctive feature. The diagnosis in the first class of cases can only be made when we exclude all other possible causes of ascites. There are however some points relative to the occurrence of tubercular ascites which should receive careful consideration.

The history, frequently of some antecedent tubercular lesion, especially of the intestine or genital organs.

The age of the patient, tubercular peritonitis occurring most frequently between the ages of 20 and 40 years. However, it may occur at any age, being relatively common in children, where it is often associated with intestinal disease.

Sex.—It is undoubtedly more prevalent in the female. Koenig collected 131 cases, of which 120 were females and eleven males. In the cases of Osler, Boulland, Häne and Maurange taken together, there were sixty males and 131 females.

Temperature.—Osler calls attention to the fact that the temperature in this form of peritoneal tuberculosis is frequently subnormal, varying from 95.5 to 97 degrees. At times the temperature is normal, or it may be slightly above normal, although this is not the rule.

Pigmentation, especially of the face, is occasionally noted in tubercular peritonitis. This may occur when the adrenals are not affected, as in a case reported by Osler.

Onset of the disease.—This may vary between those in which the onset is exceedingly acute, resembling suppurative peritonitis, or acute intestinal obstruction, and those in which the process is extremely latent, where a gradually increasing exudation is for a long time the only symptom. In many cases the recognition of the disease is accidental, there being no distinctive symptoms to point to its true nature.

Emaciation, loss of appetite and diarrhea are symptoms which vary with the acuteness of the disease, being more pronounced where the onset is rapid and the exudation great.

The relative frequency of the ascitic form of tubercular peritonitis is shown by the cases observed by Biat (cited by Osler). Of the eighty one cases analyzed by him, in thirteen there was extensive ascites. A moderate amount of fluid, however, is often observed in all forms of the disease.

Tumor formations, the result of tubercular peritonitis, although quite common, present great difficulty in the way of diagnosis. These tumors may originate in four different ways.

1. Tumors composed of rolls of omentum, which are the result of an extremely chronic inflammatory process which chiefly affects the omentum. These tumors are ridge-like in form, lying transversely across the upper part of the abdomen. They are seldom associated with any considerable amount of exudate.

The diagnosis of this condition is frequently difficult and at times it has been mistaken for carcinoma. The history of the patient, especially if there should be a predisposition to tuberculosis, or the presence of other tubercular lesions, the most frequent of which is tubercular pleurisy, should guide us in making our diagnosis. The presence of an area giving a resonant percussion note just above the mass is of value in differentiating these tumors from tumors of the liver, for which they are often mistaken.

2. Abdominal tumors produced by sacculated exudations are the most common form, as well as the ones that present the greatest difficulty in diagnosis. The fluid found in these cavities may be either serofibrinous or purulent, representing different stages of the same disease. Again, the tumor may be regular in outline when it is entirely fluid, or irregular and nodular when composed in part of cakes of lymph or omentum. These tumors may be found anywhere, but usually occupy the middle zone of the abdomen, where they have many times been regarded as tumors of the ovary, either cystic or solid. There is no way of positively distinguishing between the sacculated effusions of tubercular peritonitis and cystic tumors of the abdomen. We should consider carefully the history particularly of tubercular disease in the family or of old tubercular lesions. Abdominal pain and irregularity of the bowels are more common than in ovarian disease. The onset is usually gradual and the general health remains fair for some time. In

some cases we have an early loss of appetite, emaciation and diarrhea associated with an irregular temperature. The physical signs are exceptionally deceptive. In typical cases they are identical with cystic ovarian disease. In cases where the exudate is small, the outline is not nearly so distinct as in ovarian tumors, while the form and position may change at any time, owing to the alterations in position of the intestinal coils that go to form the walls of the tumor. Irregularities in the periphery of the tumor, due to tubercular nodules and cheesy masses, are of great value in determining the nature of these tumors. The condition of other organs should receive particularly close attention, especially the pleura, lungs and genital organs.

3. Tumors formed from matting together of coils of intestine may simulate either solid or cystic abdominal growths. They may be adherent or freely movable and may occupy any part of the abdominal cavity. Mistakes in diagnosis in these cases, although they occasionally occur, are not nearly so common as in sacculated exudations. In making a diagnosis we have the history, the rapid emaciation, irregularity of the bowels and an irregular temperature. The physical examination of the abdomen shows irregular areas of tympany and dullness, with more or less nodular, irregular tumors. At times, there is free abdominal fluid.

4. Enlarged mesenteric or retroperitoneal glands may closely simulate other solid abdominal tumors. This condition is much less common than the other tumors of tubercular origin. They may vary in size from that of a walnut to masses larger than a child's head. Frequently they can easily be palpated, but occasionally the presence of free abdominal fluid or of excessive tympanites may prevent their recognition. The nodular character and number of these tumors together with the presence of fluid free in the abdominal cavity and the history are usually sufficient to make a diagnosis. Irregular tympanitic areas and persistent diarrhea with rapid emaciation are frequently associated with this form of the disease.

In former years it was generally held that no case of abdominal tuberculosis ever recovered. At present we know that this is far from being true. Many cases undoubtedly recover either spontaneously or under medical treatment.

Foullard collected eighty-two cases from the older literature of which twenty recovered. Some of these patients were in good health from ten to seventeen years after recovery was apparent. The diagnosis in these cases was, however, based upon clinical evidence alone, and not supported by any bacteriologic examination. We are justified, therefore, in assuming that a part of these at least were not cases of tubercular peritonitis.

At the present time, knowing that such good results may be expected after laparotomy, nearly all of the profession are agreed that all of these cases should be subjected to operative treatment. The method of procedure adopted by most surgeons in the ascitic form of the disease is to simply open the abdomen by immediate incision, evacuate the fluid and drain. Some irrigate the abdominal cavity with a mild antiseptic solution, while others apply antiseptics, in a concentrated form, directly to the diseased surface. Rendu employs a solution of camphor naphthol which he brushes over the affected surface. This solution is claimed by M. Perrier to be distinctly antagonistic to the tubercle bacilli. Direct medication applied to the miliary tubercles of iodoform, either dry or in the form of an emulsion, has been employed by many surgeons. It is questionable whether these methods of direct medication add any to the chances of a cure after laparotomy. Statistics show that most of the cases cured have been of the acute miliary variety with ascites, and that the treatment followed was simply incision and drainage.

The method of evacuating the fluid through a canula and subsequent filling of the abdominal cavity with sterilized air, as recommended by von Mosetig, has given a few cures.

In the chronic fibrous or the ulcerated forms the chances of a cure are not as good as in the acute miliary form with ascites. An attempt should always be made in these cases to remove as much of the caseating mass as possible. This should be followed by the free use of iodoform and drainage.

The percentage of cures after celiotomy for tuberculosis varies from 25 to 70 per cent. in the cases reported by various surgeons up to the present time. Kummel collected thirty cases, beginning with the first operated on by Spencer Welle in 1862. Of these there were twenty-five cures of from nine months to twenty-five years duration. Koenig collected 131 cases, of whom 75 per cent. were greatly benefited and 25 per cent. permanently cured. Aldibert reviewed 308 cases. Of these, 2.5 per cent. died as the immediate result of the operation, and 215, or 69.8 per cent. were cured. The largest number of operated cases (358) has been collected by Roersch, Of

these, 250 or 70 per cent. were permanently cured by laparotomy.

The way in which healing takes place in tubercular peritonitis has been studied both from postmortem examination of partially healed tubercular lesions and from cases on which a second operation has been performed.

In 1895 Jordan studied fifteen cases on four of which post-mortem examination was made some time after the abdomen had been opened. In eleven the tissue examined had been secured at a second operation. He concluded that healing took place as a result of an active tissue proliferation by which the essential elements of the tubercle were compressed and destroyed. Pichini, Bumm and Osler found connective tissue displacing the cellular elements of the tubercle, beginning first in the periphery, and later extending to the center of the nodule. Riva found connective tissue substituted for the tubercle, but maintained that the proliferation began in the center and not in the periphery of the nodule. He also asserts that the formation of connective tissue was preceded by a degeneration of the central cells of the tubercle.

In two cases which had been subjected to a second laparotomy, Mazzoni found the tubercles surrounded by a zone of inflammatory exudate which was the result of an increased vascularization of the parts that followed the operation. In the center of the tubercle vacuolation and degeneration of the epithelioid cells were observed. In other parts, where the healing process was more advanced, connective tissue had taken the place of these central cells.

Gatti (*Arch. f. klin. Chir.*, 1896), after an extended series of experiments on animals, concludes that the tubercular lesions found in the peritoneum healed not by proliferation of connective tissue, the result of an active inflammatory reaction, but as the result of hydropic degeneration which first affects the protoplasm and then the nuclei of the epithelioid cells. These cells subsequently are absorbed along with which the bacilli and round cells gradually disappear, leaving only the pre-existing connective tissue stroma with its vessels.

The reason for the cure of tubercular peritonitis after laparotomy and the way in which retrograde degeneration and absorption of the essential elements of the tubercle are brought about is yet a subject of dispute. Various theories have been advanced, prominent among which may be mentioned the following: 1. The action of the anesthetic; 2. Psychic influence; 3. Operation trauma; 4. Removal of the ascitic fluid, depriving the tubercle bacilli of their nourishing medium; 5. Increasing the absorption possibilities of the peritoneum; 6. Removal of ascitic fluid containing ptomains; 7. Inflammatory reaction following entrance of air; 8. Diminution of the vitality of tubercle bacilli by aseptic inflammatory reaction which follows opening the abdomen.

Gatti considers that as a result of simple laparotomy there follows a serous exudation in the peritoneal cavity which exerts an unfavorable influence on tubercle bacilli destroying them completely or so affecting their vitality that they subsequently die and are absorbed.

(To be continued.)

American Medico-Psychological Association.

Fifty-fourth Annual Session held at the Southern Hotel, at St. Louis, Mo., May 10-13, 1898.

FIRST DAY—MORNING SESSION.

The Association was called to order at 10 A.M., Dr. R. M. BUCKE, the President in the chair; Dr. C. B. BURR, Secretary.

Dr. C. R. WOODSON, Chairman of the Committee of Arrangements, announced the unavoidable absence of Governor Stephens, whose regrets were read, and introduced the Hon. HENRY ZIEGENHEIN, Mayor of St. Louis, who in a few humorous and well received remarks welcomed the Association to St. Louis, to the hospitalities of its institutions, and promised them the protection of the Mayor.

Dr. MAX C. STARKLOFF, Health Commissioner, welcomed the Association on behalf of the Department of Health, and Dr. C. H. HUGHES on behalf of the medical profession.

President BUCKE replied briefly to the address of welcome, after which a recess was taken.

The following were appointed as the Nominating Committee: C. P. Bancroft, T. J. W. Burgess and P. L. Murphy.

The address of the President which followed, had for its subject

SURGERY IN THE INSANE IN CANADA.

The Doctor apologized for introducing a subject that he had already treated two years before, but his experience had greatly widened within that time and his views expanded. He referred to the experience of Drs. Hall and Burgess and of Dr. Holmes, who had twenty four recoveries from puerperal insanity by the relief of surgical disorders. Many of the best men in the profession are coming to the opinion that there is a closer relation between genital disturbances and insanity than has been heretofore suspected. Dr. Kellogg, alone, amongst systematic writers on insanity, recognizes this fact. The point which he wished to emphasize was that there exists in insane women a vast amount of unrecognized pelvic disease that ought to be relieved, and that this belief is becoming general in the medical profession, to our discredit. Some three years ago there was initiated in the London asylum, a work of this kind under disadvantages from lack of government aid, and to further the work he issued a circular to the physicians in his asylum district, asking if in their opinion, the work should be continued and receive government aid. Out of 300 addressed, he had 250 replies and of these, 205 thoroughly approved and answered in the affirmative. If such a wide spread belief exists, we should not reject it as unfounded, without good reason. There may be differences in this respect in asylums, but this should be claimed only upon proof. It is the duty of asylum physicians to make sure of the facts and this is of the utmost importance. In the London asylum they had operated so far on 109 women for 309 diseased conditions, with a total of 195 operations. In no case did they trust to their own diagnosis but always had the co-operation of skilled specialists. The results were thirty-nine mental recoveries, thirty-five improved and thirty-five unimproved. In nearly all, the physical condition was markedly bettered; there were only three deaths. In thirty-two non-gynecologic cases the physical results of operation were always good but in none was there decided mental improvement. As regards the conditions, the relief of which appeared to be most often followed by mental betterment, the morbid states of the ovaries, the cervix and the endometrium, in the order named seemed of the most importance. The theory of internal secretion was suggested as partly accounting for the apparent ovarian influence, a perverted secretion from a diseased organ acting on the brain. The address concluded with the expression of the opinion that when the eyes of the profession are generally opened as to these facts, an important step would be made in the prophylaxis of mental diseases in women.

FIRST DAY—AFTERNOON SESSION.

The first paper was by Dr. C. H. HUGHES on "Insanity Defined on the Basis of Disease." He discussed the definition of insanity as indicating the clearness of the conception by different authorities at various periods, showing that there had been a gradual progress toward a clearer and truer notion of the state, while with the latest advances in nerve physiology and anatomy, we now stand on more certain ground and the relations of the cortical to the mental disorders are clearly established.

Dr. E. C. RUNGE read a paper on

THE SCIENTIFIC BORDER LINE BETWEEN SANITY AND INSANITY.

He stated that we are safe in assuming that certain cortical centers are essential for psychic functions and excluding teratologic conditions we may admit the disorder of these as what we call insanity. He objected to the exclusion of artificial or voluntary toxic mental derangements, and said the distinction between delirium of acute disease and insanity is purely arbitrary. Collections of data as to the influence of heredity in delirium are highly desirable in this connection. The paper was a criticism of the common practice of limiting insanity to more or less lasting afebrile mental disorders and excluding such conditions as delirium, acute intoxications, etc. The distinction of psychoses into symptomatic and essential is also indefensible. His conclusions were:

1. Insanity is a symptom of any pathologic process involving the psychic centers of the brain, hence the border line between sanity and insanity lies at the point where brain disease parts way from brain health, by brain meaning the psychic centers.

2. The words insanity and insane should apply to any condition manifesting psychic deviations from normal psychic functions. It objectionable we should not hesitate to eradicate these terms and find others less obvious. The disappearance from our scientific vernacular of these words would be hailed with general satisfaction, as they carry with them an atmosphere of medieval superstition and prejudice.

3. Such views as propounded in the foregoing would assist in dispelling the worst misconceptions of insanity and the

insane. No opportunity for their systematic propagation should be missed. After insanity is once for all accepted as a symptom of actual disease of the brain, a disease like any other, amenable to treatment, we who are fighting for the rational and humanitarian methods, will meet with fewer obstacles in our effort to obtain what we need for the successful achievement of our aims.

In discussion of these papers, Dr. HURD said that the distinction between insanity and delirium is an artificial one, yet has a practical value. It has been shown that the same functional changes occur in the brain as in other organs. It is best, however, to go slowly before generalizing and have more facts. The future was hopeful. The papers were also discussed by Drs. Tomlinson, Russell, Eskridge and Dewey, and Drs. Runge and Hughes closed the discussion.

Dr. H. M. BANNISTER read a paper on "The Hospital Medical Library." After stating the need of this in the care of the insane, he gave details of what he considered essential in a hospital reference library and estimated roughly the expense of procuring and maintaining such.

Dr. BRUSH described the card subject catalogue in use in the Sheppard Asylum.

FIRST DAY—EVENING SESSION.

Dr. A. M. EDWARDS read a paper by Dr. D. R. BROWER, entitled "The Judicious Training of Neurotic Children as Aid to the Prophylaxis of Insanity." It said that for the last four years nervous diseases have stood at the head of the mortality lists in Chicago. He agreed with Regis in the estimate of heredity. By successful management of pregnancy, insanity of the offspring may sometimes be nipped in the bud. After birth, prophylaxis must include removal from unfavorable surroundings, country life best; education not forced; physical training, etc.; during childhood and adolescence, the same principles, abstinence from stimulants, sexual hygiene, etc.; later, when occupation is chosen it should be for these cases more of an automatic character and out of doors, not taxing the mind.

Dr. H. A. TOMLINSON read a paper on "The Etiology and Pathology of Diseases of the Lungs among the Insane." Its proper title, he stated, should be "the natural history of tuberculosis in the insane." He gave an account of experience with tuberculosis in the Rochester State Hospital (Minn.). At first comparatively free from the disease, they had had within a very few years fifty deaths from this cause, on thirty-four of which autopsies were made. The predominant type was a degenerate connective tissue type, occurring mainly in old chronic cases who were free from the disease on admission. The original defectives were the greatest sufferers and, next to these, the senile cases. The phthisis often exists long before tubercle bacilli can be found and another peculiarity is the absence of hemoptysis. The degenerative changes in fifty tuberculosis cases were practically the same as those in the insane. Besides this connective tissue type there was, in a few instances, an acute catarrhal form, which was not usually fatal.

Dr. H. M. HURD considered this subject the most important one likely to be brought before the session. He referred to Dr. J. W. Babcock's researches on infected buildings, and had requested him to investigate further and asked the co-operation of the Association. He was not quite clear as to what Dr. Tomlinson meant by degenerations. He thought the cocci in the abscesses not important and believed that in demented cases we often had a sort of aspiration pneumonia. Proper surroundings, diet, exercise, etc., are important, tuberculosis is the termination of neglected insanity.

Dr. LYMAN had found, in the Mendota herd, thirty-eight out of seventy cows tuberculous, but there had been no spread of phthisis and their deaths from this cause were very few. He believed infected buildings more dangerous than infected herds.

Dr. HILL of Maryland reported finding the walls of a general hospital thoroughly infected with tubercle bacilli. He believed that in formaldehyde we had an efficient agent with which to combat this infection and held that a rigid onslaught on the germs and constant and careful observation were the only means of combatting phthisis in asylums.

Dr. TOMLINSON, in closing the discussion, said he had not meant to cover in his paper all the points raised, but to point to some of the peculiarities of tuberculosis in the insane, the fibrosis, etc., and to ask for the reason: in another type there was a rapid epithelial degeneration and he wished to call attention to these two groups. Speaking of infection, he mentioned the difficulties in managing with this class of patients. The staphylococci were important as causing supuration and the tubercular symptoms; with no overcrowding there would be little or no tuberculosis; with it tuberculosis would appear.

(To be continued.)

Association of American Physicians.

Thirteenth Annual Meeting, held in Washington, D. C.,

May 3, 4 and 5, 1898.

(Concluded from page 1230.)

Dr. WM. OSLER of Baltimore, then related two cases of

PARALYSIS OF THE LEFT RECURRENT LARYNGEAL NERVE IN MITRAL STENOSIS.

He thought these cases were interesting because they brought out some clinical points to which reference has not yet been made in the literature, so far as he knows. One case was that of a young woman with signs of cardiac failure, edema, and she had complete recurrent paralysis. There was nothing to indicate any pressure in the thorax; there was no tumor. He saw this case several times when the heart was quiet. He made the diagnosis of paralysis of the left recurrent laryngeal nerve, and left the question of the cause of the other trouble out. Later on the patient went abroad, and he gave her a letter to Dr. Nothnagel of Vienna, who also thought there was local pressure but could not find it. The patient lived until last summer from 1891 when he saw her, and had several recurrences. In 1892 he had another case, a young woman, the daughter of a physician. She had had scarlet fever. She died a year later. There was no autopsy in either of these cases. A few months ago in the *Wiener klinische Monatschrift* a case was described in which he believed the conditions were due to pressure of the distended left auricle on the recurrent laryngeal nerve. It was first thought to be aneurysm, but the autopsy showed the left auricle to be enlarged. Dr. Herrick told him he had had a case in which the nerve was compressed by the pushing aside of the left bronchus and other tissues and the left auricle pressed on the nerve and there was also adherent pericarditis. This was an interesting point and would help to clear up doubtful diagnosis in such cases where the nerve is compressed.

Dr. E. G. JANEWAY of New York then read a paper entitled,

TWO ATTACKS OF TEMPORARY HEMIPLEGIA OCCURRING IN THE SAME INDIVIDUAL AND THE RESULT OF THE USE OF PEROXID OF HYDROGEN IN A SACCULATED EMPYEMA (PLEURAL).

The patient was a man 41 years old, right-handed. He had pleurisy on the left side. A year and a half later it was necessary to take out one of his ribs on account of a sinus there. This was irrigated with peroxid of hydrogen. Some time after this while using this material he became unconscious. His right arm and leg and one of his feet were paralyzed but he recovered in twenty-five minutes, well in every other way but very much frightened. In three days after this, under similar circumstances, he had another attack. He lost power in his neck this time and his head drooped over. It lasted twenty-five minutes. The sinus closed. Physical signs were few and not easily found. His respiration was somewhat freer on that side. Large râles were found to follow coughing; in examining this case, he used the stethoscope, the phonendoscope and his ear, and found that when the lesion was deep in the lung, as in this case, the ear was better than any instrument. The second case he had was a man 21 years old, who had pleurisy on the left side. He had to be operated on, a rib removed, and a fistula remained. At the end of four months the sac was washed out with water and tincture of iodine, and some time after that, while washing out this cavity, he was unable to speak, but retained consciousness. It did not last very long. There were two other attacks. He also quoted a case from French literature. Lavage in several cases caused the same kind of paralysis, and in a very short time recovery followed. There was no aphasia. In fatal cases no embolism was found. There was collapse but the paralysis was only temporary. This is much like pleuritic epilepsy. In one case which he quoted there was aphasia. There may be temporary embolism from pressure of the sac on liberation of the oxygen. The air or gases in the sac may have caused this. He referred to the case of Dr. Lewin, which was called air embolism, in which the air entered the bladder thence into the kidney and then into the circulation. This case was rather unusual and hard to explain.

Dr. MELTZER then said that this might be similar to attacks after washing out the stomach. Pressure on the nerves produced these attacks and it is more felt in the beginning of the washing.

Dr. HENRY HUN of Albany, related a case to show that all cases are not due to air embolism. In this case there was caries of the spine, and peroxid of hydrogen was injected to wash out the sac, but did not escape. Paralysis lasted three hours. It may have gotten into the spinal canal.

Dr. JANEWAY said, in conclusion, that the interesting feature in his cases was that the pleurisy was on the left side and the paralysis on the right and that the cases were right-handed. When we infer that the lesion must have been on the other side, we must consider this a cerebral accident, and that perhaps something has been transmitted to the brain causing this. Almost all these cases are accidental and happen after the sac becomes small, the reflex theory hardly holds.

URIC ACID DIATHESIS AN IMPORTANT FACTOR IN PATHOLOGY was then taken up by Dr. V. C. VAUGHAN of Ann Arbor, Mich. He spoke on the physiologic chemistry. He said that uric acid was eliminated when the spleen nuclein is broken up. It was formerly thought to be the product of imperfect oxidation. The formation of uric acid is the measure of nuclein metabolism. He asks what the chemic constituents of the nuclein cells are. No two cells of nuclein have definite composition. Some light has been thrown on this subject by the study of lymphocytes, and nucleic acid is the most important constituent of nuclein and this contains much phosphorus. He quoted further from the work by Lilienfel, and went very thoroughly into the chemistry of nucleic acid. Nuclein disintegration is necessary for the production of nucleic acid. The nucleus is the important part of the cells and that which makes life potentially continuous. Some cells only exist for the formation of other cells. Thus, the nucleus having formed, the red blood corpuscles disappear. The leucocytes are the quantitative or varying source of uric acid in the body. There may be hypo-leucocytosis with an increase or an elimination of the alloxuria, but there is no increase of the uric acid. It is not claimed that the xanthin base is broken up and yields uric acid.

Dr. WM. H. DRAPER of New York, then spoke of the uric acid diathesis from a clinical standpoint. He reviewed the older ideas on the subject of uric acid diathesis, and spoke first of gout, and referred to Garrod's work. He said that uric acid may be in the blood when there is no gout, and there may be gout with no apparent presence of uric acid in the blood. Inflammatory rheumatism is now considered a specific disease, perhaps of bacterial origin. The joint structures are especially vulnerable. Men seem to have gout and women rheumatism. The disease is hereditary. Uric acid does not seem to be the cause of gout. Rheumatism is hereditary, but the tendency to it may be aroused by errors in food and diet. Gout is especially liable to affect persons who have a tendency to it; also diseases such as tonsillitis, pharyngitis, urticaria are also a complication and may be brought on after eating strawberries, apples, taking wine, beer, etc. Pruritus is another symptom often observed in cases of weakened constitution. Skin diseases often occur in diabetes. The salicylates probably have a paralyzing effect on the metabolism. Clinical observation is alone necessary to solve this problem, but the clinical observer of the present day must be better prepared than the practitioner of twenty-five years ago. The instruction in chemistry is better now in the schools than it used to be. If there were fewer drug stores and better laboratories for helping physicians in making diagnosis the advantages of treatment would be much better.

THIRD DAY.

Dr. A. H. SMITH of New York, in an article entitled

THE ANTITOXIN TREATMENT OF PNEUMONIA,

summarized all the work on this subject that so far has been published, and summed up the results obtained by different authors. The difficulties of securing an antitoxin for this disease were touched upon, and the most that could be said for the work at present was that it possibly offers some encouragement.

Dr. WILLIAM H. WELCH said that it was difficult to find even a toxin in pneumonia, and at present there is absolutely no scientific basis for a pneumonia antitoxin.

Dr. V. C. VAUGHAN said that he had done a good deal on this subject, and that up to the present time immunity experiments had been of limited value and offered no promise of therapeutic use.

Dr. C. G. STOCKTON referred to the relation of leukocytosis to the crisis of lobar pneumonia.

Dr. W. S. THAYER contributed his experience to show that there was a marked difference in the way in which leukocytosis behaved with regard to the pneumonia crisis. He believed that the fall in leukocytosis depended more upon the rapidity with which the lung consolidation cleared up than upon any change in temperature.

A CASE OF CHRONIC INFECTIVE ENDOCARDITIS WITH STREPTOCOCCI FOUND IN THE BLOOD BEFORE DEATH. TREATED WITH ANTISTREPTOCOCCUS SERUM AND EXPERIMENTS ON THE EFFECTS OF INJECTIONS OF SERUM AND OF ANTITOXINS UPON THE KIDNEYS.

Dr. W. H. THOMSON of New York, related the case of a patient, aged 36 years, who was affected for seven months with periodic attacks of an intermittent fever ushered in by pronounced rigors. On other occasions he would suffer from periodic neuralgias in the forehead and left hypochondrium without rise in temperature. No late cardiac lesion could be determined, because of a loud murmur due to congenital malformation of the right heart. There were no lesions which would point to infective endocarditis, but an examination of the blood from the median vein showed numerous streptococci. The antistreptococcus serum treatment was used without benefit. Death followed with symptoms of acute nephritis.

Dr. J. E. GRAHAM reported two cases of septicemia, in which the antistreptococcus serum treatment was followed by recovery.

Dr. W. S. THAYER referred to the similarity of the temperature curve in this affection to that of quotidian fever, but believed that the differentiation could always be made by the more exact periodicity of paroxysms in the malarial chart, by the larger count of red blood corpuscles in septicemia and by the action of quinin, which is an absolute specific for malaria.

STUDIES OF ANTITOXINS FOR TUBERCULOSIS.

Drs. E. L. TRUDEAU and E. R. BALDWIN of Saranac Lake, detailed their attempts to produce an antitoxic and curative serum for tuberculosis; also their tests on animals of the efficacy of serums already produced by others. The first part of the paper describes the authors' methods and attempts at producing an antitoxic serum in various animals, sheep, fowls, asses and rabbits, as well as the tests used to study experimentally any curative properties supposed to have been developed in such serums. The second part of the paper sets forth the tests on animals of the antitoxic power of the serums obtained by the authors, and of some other serums already on the market, or furnished to them for experiments. Their work covered more than four years, and observations were made on 4 sheep, 3 asses, 12 fowls, 18 rabbits and 450 guinea-pigs. Their results show that in one or two of the serums tested a slight degree of antitoxic power might be present, but in all others the tests were negative. They were unable to obtain any germicidal or curative influence from any of their serums. In the opinion of the writers, the outlook for an efficient tuberculosis antitoxin is by no means a hopeless one, in view of the recent contributions by Ehrlich, Wassermann and Behring to our knowledge of the mechanism of immunity and antitoxin production in the body.

Dr. H. C. ERNST of Boston, read a paper on

THE EFFECTS OF FREEZING ON DIPHTHERIA ANTITOXIN.

He found that after freezing diphtheria antitoxin for from two to three days it separated into several layers of different density, and on testing the immunizing power of these different layers it was determined that the upper layers had lost nearly all of their antitoxic properties, while the lower layers had greatly gained in power. The freezing seems to have the power of precipitating the antitoxic element.

In reply to a question by Dr. Vaughan, Dr. Ernst stated that it could not be determined with absolute accuracy whether there had been any loss of antitoxic property in the total amount of serum in the tube, but there seemed to be no such loss.

The following officers were elected to serve for the ensuing year: President, G. Baumgarten; vice-president, E. G. Jaueway; recorder, I. Minis Hays; secretary, Henry Hun; treasurer, W. W. Johnston; councillor, J. C. Wilson; representative on executive committee of Congress of American Physicians and Surgeons, William Osler; alternative representative, C. F. Folsom.

Action of Atropin and Pilocarpin on Peristalsis.—Traversa being struck by the fact that injections of atropin caused constipation rather than increased emission of feces in horses, has investigated the action of this drug and also of pilocarpin. It was found that pilocarpin accelerated and strengthened peristalsis, while atropin lessened and finally abolished the movements of the intestine. In each case the result is obtained through paralysis or stimulation of the ganglia and nerve endings in the intestine. From this it follows that belladonna is not likely to be of value in constipation from atony of the bowel muscle, but in lead colic where it is not improbable that the intestinal ganglia are irritated, belladonna may prove a useful remedy, and indeed in all cases when painful intestinal spasm, due to irritability of the intestinal ganglia, is present, the drug in question may be used with advantage. —*British Medical Jour.*

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance	\$5.00
Foreign Postage	1.75
Single Copies	10 Cents.

In requesting change of address, give *old* as well as new location.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, 100 Washington St., Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

SATURDAY, MAY 28, 1898.

THE ACCLIMATIZATION OF THE WHITE RACE IN THE TROPICS.

It has become almost a matter of universal belief that the tropical regions are unfit for the permanent abode of the white race; that Europeans or Americans transplanted to such regions sooner or later succumb to the effects of the climate, or if they survive they and their descendants deteriorate physically, mentally and morally. Only in exceptional localities where the climate is modified by elevation is it generally held that the white race can prosper and retain the qualities that have given it the prominence above all the other races of the earth. Good people taking the teleologic point of view have argued that as the greater portion of the continents lies north of the tropics, it was not intended that mankind should flourish in the central latitudes, forgetting for the time that all early Biblical history is laid in at least subtropical regions. There or in still more equatorial regions man undoubtedly originated and he is, in a manner, an exotic in the colder portions of the earth. Even the upholders of the most literal interpretation of the Mosaic record could hardly plant the garden of Eden in a wintry climate or one even subject to occasional rigors. Man in a state of nature is a tropical animal unfitted for the harsher temperature of our so-called temperate latitudes, and the Eskimo or other dweller of still more boreal regions draws out a hard and unnatural existence under conditions for which his acquired fitness is at best only a partial one. Life is really harder the farther we retreat from the tropical or warm temperate climates, though the stimulant and selective effect of the struggle for existence

has undoubtedly improved the race and led to the contrivance of thousands of artificial luxuries to make life tolerable and enjoyable for those that can obtain them. Upon the very poor, however, the hardships of our climate bear down as severely as if they were not mitigated to those better off, and the aggregate of human misery is increased.

Now that the available temperate regions of the earth are nearly occupied and civilized nations are reaching out in all directions to appropriate every unoccupied territory, the question of the adaptability of the tropics as a dwelling for our race comes prominently to the front. If it can be shown that the warmer regions are not inhospitable and deadly to the whites, that they are even not unfitted for white labor, an important fact has been gained bearing on the welfare of our race.

There are some grounds at the present time for believing that this may be true, and that the popularly accepted views of the past and which still prevail are incorrect. The *British Medical Journal* of April 30 contains an interesting abstract of a recent discussion in the Royal Geographical Society bearing upon this point. Dr. SAMBON read before the Society a paper taking the ground that the possibility of the white race becoming acclimated in the tropics can not be questioned, now that our ideas of sanitation, and the cause of disease have so materially widened within the past few years. The so-called special tropical disorders, anemia, liver abscess and sunstroke, are all, he held, including even the last-named, microbial diseases, and not due to the heat or other essential element of the climate. All are forms of deterioration due to definite microbial infection and are, or undoubtedly soon will be, thoroughly met by properly adapted sanitary measures. Deterioration of the race, he claimed, is only a symptom of failure due to slowly progressive disease, and it is far less serious in the warm climates of the earth than in the crowded urban populations of our great centers of civilization. Infant mortality is less in the worst tropical regions than in some European countries; farm labor is carried on without detriment or distress by white men in India, South Africa, tropical Australia and Central America. Any racial immunity that could be said to exist anywhere was really an acquired one, and there is no reason to suppose that, with our present and rapidly increasing knowledge of disease and its causes, the individual should not also learn how to be immune.

There is no doubt that climate has in time an effect upon individuals and upon races, but it is hard to prove that it is necessarily a deleterious one, as has been so commonly assumed in the case of the white race in torrid regions. The supposed facts upon which this notion is based are coming to be found not essentially true, and it is not improbable that all the so-called tropical diseases will be found in time to be

avoidable ones, even under the conditions of active life and labor in the warmer parts of the world. The fact that in the discussion of Dr. SAMBON'S paper, Dr. MANSON, who is not to be considered inexperienced with tropical disorders, announced that he had completely changed the views which he had formerly held on this point and now believes that, accepting the germ theory of disease, there is no reason to consider the tropics as essentially unhealthy for Europeans, has a certain value as giving the weight of his authority on this side of the question. Yellow fever we have long known to be an avoidable disease with proper sanitation, and the experience of many parts of our own country has shown us that the ordinary forms of malaria are eradicable by cultivation and settlement. On the other hand a retrograding civilization and human neglect have made pestilent morasses of formerly populous and healthy regions. While man is to some extent subject to disease by climate, in his civilized condition he modifies nature to meet his wants and it is easy to believe that with his increasing knowledge of sanitation he may overcome the natural disadvantages that work against him in tropical lands. There are too few of these that can be said to be at present altogether occupied by an unmixed white race, the experiment is therefore yet to be tried, but there is little doubt of the result.

One great trouble with the acclimatization of white men in hot countries has been their personal habits and lack of attention to ordinary hygienic precautions. The use of alcohol and other forms of dissipation have also contributed to their failure in many cases where the climate has been credited with the result. No one can say that the original missionary stock has deteriorated in the Hawaiian Islands or that its descendants are not at the present time creditable representatives of the Anglo-Saxon race. India, where it has been said the English race does not propagate itself, has nevertheless given us some of the most brilliant minds of our century; THACKERAY and RUDYARD KIPLING being familiar examples, and others might be mentioned. That man does not necessarily degenerate intellectually is also proven by the Hindoo stock; that is certainly acute enough, though deficient in other respects. How much these defects are due to the climate as opposed to centuries of despotism, superstition and other deteriorating influences can not be readily estimated—there are too many elements in the problem for its offhand solution.

It is said that life in hot countries saps the energies and thus produces degeneracy. That this is a fact to some extent may be accounted for by the ease of obtaining a livelihood and it is not necessary to call in the influence of climate in other ways. Sir CHARLES DILKE considered the banana the curse of the tropics; a man who does not have to work will not always be energetic, and if a square rod or two of land supports him there is many a one who will ask

for no more. But that this would be the effect on an energetic white race, accustomed to civilization and its demands is another question, and one that is disputed by the facts. The problem of healthfulness once solved, the rest will answer for itself and the opening of the richest regions of the earth to European settlement is probably only a question of time and of sanitation.

TWISTING OF THE UTERUS BY TUMORS.

Tumors which grow from the pelvis into the abdominal cavity and thus get more room, such as tumors of the ovary provided with a long pedicle, not infrequently present torsion of the pedicle that give rise to very acute symptoms. Pedunculated myomata of the uterus may also present torsions of the pedicle, followed by necrosis of the tumor.

B. S. SCHULTZE¹ calls attention to the fact that these torsions of the pedicle of tumors connected with the uterus or its appendages are not always sharply enough distinguished from twists of the axis of the uterus. The term torsion of the uterus was first applied by KLOB to describe a changed position in the whole uterus, which is brought about by parametric cicatrices, which dislocate the entire uterus as well as the cervix. Thus gynecologists speak of dextro-torsion and sinistro-torsion of the uterus.

The twisting of the uterus around its long axis, which may be due to the presence of tumors in the uterus or its immediate vicinity, gives rise to entirely different conditions, because in the last case the cervix remains stationary. The twisting occurs at the junction of the body with the cervix.

SCHULTZE found twenty-six cases of this twisting of the axis of the uterus reported in the literature. To these SCHULTZE adds six new cases of his own. Of the total of thirty-two cases, fifteen concerned myoma of the uterus, seventeen tumors of the ovary. In the cases of myoma of the uterus the twisting in one case was less than 180 degrees, in eight cases about 180 degrees, and in two cases the twisting amounted to four times 180 degrees. In the ovarian cases the twisting generally amounted to about 180 degrees.

The puerperal state favors twisting of the uterus in cases complicated by ovarian tumors. In these cases it seems to concern a continuation of the twisting of the pedicle of the tumor into the body of the uterus, as the tumor rises into the abdominal cavity, in which there is abundant room after childbirth; the room is sufficiently ample to allow the tumor to twist its pedicle. This is especially liable to happen when, as is not infrequently the case, one side of the ovarian cyst is heavier than the other, and when the cyst pedicle is rather long. The movements of the patient may assist in twisting the pedicle, especially

¹ Ueber Axendrehung des Uterus durch Geschwülste, Arch. Geburtshilfe und Gynaekologie, xxxviii, 1, 1898.

when she takes pains to voluntarily so place the tumor that as little discomfort as possible is produced. Twisting of the uterus is favored in the puerperal state also, on account of the soft consistency of the uterine tissues. SWITALSKI² describes a case illustrating these conditions, resulting in acute circulatory and nutritive disturbances in the tumor and in the corresponding part of the uterus. In other cases of this kind the last pregnancy occurred too long previously to have any etiologic connection with the twisting of the axis of the uterus. SCHULTZE also describes a case in which twisting of a myomatous uterus after pregnancy occurred. In many cases the size of the tumor is such that the abdominal walls become flabby and atrophic. In some cases ascites may coexist, and under such conditions a spontaneous axis-twisting of the uterus may occur.

The symptoms of axis-twisting of the uterus are naturally difficult to separate from the symptoms of the tumor. As is well known, twisting of the pedicle of an ovarian tumor may give rise to passive congestion, hemorrhage and necrosis of the tumor, in consequence of which peritonitis and other disturbances may occur. Ovarian tumors with short, untwisted pedicles, which are adherent in the pelvis, may cause serious symptoms of pressure upon the adjacent organs, and when there is simultaneous twisting of the axis of the uterus, it may be difficult to decide whether the symptoms are due to compression of the tumor or depend upon twisting of the uterus. Operation would decide such questions and remove the factors that give rise to symptoms.

It seems that the disturbances of the urinary bladder are not infrequently attributable largely to the twisting of the uterus. These symptoms may be both subjective as well as objective; there may, for instance, be more or less hematuria. Any participation of the urinary bladder in the twisting has not been observed, although GOFFE³ describes a twisting of the bladder toward the right and upward.

When a tumor springing from the pelvis without producing any particular symptoms during a rather long period of growth suddenly gives rise to acute symptoms then suspicion that a twisting of the pedicle has occurred arises. The severe acute or sub-acute symptoms which may be caused by the twisting of the pedicle of an ovarian tumor or of a pedunculated uterine myoma, or of the twisting of the axis of the uterus, such as ascites, peritonitis, septic infection, resemble each other so much in the various cases that, without previous accurate knowledge of the tumor, it may be impossible to make a correct diagnosis of the fundamental condition, because the differential signs between uterine myoma and ovarian cyst may be obliterated on account of disintegration in the interior of the myoma or on account of acute

peritonitis. The less acute the symptoms the more important, from a diagnostic standpoint, become the vesical disturbances, especially when the examination can exclude cystitis and compression of the bladder by tumor. In the case already referred to reported by SWITALSKI, a positive diagnosis of twisting of the axis of the uterus was made because the left border of the uterus was found by examination to point directly backward, and in addition there were present the acute symptoms of twisting of the pedicle of an ovarian tumor. Any spiral twisting of the cervix has not yet been made out in such case during vaginal examination, even in narcosis. Perhaps future diagnostic value may be gotten from palpation of the ovaries. In one of SCHULTZE's cases the finger in the rectum could demonstrate very plainly the fundus of the retroflexed uterus, but no ovary could be felt, and there was no pedicle to be demonstrated going from the cornu of the uterus to the tumor. At the operation the tumor was found to be a myoma of the uterus with a short pedicle which had twisted the uterus 180 degrees, and had brought the ovaries so far out of reach that they could be palpated from the rectum. When the tumor was removed the uterus and the ovaries assumed their normal position. The circumstance, therefore, that one or both ovaries can not be found in the space where they, according to the position of the uterus, should be expected to lie, may point to twisting of the axis of the uterus, especially in cases whose symptoms point in that direction. The palpation of the tubes and of the ovarian ligaments to the ovaries will help in further clearing up the conditions, but there will be many cases in which the presence of the tumor may interfere with the results ordinarily obtained by palpation.

SPLENIC ENLARGEMENTS.

In latter day practice making a physical examination of a patient is not looked upon by a careful physician as complete, especially in hospital work, without an attempt to palpate the spleen; and this procedure is becoming more and more common in view of the light often thrown upon a case by the detection of some abnormality in the splenic region. Such abnormality must of necessity be in the nature of an enlargement, for a spleen of normal size is not palpable below the free margin of the ribs. In the discussion, then, of diseases of this organ, we must deal first with enlargements; then we must decide whether these are enlargements of the spleen or of more or less contiguous structures; and, if of the spleen, are they tumors (in the strict technical sense of the term), or is the enlargement due to increase in the splenic pulp. Before a satisfactory conclusion can be reached, a strict inquiry into pathologic, previous and present histories must be made and there should be a thorough examination of the blood and urine.

² Schultze, *Loc. cit.*

³ American Journal of Obstetrics, 1895.

The normal organ is generally regarded as situated between the ninth and eleventh ribs, just posterior to the mid-axillary line. If there is universal enlargement of any degree, the dulness would be anterior to this line and the lower limit of the spleen would be below the costal border. It may then be taken as a fairly safe rule that any spleen is enlarged that can be felt below the free margin of the ribs. Given an enlargement in the splenic area, how are we to tell that it is the spleen? It must not be forgotten that an enlarged spleen, greatly enlarged, may reach as far forward as the median line and downward below the level of the umbilicus. The spleen moves with the movements of the diaphragm. If the examining hand be placed transversely across the abdomen, pressing the latter just below the enlargement, and the patient be asked to take a long breath, the edge of the mass, if it be the spleen, can be felt to "ride over" the hand with a decided shock. The examination can be greatly facilitated by having the patient flex his left leg, the physician manipulate from the patient's right, and with his left hand in the lower axillary region make strong pressure downward toward his right hand, which should be the one placed transversely across the abdomen. Another point of some value is the "flatness," if one may so express it, of the ordinary splenic enlargement. Usually a sharp edge is felt. Lastly, the normal splenic notch is as a rule very much in evidence in the pathologic condition.

The organ which first comes to mind, an enlargement of which might be confused with a similar condition as regards the spleen, is the left kidney. A renal enlargement of such a size as to occupy the position of the spleen (in addition to its own and the intervening space), would in almost every case be due to malignant disease (also hydronephrosis). A diagnosis would then rest upon the rapid growth, irregularity of the tumor, cachexia, age (sarcoma of the kidney usually occurs in young children), secondary deposits, examination of the urine and the absence of the special physical signs mentioned under splenic enlargement. We would next have to consider tumors of the pancreas, for new growths are the only lesions that would cause marked enlargement of this organ. Of the new growths carcinoma is the only one deserving of serious consideration: here the central situation, rapid growth, nodular character, and other signs of malignancy, the glycosuria and fatty stools not infrequently present, would be of material aid in the diagnosis. Tumors of the colon would have to be situated at the turn and be of great size to cause a suspicion that we were dealing with a splenic tumor. Such a tumor as it increased in size would be likely to bring about enteroptosis, the amount of intestinal prolapse being commensurate with the weight of the new mass, unless tight adhesions should have been formed to the contiguous structures, when there would be no displacement whatever. It would likely move with the diaphragmatic

movements, unless powerful adhesions were formed. One group of symptoms of importance would be, pronounced intestinal disorder, pain, tenesmus, hemorrhage, diarrhea alternating with constipation or even with intestinal obstruction. These tumors are also usually of a malignant character. Solid tumors developing from the bony framework, usually chondromata, would not cause much difficulty in diagnosis, nor would tumors of the abdominal walls. Other enlargements, such as floating kidney, hydronephrosis, tumors of the female organs of generation, localized peritoneal accumulations, enlarged retroperitoneal glands, may offer interesting puzzles for diagnosis, but the instances already mentioned are the most common.

Having satisfied ourselves that the enlargement is the spleen, we have next to discover the underlying cause. The size and consistency is of considerable value in determining this, especially the former. A spleen but slightly enlarged, one just palpable below the border of the ribs, is a most common condition and occurs with probably greatest frequency in the acute infectious diseases, especially typhoid, pneumonia, acute tuberculosis; in such cases the consistency is soft and the normal splenic shape well retained.

The disease of most interest to us as clinicians, as regards the splenic tumor present in the affection, the so-called "ague cake," is undoubtedly malaria. Why it is that one patient will have a spleen barely palpable while another of apparently equal physical condition, and with a coincident infection, will have an enlargement so great as to be dignified by the term "ague cake," still remains one of the malarial mysteries. Certain it is that this "ague cake," once formed, never entirely disappears, though some lessening in size may occur from the cicatricial contraction of the newly formed connective tissue. Thus, years after a malarial infection, we may discover a splenic tumor; the patient may have totally forgotten his malarial attack. The present diagnosis would then be a matter of some difficulty, for as can readily be seen, a history of chills and fever would be of paramount importance. The blood may have been free of any malarial stigmata for years. Of some value in a case of this sort is an enlargement of the liver, though never to a great size; even here, however, that same cicatricial contraction of newly formed connective tissue may have caused the liver to assume the proportions of a cirrhosis; indeed the existence of the hepatic malarial cirrhosis is admitted by most authorities on the subject. Gastric and intestinal disturbances are common in this condition, while a point of great importance if present, which it rarely is, is the brownish pigmentation of the skin, not more pronounced, as it is in Addison's disease, in any particular locations. When a spleen enlarges in an ordinary attack of quartan or tertian malaria, the tumor becomes readily manifest in less than a week, and the paroxysms of chill, fever and sweat, occurring at regular intervals.

together with the presence of the plasmodium in the blood, will quickly determine the causal factor in the enlargement.

The splenic tumor of leukemia offers even less difficulty; it is also often combined with enlargement of the liver. The splenic shape is retained, as is the normal notch. As regards size, in the spleno-myelogenous variety of the disease, it frequently extends as far forward as the middle line of the body, and downward below the level of the umbilicus. The surface is extremely hard and as a rule smooth. It might also be said that its surface possesses a pancake flatness. In the lymphatic form of leukemia the enlargement never becomes very great. The general symptoms, weakness, malaise, dyspnea, edema, pallor, hemorrhages (retina, nose, rectum, kidney) combined with the hematologic examination, anemia, leucocytosis varying from one to five hundred thousand, myelocytes (as high as 30 per cent. in the spleno-myelogenous form), lymphocytosis (as high as 90 per cent. in the lymphatic variety) would readily determine the diagnosis. Hodgkin's disease would not as a rule be difficult to distinguish, from its clinical resemblance to leukemia, but negative character of the blood. In this disease, too, while the spleen is never excessively enlarged, in fully one-half the cases the enlargement is nodular, due to lymphoid growth, so that the disease might more properly be reckoned under tumors of the spleen. Lymphoid growths in other organs, and especially the common glandular tumors, would also be of great aid here.

Amyloid disease affecting the spleen would result in a hard, firm, smooth, greatly enlarged organ, also a similar condition of the liver; the history would be that of long-continued suppuration, not infrequently an old tuberculosis which has become infected with pus germs, or syphilis. The presence of casts in the urine, answering to the amyloid reaction, would be a strong factor in the diagnosis. In children the spleen becomes more readily palpable from slight pathologic causes than in adults; thus it becomes enlarged in all the anemias, in congenital syphilis, and especially in rickets. The shape is retained. Tumors of the spleen are infrequent and with the exception of the lymphoid growths of Hodgkin's disease, need hardly be taken into consideration. The most important are gumma, tuberculosis, carcinoma, sarcoma, hydatids. After all is done and said, when one thinks of the great variety of splenic enlargements, and the greater number of other conditions for which it might be mistaken, he may well look upon the etiologic factor of tumor in this region as one of the most difficult problems in clinical medicine.

THE JOURNAL AND ITS FRIENDS.

When *Printer's Ink* was victimized by some forger who used the good name of the JOURNAL on a blank, how the Pharisees shouted to see the alleged slip

from the plain, straight orders on which advertisements are admitted! The ghoulis "I told you so," and the mother Caudle-like lectures which have been read to the JOURNAL would be amusing if they were not plain and manifest examples of ill will, spite and jealousy. One medical journalist alone had the good sense to write a letter here asking the JOURNAL if the statement published in *Printer's Ink* was correct. That gentleman was promptly informed that the circular had not been received in this office, and that, long before, the article in question was refused admission to the advertising columns of the JOURNAL. Had the other journals been true friends, they too, would have written to this office for information, before falling upon us tooth and nail. Let us see now how promptly they can disclaim the wrong they have done us. As we have printed a fac-simile of the document on which the patent medicine people put us in their list, perhaps they can point out the person who filled up the blank by recognizing the hand-writing.

THE JOURNAL SPECIAL TRAIN TO DENVER.

The JOURNAL SPECIAL TRAIN will leave the Union Depot, Adams and Canal Streets, Chicago, Saturday, June 4, at 11 P.M., via the Chicago, Burlington & Quincy Railroad, arriving in Denver Monday morning 7 A.M., in time for the meeting of the American Academy of Medicine, the American Medical Editors' Association and other medical organizations holding sessions on Monday.

Pay no attention to statements other than those announced in the JOURNAL. The reason for arranging for the stop-over on the return trip was owing to the fact that the Exposition at Omaha will be in much better condition then than now. Passengers from the East taking the JOURNAL SPECIAL at Chicago may have their stop-over arranged without extra cost.

The "Special" will run through. Tickets will be good for thirty days. The rate will be one fare and \$2 for the round trip, the most favorable rate yet granted the ASSOCIATION.

There is but one JOURNAL SPECIAL train, and that is managed solely in the ASSOCIATION interests. Personal and not ASSOCIATION interests have promoted most of the other "specials." Stand by the regular JOURNAL train, Chicago to Denver via the *Burlington* route.

CORRESPONDENCE.

Testimonial Corrected.

LOS ANGELES, CAL., May 18, 1898.

To the Editor:—In a forty page booklet entitled, "The Present Status of Diphtheria Antitoxin Serum," issued in large editions by H. K. Mulford & Co., of Philadelphia and Chicago, on page 31 appears a testimonial in which is a wilful change of name of the firm mentioned, which alleged testimonial reads as follows:

"California State Board of Health. The antitoxin used in

California is made in this country, and after considerable investigation and trials of the German and French preparations, we are giving our preference to the American production. . . The antitoxin now used by the Board is that of H. K. Mulford Company,¹ Philadelphia, Pa. The American product is put up in better form for transportation and handling, which is of itself an important item. The concentrated 'Extra Potent' (500 units to each c.c.) is the best.—J. H. Davisson, Los Angeles, Secretary California State Board of Health, in Report on Diphtheria Antitoxin."

Permit me to say that I was never secretary of the California State Board of Health, and in the only report which I made upon antitoxin while a member of the said Board, I did not have occasion to mention the product of the above named firm. I enclose said report (which was published in Transactions of California State Board, and is a part of the official records of the State), which tells entirely a different story. As a member of the AMERICAN MEDICAL ASSOCIATION since 1877, I dislike to be placed in a false light before my confrères to satisfy mercenary ends of any over-zealous firm. I am very truly,

J. H. DAVISSON, M.D.,
Ex-Pres. California State Board of Health.

ASSOCIATION NEWS.

Rates for the Denver Meeting.—The Committee on Transportation announce that the final decision of the New England roads and those of the Trunk Lines territory in the matter of rates for the Denver meeting, is for one full fare plus one-third full fare returning on the certificate plan. Tickets will be sold three days before the meeting, Sunday excepted, and the certificates must be presented at Denver properly filled out, not later than three days after the close of the meeting, when the return ticket will be sold for one third the cost of the regular fare. Tickets sold in the New England and Trunk Lines territory must be used for continuous passage, both going and returning over the same lines, no diverse route returning having been granted. The Central Traffic has granted one fare for the round trip plus \$4 for diverse route privilege. The Western Association has granted a one fare rate plus \$2 for diverse route privilege. Under this rating the cost of an individual trip will be, from New York to Denver and return, transportation, \$64.75, Pullman \$22.00, meals \$15.00 (estimated), making the total round trip \$101.75. From Philadelphia to Denver and return, transportation, \$62.45; Washington and Baltimore, \$60.45; Harrisburg, \$60.10. Pullman fare, round trip from Washington and Baltimore, \$22.00; Harrisburg, \$20.00. The Pennsylvania Railroad has offered to members living in the Trunk Line territory to run a special train for fifty or more persons, furnishing a combined baggage and smoking car, dining-car, sleeping-cars and observation-car, to be run through from Jersey City to Denver and return, provide transportation for the round trip, Pullman berth for each passenger, all meals in the dining car, both going and returning, the trip to be made without stop-over en route for the following: Round trip from New York, \$95; Philadelphia, \$93; Washington, \$91; Baltimore, \$91; Harrisburg, \$91, with proportionate rates for other stations. The route of the special train going and returning is to be via Pittsburg, St. Louis and the Missouri Pacific Railroad to Denver. The special train returning will, if desired, run over the Union Pacific Railroad from Denver to Omaha, arriving at about 7 A.M., and leaving at 9 P.M., thereby giving fourteen hours at Omaha. For this privilege an additional charge of \$4 will be made. The special train must leave New York June 1 at 2 P.M., arriving at Denver June 7, 6 A.M. Those desiring to travel by the special train should communicate with their local Pennsylvania agent, or with George W. Boyd, General Passenger Agent, Philadelphia, who will arrange for tickets

¹ The product used is that of another firm as shown by the report.—ED.

and Pullman space. The special train will not be run unless a total of at least fifty passengers are secured from the Trunk Lines territory and the New England States.

H. L. E. JOHNSON,
Chairman Committee Transportation.

Greater New York Special to Denver.—At the last meeting of the New York County Medical Association, a committee on transportation was appointed to arrange for a Greater New York special train to the Denver meeting of the AMERICAN MEDICAL ASSOCIATION. All physicians and their friends of New York and vicinity going to the meeting are specially invited to join the regular ASSOCIATION special train party. They will find it to their advantage both socially and financially. Those who have attended the National meetings at a great distance can attest the value of going in good company and in large numbers. They point out as of incalculable value the preliminary introductions, the personal contact, the social intercourse, the interchange of sentiment, opinion and experience, and finally, the opportune appreciation of the personality of the interested. Thus prepared, en route, one enters more fully into a keen appreciation of the entire work and enjoyment during the period of the meeting. With these advantages before him, who would go alone? The most satisfactory arrangements are being made and special information will be forwarded to all who communicate with the chairman or any member of the committee.

J. J. E. MAHER, Chairman, 34 West Twenty-fifth St.; A. Ernest Gallant, 60 West Fifty-sixth St.; F. H. Wiggin, 55 West Thirty-sixth St.; Louis Fischer, 187 Second Ave.; W. R. L. Dalton, 477 West One Hundred and Forty-fifth St.

Announcement.—The following arrangements have been made for the Denver meeting of the AMERICAN MEDICAL ASSOCIATION:

Section Dinners will be given June 7, at 7:30 P.M., and social entertainments will be given on other evenings during the week.

Ladies' headquarters will be at Unity Church, where they will be received by the wives of physicians of Denver. Arrangements have been effected for their entertainment during their visit, and committees will escort the visiting ladies to the various points of interest in Denver.

On Friday June 10, a complimentary excursion to Idaho Springs and around the loop will be given by the Colorado State Medical Society. At Idaho Springs, the ASSOCIATION will be entertained by the citizens.

On Saturday, a complimentary trip will be made to Colorado Springs under the auspices of the Committee of Arrangements. At Colorado Springs the ASSOCIATION will be entertained by the local physicians and citizens. Visits will be made to all points of interest in the vicinity. Arrangements will be made for trips to Pike's Peak and the celebrated mining camp of Cripple Creek at low rates of fare.

At a date to be determined, special trains for Glenwood Springs will leave Colorado Springs via The Denver and Rio Grande Railroad and the Colorado Midland Railroad. Tickets \$5.00, good going via one railroad and returning the other, and for ten days from date of issue.

The trip to Glenwood is one of the most attractive in Colorado, giving excursionists a view of some of the finest scenery in the Rocky Mountains, including Pike's Peak, Ute Pass, the Valley of the Arkansas, Hagerman Pass, Canons of the Roaring Fork and Prying Pan, Canons of the Grand and Eagle Rivers, Tennessee Pass and the Royal Gorge of the Arkansas and passing through the cities of Pueblo, Leadville, Canon City and Florence.

Special Hotel rates will be given by the Hotel Colorado and other Hotels of Glenwood Springs. The springs, baths and swimming pool will be free to the ASSOCIATION.

Special cars will be hauled on the Colorado Springs train and the Glenwood Springs Special, only when handed to the railroads with their full capacity.

Medical Librarians.—The following have been appointed a local committee on Medical libraries in connection with the meeting of the AMERICAN MEDICAL ASSOCIATION in Denver: Henry Sewall, W. P. Munn and C. D. Spivak. It is believed that this occasion will offer favorable opportunity for the perfection of the organization of the Association of Medical Libraries, which has already been projected. A conference of those interested in Medical Libraries will be held at the Brown Palace Hotel, Denver, at 4 P.M., Monday, June 6.

The Rush Monument Fund.—The representative members of the State and Territorial medical societies, acting as members of the Rush Monument Committee, in their several localities, are reminded that at the approaching meeting at Denver, Colo., reports will be expected from each of them as to the amounts contributed by their respective societies, in fulfillment of the pledges made at the annual meeting in Philadelphia a year ago. At this date, the secretary-treasurer, *pro tempore*, has not had transmitted to him one-sixth of one per centum of the sums so enthusiastically promised.

ALBERT L. GIBON, M. D., Chairman R. M. C.

GEORGE H. ROHÉ, M. D., Secretary-treasurer R. M. C.

Executive or Business Committee.—The first meeting of the Executive Committee of the AMERICAN MEDICAL ASSOCIATION will be held in the club room of the Brown Palace Hotel, Denver, Colo., Monday afternoon, June 6, at 5 o'clock. Subsequent meetings of the committee will be held at the same time and place each afternoon during the meeting of the ASSOCIATION, unless otherwise ordered by the committee. It is essential for the successful conduct of the ASSOCIATION that all the members attend the meetings of the committee. L. DUNCAN BULKLEY, M.D., Secretary.

Railroad Rates.—The Western Passenger Association, Chicago, formally announces the following rates for the Denver Meeting of THE AMERICAN MEDICAL ASSOCIATION, June 7-10, 1898:

Rate.—One regular first-class normal tariff (not temporarily) fare, plus \$2.00, for the round trip from Association territory to Denver, Colorado Springs and Pueblo, Colo., and return.

Dates of Sale.—Tickets to be sold from Eastern Committee territory, June 2, 4 and 5, and from Trans-Missouri territory, June 5 and 6, 1898.

Limits.—On going trip tickets to be good for continuous passage commencing on date of sale up to first Colorado common point en route; stop-over to be allowed on going trip at intermediate Colorado common points, but to arrive at destination not later than June 7, 1898. The return to be continuous passage beginning on date of execution by joint agent, with the provision that the return passage shall not commence earlier than June 12, nor later than July 6, 1898. Tickets may be executed for return at destination or either of the other Colorado common points en route. Purchaser to commence his continuous return passage return journey from point of execution.

Diverse Routes.—For this occasion tickets may read west of the Missouri River, going one route and returning another via any regularly authorized route via which regular short line one way rates are properly applicable.

Section Dinners.—The following Section Dinners will be given at the Denver meeting of the AMERICAN MEDICAL ASSOCIATION on Tuesday, June 7, at 7:30 P.M.:

Practice of Medicine, Metropole Hotel.
Surgery and Anatomy: Obstetrics and Diseases of Women; Ophthalmology, Brown Palace Hotel.
Laryngology, L'Imperiale Hotel.
Materia Medica, Pharmacy and Therapeutics; Cutaneous Medicine and Surgery, Windsor Hotel.
Diseases of Children, The Albany Hotel.
Neurology and Medical Jurisprudence, University Club.
Stomatology, St. James Hotel.

In order that satisfactory arrangements may be made for dinners, it is essential that all members who expect to be present notify the Chairman of Committee on Section Dinners as soon as possible and not later than June 4.

E. C. RIVERS, Chairman,
16th and Stout Sts., Denver Colo.

Hotels.—The following is a list of the principal hotels of Denver with the rates agreed upon for the meeting:

The Brown Palace Hotel, 17th Street and Broadway. Take 17th Street (red) car to Hotel. European plan, \$1.50 per day and upward.

The Windsor Hotel, 18th and Larimer Streets. Take 17th Street car to Larimer Street. American plan, \$2.00 per day; room with bath, \$2.50 per day.

The Albany, 17th and Stout Streets. Take 17th Street (red) car to Hotel. American plan, \$2.00 to \$3.50 per day.

The Markham Hotel, 17th and Lawrence Streets. Take 17th Street car to Hotel. European plan, \$1.00 per day and upward.

All reservations at the Albany and Markham must be for the full term of the Meeting, and be paid for whether occupied or not unless canceled ten days in advance. They reserve the right to place persons occupying a room alone in a single room.

The New St. James Hotel, Curtis near 16th Street. Take 17th Street (blue) car to Hotel. American plan, \$2.00 to \$3.50 per day.

L'Imperiale, 14th Street and Court Place. Take Colfax Avenue car to Court Place. American plan, \$2.00 to \$3.00 per day.

Metropole Hotel, Broadway near 17th Street. Take 17th Street (red) car to Broadway. European plan, \$1.00 to \$2.00 per day. \$1.00 rooms, \$1.50 if occupied by two persons. No reservations made.

The Oxford Hotel, 17th and Wazee Streets. Two blocks above depot. European plan, \$1.00 to \$3.00 per day. An extra charge for two persons in one room.

The American House, 16th and Blake Streets. Take 16th Street car to Blake Street. American plan, \$2.00 per day.

The above hotels make no extra charge for reservations or for persons occupying a room alone except as stated.

The Hotel Broadway, Cheyenne Street and Broadway. Take Colfax Avenue car to Cheyenne Street. American plan, \$1.25 to \$1.50 per day.

The Vallejo, 1420 Logan Avenue. Take Colfax Avenue car to Logan Avenue. American plan, \$2.00 per day and upward.

The Devonshire, 14th and Logan Avenues. Take Colfax Avenue car to Logan Avenue. American plan, \$1.50 per day and upward.

The Albert, 17th and Welton Streets. Take 17th Street (red) car to hotel. European plan, \$1.00 to \$1.50 per day.

The Aldine, 1013 Seventeenth Avenue. Take 17th Street (red) car to hotel. American plan, \$1.25 per day.

The Richelieu, 1727 Tremont Street. Take 17th Street (red) car to Tremont Street. European plan, \$0.50 to \$1.00 per day.

The Earl, 1430 Tremont Street. Take Colfax Avenue car to Tremont Street. American plan, \$1.50 to \$2.00 per day.

Glenarm Hotel, Glenarm and 15th Streets. Take Colfax Avenue car to hotel. European plan, \$1.00 per day and upward.

The Bonaventure, 18th and Glenarm Streets. Take 17th Street (red) car to Glenarm Street. European plan, \$0.50 to \$1.50 per day.

The Drexel, 17th and Glenarm Streets. Take 17th Street (red) car to hotel. European plan, .75 to \$1.50 per day.

These hotels make small extra charges for two persons occupying same room. No charge for reservation.

Applications for rooms should be made to the hotels direct. For special information apply to ROBERT LEVY, M.D., Chairman Sub-Committee on Hotels, California Building, Denver, Colo.

J. W. GRAHAM, M.D., Chairman.
W. A. JAYNE, M.D., Secretary.

SOCIETY NEWS.

Æsculapian Society.—The program of the semi-annual meeting of the Æsculapian Society of the Wabash Valley, to be held in Robinson, Ill., May 26, has been received.

Illinois State Medical Society.—The sessions closed May 19 and Cairo was chosen as next place of meeting. The officers chosen are as follows: President, T. J. Pitner, Jacksonville; first

vice president, H. N. Moyer, Chicago; second vice-president, J. T. McAnally, Carbondale; treasurer, George N. Kreider, Springfield.

Iowa State Medical Society.—Cedar Rapids was chosen as the place of the next meeting, 1899, and the following officers were elected at the recent meeting of the society: President, H. B. Young of Burlington; vice-presidents, J. T. Priestley of Des Moines, D. C. Brockman of Ottumwa; treasurer, G. R. Skinner of Cedar Rapids; secretary, J. W. Cokenower of Des Moines; new trustees, Calvin Snook of Fairfield, W. D. Middleton of Davenport.

Arkansas State Medical Association.—At the recent meeting of this association, held at Eureka, Springs, the following officers were elected: President, J. W. Hayes, Eureka Springs; secretary, Frank Vinsonhale, Little Rock; treasurer, Dr. Thompson, Pine Bluff; chairman section on practice of medicine, Dr. Bargile, Bentonville; section on surgery, Dr. Shinault, Helena; section on obstetrics, J. B. Bolton, Eureka Springs. The next meeting will be held at Little Rock.

Indiana State Medical Society.—The forty-ninth annual meeting of this society was held at Lafayette, Ind., May 4 to 6. The first session was occupied with a report of the Indiana State Pediatric Society, which is an auxiliary to the general society, on "What Are the Effects of Disease Upon the Developing Mind of Children?" It was discussed as follows: "Diseases of the Nervous System," P. G. Barcus of Crawfordville; "Diseases of the Respiratory and Circulatory Organs," Don Kennedy of Homer; "Diseases of the Digestive Organs," Louis Burkhardt of Indianapolis; "Diseases of the Excretory Organs," A. W. Brayton of Indianapolis; "Infectious and Hereditary Diseases," John A. Lambert of Indianapolis; "Conditions Dependent on Defective Hygiene," W. J. Purkiser of Salem. One of the features of the convention was the exhibit made in Carlyle hall by the manufacturers of surgical instruments and medical appliances of every description. The next meeting will be held in Indianapolis, June 6 and 7, when the fiftieth anniversary will be celebrated. J. C. Smith of Rushville was elected president, and T. C. Heath of Indianapolis, secretary.

Minnesota State Society. Section on the Practice of Medicine. Chairman, Charles Lyman Greene, St. Paul. The program includes the following:

- "Bicycle Therapeutics," by C. H. Hunter, Minneapolis.
- "Diabetes Mellitus," by J. G. Cross, Rochester.
- "Adenoids in their Relation to General Disease," by Albert C. Heath, St. Paul.
- "Points in the Differential Diagnosis of Ascites," by Arthur R. Edwards, Chicago.
- "The Treatment of Pneumonia by Cold," by H. Wernicke Gentles, Chicago.
- "Two Cases of Appendicitis Treated by Calomel and High Injections," by P. A. Walling, Park Rapids.
- "Appendicitis from the Standpoint of the General Practitioner," by Theo. L. Hatch, Owatonna.
- "Lead Poisoning from an Unusual Source," by Franklin A. Dodge, LaSueur.
- "Subcutaneous Emphysema occurring During the act of Vomiting," by A. W. Dunning, St. Paul.
- "Induced Abortion; Sepsis, Anura lasting Eleven Days, Death," by Andrew Henderson, St. Paul.
- "Presentation of Case of Valvular Heart Disease of Unusual Interest," by T. A. Conley, Cannon Falls.
- a. "Laundry's Paralysis, Complete Respiratory Paralysis—Life Maintained for Forty-two days by Artificial Respiration"; b. "Splenomedullary Leukemia"; c. "Pernicious Anemia," by Charles Lyman Greene, St. Paul.
- "Leukemia," by Hugh F. McCaughy, Winona.
- "Treatment of Tuberculosis," by C. A. Haas, St. Paul.
- "Presentation of Case of Myxedema," by Walter Ramsey, St. Paul.
- "A Staggering Coincidence," by F. W. Epley, New Richmond.
- "Treatment of Pneumonia by Pilocarpin," by E. J. Davis, Mankato.

"Widal's Test in Diagnosis of Typhoid Fever," by Louis B. Wilson, Minneapolis.

"Diazo-reaction in Diagnosis of Typhoid Fever," by J. P. Barber, Minneapolis.

PUBLIC HEALTH.

An international Congress for the protection of abandoned children is to be held at Antwerp in June, which includes in its scope the protection of child beggars, vagabonds and liberated prisoners.

Bicycles belonging to physicians have the right of way in the streets of Aueburg. The bicycle carries a red cross shield, so that the rider's profession is known to all, and much good has already resulted from the custom, it is stated, in securing prompter assistance in accident emergencies.

To Detect Adulteration of Coarse Flours with Saw-dust moisten with an alcoholic solution of phloroglucin acidified with phosphoric acid. Warm a little and the particles of wood will become a bright carmine, while the fragments of the cellulose of the grain and the starch are not affected by the stain.—*Presse Méd.*, April 13.

Pure Albumin as Cheap Food for the Masses.—Professor Finkler appeals to hygienists in general to test and help introduce the new tasteless, inexpensive preparation of pure albumin, which, added to vegetable soups, meat extracts, or any dish, enhances its nutritive properties and in the most concentrated, easily digestible form furnishes a valuable food at less than half the expense of meat. It is obtained from almost all kinds of vegetable and animal substances, in the form of a dry powder, which keeps indefinitely and accomplishes all that an albumin can in building up strength and tissue, as he has thoroughly demonstrated. He calls it Tropon; further details in the *Deut. Med. Woch.*, of April 28.

Prophylaxis of Tuberculosis.—The committee appointed by the Paris Académie de Médecine for the study of this subject, has been made permanent "to encourage and co-ordinate efforts of protection against the invasion of the tubercle bacillus." The committee insist upon: 1, Pocket or apartment cuspidors containing a little 5 per cent. phenicated solution, colored, or at least a little water; 2, the substitution of wiping with a damp cloth for sweeping; 3, having milk boiled before drinking, whatever source it comes from. They recommend temporary retirement from the army at the first indications of tuberculosis, and permanent dismissal as soon as the bacilli are found in the sputa. Also the isolation of tuberculous patients in separate wards or pavilions until special sanatoria can be erected; antiseptics throughout; remodeling the floors and suppressing of sweeping; improving the attendant service by higher salaries, more careful recruiting and provisions for pensions. Also the creation of a corps of sanitary nurses. In regard to meat from tuberculous animals, confiscation and total destruction are only necessary in the rare cases of generalized and hectic tuberculosis. Animals found by the tuberculin test to be slightly tuberculous and therefore still harmless, should be sold at once to the slaughter house before the disease progresses or infects others.

Serum Therapeutics and Prophylaxis of Yellow Fever. Sanarelli reports very encouraging results with his serum in an epidemic at S. Carlos do Pinhal. Twenty-two patients were treated with it, with six deaths; a mortality of 27 per cent., instead of the average 45, and this merely the first tests of the serum, determining doses, concentrations, etc., step by step, and administering it to several patients evidently beyond all help before being seen. In one case abrupt convalescence followed a single injection the second day. He considers the serum bactericidal rather than antitoxic in its effects, and obtained most striking results with intravenous injections of large doses. In

three of the fatal cases the bacillus *icteroides* was isolated from the blood during the agonic period, by using the serum reaction method. He finds the horse best adapted to the production of the serum. He is especially encouraged by the results at the prison where yellow fever attacked a prisoner and two guards, all early fatal cases, but prompt prophylactic injections arrested the disease at once and no further case occurred. He adds: "the instantaneous suppression of this focus of infection was obtained in spite of the most unfavorable conditions and the lack of active serum, the horse serum being all exhausted and nothing left but the much weaker beef serum. The persons who received the injections were also either mostly unacclimated strangers or in wretched physiologic conditions owing to the depressing and extremely unhygienic surroundings, and thus exceptionally predisposed to the disease." His report is published in full in *O Brazil Médico* of April 1 and 8. He vouches strongly for the absolutely harmlessness of the prophylactic injections from experience on himself as well as on others. His facilities were limited, as he only had a few animals at his disposal.

NECROLOGY.

EDWARD H. DORLAND, M.D., Chicago, President of the Lakeside Hospital, died at his home May 14, aged 56 years. He was a graduate of the Miami Medical School, Cincinnati.

THADDEUS POMEROY SEELEY, M.D., Chicago, died of pneumonia at his residence, May 16, aged 67 years. Dr. Seeley was surgeon of the Sixteenth Michigan Volunteers during the Civil War, was with McClellan in his Virginia campaign and for some time a prisoner at Libby. He was graduated in medicine from the University of Michigan in 1856.

JOHN M. GALT, M.D., Baltimore, Md., May 13, aged 87 years, one of the early graduates of the Maryland University School of Medicine.—James J. McAvoy, M.D., Waterbury, Conn., May 11.—A. B. McGinnis, M.D., Guyandotte, W. Va., May 11, aged 79 years.—William T. Walker, M.D., Lynchburg, Va., May 13.—John Sloan, M.D., New Albany, Ind., April 13, aged 80 years.

DEATHS ABROAD.—Dr. Humbert Mollière, Physician to the Lyons Hospitals, and author of numerous monographs on the history of medicine and the medical antiquities of Lyons, aged 53 years.—Jacob Schütz of Prague, author of several monographs, aged 82 years.—Dr. Eduardo Periera Pimenta, Professor of Surgery in the Eschola Medico-Cirurgica, of Oporto, aged 60 years.—Dr. Georg Dragendorff, formerly Professor of Pharmacy and Toxicology in the University of Dorpat, and author of works on medicinal plants, poisons, etc., aged 62 years.—Dr. C. Barzilai, some time Professor in the University of Padua, and physician to the military hospital at Venice.—G. Guelpa, who introduced hydrotherapy into Italy, aged 81 years.—Dr. Lopez Alonso, Professor in the Medical Faculty of the University of Salamanca, and a well known writer, aged 44 years.—Dr. Zancanol, physician to the Greek Hospital, Alexandria.

ISAAC N. QUIMBY, M. D., (*vide JOURNAL*, p. 1191). The following resolutions were recently passed by the American Association for the Study and Cure of Inebriety:

WHEREAS, Almighty God in his inscrutable providence and wisdom has removed from our midst our friend and collaborer, Dr. Isaac N. Quimby; therefore,

Resolved, That while we bow with humble submission to this dispensation of the Divine Will, we mourn in common with the family and friends of the deceased the irreparable loss that all have sustained.

Resolved, That in the death of our friend and associate, there has passed from our number and the sphere of active duty, one, who in his life by his professional attainments and the honest straight-forward and fearless adherence to the principles he professed, exemplified the highest type of Christian manhood.

Resolved, That in the death of Dr. Quimby the community in which he dwelt and the State at large have lost a good and upright citizen; the medical profession, one who advanced it by his high attainments and by his long practical and useful life; and his family and friends and this Association, one who, from a social, moral and intellectual stand-point, was their stay and support.

Resolved, That these resolutions be engrossed and sent to the family and friends of the deceased and that a copy be sent to the *JOURNAL* and also published in the *Journal* of this Association on behalf of the American Association for the Study and Cure of Inebriety.

BOOK NOTICES.

Epidemic Cerebro-spinal Meningitis, and Its Relations to Other Forms of Meningitis. A report of the State Board of Health of Massachusetts, by Dr. W. T. COUNCILMAN, Dr. F. B. MALORY and Dr. J. H. WRIGHT. Boston: Wright & Potter Printing Company, State Printers, 1898.

This report was an investigation undertaken with a view of clearing up certain obscure points in general etiology and pathology of the disease, and is based on the epidemic which prevailed in Massachusetts in 1897.

The preceding literature has been well studied and this report may be considered in itself a complete monograph on etiology and pathology. As to diagnosis the authors say: "The surest method of diagnosis, and one which should always be carried out when possible, is by lumbar puncture. The method is easy, and experience has shown it to be devoid of danger. If properly carried out in the early stages of disease, which is the time when there is more difficulty in diagnosis, it is almost conclusive. It certainly deserves to be ranked as a method of diagnosis with the examination of the sputum. If the patient has meningitis, a more or less cloudy fluid will be withdrawn: if it is the epidemic form, diplococci will be found in it either on microscopic examination or in cultures. It is of the greatest importance in the study of the epidemics that this method of diagnosis should be carried out, especially in the sporadic cases. In some of the chronic cases, if seen late, there may be a question of diagnosis between meningitis and typhoid fever."

"The essential seat of the disease is in the meninges of the brain and cord. How the organism gains access to the meninges is not actually known. It is possible that the nose forms the portal of entry, the organism passing from the nose to the meninges by means of the lymphatics connecting this with the subdural spaces. In a number of cases organs identical with it on microscopic examination have been found in the nose, together with the evidences of slight acute inflammation."

"The lesions in the meninges are confined to the pia-arachnoid, in which an acute purulent inflammation is produced. From the meninges the process extends into the brain substance. Lesions are found not only in the cortex but in the depth of the tissue and in the ventricles. These lesions consist in part of purulent infiltration of the tissue both around the vessels and elsewhere, together with proliferative changes in the neuroglia and the degenerative changes in the ganglion cells and nerve fibers. The cord is always affected, and to a greater extent than in any of the other forms of meningitis. The organisms are found in considerable number in the most acute cases. In the more chronic cases they may be missed."

The fluid should be obtained in the early stage as, if the spinal puncture be made late in the disease, the result may be negative.

The Diseases of the Stomach. By WILLIAM W. VAN VALZAH, A.M., M.D., and J. DOUGLAS NISBET, A.B., M.D. Philadelphia: W. B. Saunders, 1898. Pp. 674. Price \$3.50.

This book is intended primarily as a guide for the student

and practicing physician. There is no preface and the introductory is brief.

The authors have endeavored to make this a simple, clear, practicable, complete and useful book of information, and have not burdened it with history nor bibliography.

The aim seems to have been to have a discussion of the essentials of the subject without superfluity. The book is divided into six sections, in which the first is the introductory and classifications; the second the treatment and diagnosis, and diagnostic methods; the third is devoted to general medication. These three sections constitute the general or first part of the book.

The fourth section treats of the dynamic diseases of the stomach. The fifth section treats of the anatomic diseases of the stomach. The sixth section treats of the vicious circles of the stomach, that is, the stomach in the causation of diseases of other organs.

The arrangement is admirable and the teaching sound, and the publisher has done his work well. The work might be improved by adding more illustrations, but the most hypercritical would find but little fault with the text.

Essays on Bacteriology and the Relation to the Progress of Medicine. By THEODORE POTTER, A.M., M.D. Indianapolis: *Indiana Medical Journal Publishing Company*. Pp. 161. 1898.

This publication has its origin in a series of papers upon the progress of bacteriology, presented by request of the Indiana State Medical Society, between the years 1890 and 1897.

It is very pleasantly written and constitutes a valuable addition to the literature of the period in which the truths of bacteriology are forcing themselves upon the attention of the rank and file of the medical profession. They are argumentative, interesting and logical.

PRACTICAL NOTES.

Diphtheria Serum in Scarlet Fever. Hutinel reports a death, and Montoux arthralgia and delirium after an injection of the serum in a child whose throat contained the Loeffler bacillus, strepto- and staphylococcus during the initial stage of scarlet fever.—*Presse Méd.*, April 23.

Indications for Operating Goiter (Kocher).—Thyroidectomy is indicated for: 1, malignant tumors in the thyroid gland; 2, acute and chronic thyroiditis; 3, parenchymatous goiter (general hypertrophy); 4, polycystic goiters; 5, goiters with multiple nuclei. It is counter-indicated by absence of normal tissue on the opposite side. Strumectomy or intraglandular enucleation is indicated for: 1, unilocular cystic goiters; 2, isolated nuclei located in normal tissue if they allow rapid removal without much hemorrhage; otherwise, thyroidectomy; 3, large nuclei in immovable goiters. These indications do not apply to exophthalmic goiter, which Kocher has treated with good results by ligating the three thyroid arteries and later the fourth. Double section of the sympathetic is still *sub judice*.—*Rev. de Chir.*, April 10.

Maternal Thyroid Treatment of Goiter in the Newly Born.—At a recent meeting of the Paris Academy of Medicine, Dr. Mossé read an account of a woman, aged 29 years, who was the subject of a goiter accompanied with feeble-mindedness, but without symptoms of myxedema. Her general health was good. Her child, who was three months old and breast fed, had a large bilobed goiter, was very puny and sickly but had no signs of myxedema. The mother was put upon thyroid treatment, and took daily a quantity of thyroid extract corresponding to 1.5 grams of thyroid gland. At the expiration of one and a half months the mother's goiter had diminished in size, but a still more marked result was obvious in the child, whose general health was excellent. After the lapse of a slightly shorter period of treatment the goiter in the infant had completely dis-

appeared and it was making good progress, while the goiter in the mother continued to decrease. This is the first recorded case of the influence of thyroid treatment being transmitted from mother to child in the milk.

Captol; a New Antiseborrheic.—Eichhoff in the *Deutsche Med. Woch.*, recommends captol, a condensation product of tannin and chloral, in seborrhea capitis and its complications, such as itching, scale formation and thinning of the hair. Captol has more rapid and definite effects than a mixture of the two drugs from which it is made, and is entirely harmless and unirritating. It forms a dark brown, hygroscopic powder which dissolves with difficulty in cold water, but more easily in a mixture of warm water and alcohol, is not affected by acids, but is decomposed by alkalis and turns dark. Eichhoff employs it in a 1 to 2 per cent. alcoholic solution, and asserts that in every case in which he has employed it his results have been wonderfully good. In eight to fourteen days the scales have disappeared from the scalp, the hypersecretion of the sebaceous glands has ceased, and the falling out of the hair has stopped. He employs the preparation called "spiritus captoli compositus," which has the following formula:

Captol,	
Chloral hydrate,	
Acid. tartaric	1.0 gm.
Ol. ricini	0.5
Spirit. vin. (65 per cent.)	100.0
Essent. flor. æth	9.5

Velander's Pillow-Slip Method of Mercurial Inunction.—Dr. R. Hogner describes this new procedure of the Stockholm professor, Dr. E. Velander, for the application of mercurial ointment. He considers it to be practical, effective, convenient, and clean. Velander was convinced some years ago that the mercury in an ointment is absorbed after being vaporized. He has, therefore, given up spreading the ointment upon the skin, and spreads it instead upon the inside of a small pillow-case, which is hung upon succeeding days alternately on the back and on the chest. It is kept in position by ribbons over the shoulders and around the waist. The pillow-case is made of cheap cotton cloth, and one of the external faces is smeared with the ointment. It is then inverted so as to bring the ointment on its inner surface, and is placed in position so that the layer of cloth upon which the ointment is spread is in direct contact with the body, while its unsmeared side protects the clothing. Every night fresh ointment is spread over the old without removing this, and at the end of ten days the pillow-case is thrown away and a new one is prepared. Baths should be taken twice a week, and the skin of the chest and back washed every night. The quantity of ointment used daily is 6 grams (90 grains). The effect of the treatment is very rapid, as more mercury can in this manner be absorbed with fewer unpleasant effects, such as stomatitis, etc., than when it is otherwise administered.—*Boston Medical and Surgical Journal*, March 31.

Surgical Treatment of Profuse Hemorrhage in Ulceration of the Stomach.—Dieulafoy has made to the Paris Academy an important communication on the above subject. One of his patients was seized with a very profuse hemorrhage and lost, in the course of thirty hours, between four and five liters of blood. A gastric ulcer was suspected, but at the postmortem examination there was found not the ordinary circular ulcer but a general ulcerated condition, though of a very superior nature. Another patient, aged 22 years, was also suddenly seized with hematemesis and promptly admitted to the hospital, where Czain performed laparotomy. Upon opening the stomach he found not an ordinary gastric ulcer but a superficially ulcerated patch the size of a penny. He pulled up the ulcerated mucous membrane into a fold, ligatured it, and the patient recovered perfectly. Altogether, Dieulafoy is aware of seven cases of this kind of ulceration. It is well known that besides

the simple ulcer described by Cruveilhier there may exist in the stomach a condition of very superficial loss of the substance of its walls, which is the initial phase of an ulcer and which may be followed by the gravest consequences. There is often no suspicion of anything being amiss until the occurrence of a sudden and profuse hemorrhage. Any patient who vomits half a liter of blood at one time, especially if the hemorrhage returns within twenty-four hours, will surely die if not operated upon without a moment's delay. If the surgeon does not find an ordinary ulcer he will find a superficially ulcerated patch and should by all means attempt to ligature this bleeding region. —*London Lancet*.

MISCELLANY.

Rush Monument Fund.—At the recent meeting of the Illinois State Medical Society, Galesburg, it was voted to contribute \$2000 toward the Rush Monument Fund.

Netley Army Hospital, England.—Queen Victoria shows her great interest in the wounded soldiers of her forces by providing ample supplies of artificial limbs and the best description of invalid couches at this hospital.

State Board of Examinations.—The State of Montana should be added to the list published in the *JOURNAL* of March 26, p. 742, as requiring all medical graduates to stand an examination before being permitted to practice in the State.

The Roentgen Rays and the Blind.—Out of 204 young blind persons, nine (all with peripheral lesions and a vague conception of light) were able to perceive the rays from a powerful Crookes' tube enveloped in a black cloth. Two felt the rays as pain. —*Jour. d'Hygiène*, April 14.

A Close Connection Between Epilepsy and the Magnetism of the Earth has been observed by Sokolow during two years study of twenty-six epileptics, the maximum of the magnetic currents corresponding to the minimum of the attacks. *St. Petersburg Med. Woch.*, April 23.

Ozone on Tap.—We can now have the air in our houses to suit all hygienic requirements, sterilize our drinking water, our food, etc., with an ample regulated supply of ozone, generated by a new ozonator which has rendered ozone a marketable commodity. —*Rev. Méd.*, April 27.

The Protective Action of the Organs Against Strychnin is shown by an interesting series of experiments by H. Roger, described in the *Presse Méd.* of April 24. The liver stands at the head in this respect, but other organs, the lungs, the intestinal epithelium, etc., neutralize the poison to a remarkable extent. This antitoxic action of the lungs is to be further investigated.

The Chicago Eye, Ear, Nose and Throat College, 67 Wabash Ave., at the end of its first year found its quarters too small to accommodate its students, and the board of directors secured the rooms adjoining, on the north, thereby increasing the floor space about three times. Double the present number can hereafter be accommodated. In its new quarters the college will be well equipped.

Trauma and Sarcoma.—In the *Annals of Surgery* for March Coley writes on "The Influence of Injury Upon the Development of Sarcoma." In 170 cases of sarcoma he reports 27 per cent. giving a history of trauma. He believes that the clinical evidence points very strongly toward a specific infection as a cause for sarcoma, the analogy between sarcoma and diseases of infectious origin being most striking, *e. g.*, the analogy, long observed, between sarcoma and tuberculosis.

"Condense, and Again I Say Unto You, Condense."—Virchow's *Archiv* enters upon its 151st volume with an urgent appeal to contributors to curtail the length of their communications, thus rendering them proportionately more valuable in every

respect. The vast quantity of MS. in our waiting list emphasizes the fact that Germany is not the only country where this wholesome rule is forgotten.

The Klondiker as a Risk.—In the *Medical Examiner* for March Abbott considers this subject. He believes that smallpox, typhoid fever, consumption, acute lung diseases, scurvy and violence may be counted on as being unusually destructive, sooner or later, to the Klondiker, while the favorable side is the average age of the adventurer, 20 to 45 years, a healthy period of life. He concludes that no insurance company can afford to take risks among Klondikers, nor allow its insured to make long sojourns in the Yukon country.

Acute Leucemia in Childhood.—In *Archives of Pediatrics* for May, Morse reports a case of acute leucemia in childhood, and concludes from his own and the seven other cases he was able to find reported, that there is no evident general etiologic cause, the disease sometimes beginning with typic leucemic manifestations and at others with general indefinite constitutional symptoms which, in the course of days or weeks, develop into the characteristic picture of leucemia. The course in children is not different from that in adults, and in both it is generally of the lymphatic type. In children acute leucemia is always fatal.

In Contemplated Nephrectomy, Edebohls (*Annals of Surgery*, April) advocates "incision down upon, delivery and examination of the fellow of the kidney to be removed, previous to completing an otherwise indicated nephrectomy." He claims priority in this and has carried it out in several cases. While the presence of a second kidney is determinable by other aids, *e. g.*, examination of the urine, palpation of the kidney, cystoscopy, catheterization of the ureters, skiagraphy, the fluoroscope, he believes exploratory incision to be the only method giving completely satisfactory information regarding the exact condition of the other kidney, and that should be the rule in every contemplated nephrectomy where the surgeon is not absolutely certain of the presence and condition of the other kidney.

Dancing Girls Physicians in the Philippines.—According to the *Crónica de Ciencias Med. de Filipinas*, there are a number of native young women on the island who practice the healing art at Deweyville. When one is summoned to a patient she appears with a crown, large fan and a small cane and inquires the seat of the pain. This she touches with the cane and proceeds to fan away the bad spirit causing the disease. She then orders a pig to be killed and the attendants rub the patient vigorously with the blood while she dances, making contortions and grimaces to frighten away the bad spirit. The meat of the pig is cooked and eaten by the crowd, the "physician" receiving the lion's share, and the same process is repeated day after day until the patient dies or his provisions are exhausted. The natives of the Island of Luzon treat diseases accompanied with pain by burning a series of holes around the seat of the pain with a burning stick from the *Ophelia chirata* L. They sometimes make a hundred applications on a child with convulsions. —*Journal d'Hygiène*, April 28.

Intraperitoneal Operations.—Brothers (*Medical Record*, April 30) gives some reflections on fifty intraperitoneal operations. Of the fifty, six cases were lost, three being moribund on reaching the operating table. He believes it one's duty to resort to the knife even when there is the least glimmer of hope for the patient, but that the surgeon has no right to remove the uterus because it is the seat of a chronic catarrh, even though obliged to remove both tubes and ovaries. There may be more justification for removing the uterus at the same time, on the plea of better drainage per vaginam, in cases of bilateral purulent infiltration of the adnexa, but even here he believes, with care, the pus sacs can be removed from above

without molesting the uterus and with no greater risk to life than when exsection of uterus and adnexa is done from below. He finds that a small percentage of extra-uterine pregnancies terminates in spontaneous recovery. When the diagnosis of early ectopic gestation is made, with symptoms pointing to impending rupture, the choice is between immediate laparotomy or intelligent delay with unremitting supervision. Where the latter can not be assured, operation should be done at once. He protests against ventral fixation in cases of uncomplicated mobile retroflexed uteri.

Resection of the Cervical Sympathetic.—Jonnesco has gradually extended this operation until it now includes the total and bilateral resection of the entire cervical sympathetic chain with all its vaso-constricting fibers for the encephalic vessels, which puts an end to the encephalic anemia. He has operated on thirty-five epileptics and reports the first fifteen as, five cured for a year and a half; four from nine months to a year; four much improved and two with negative results. The same operation applied to exophthalmic goiter, three cases, has given three successes (one nine months, the others five to one and a half months). Two cases operated on twenty months ago by extirpation of the two first ganglia and the intermediate cord have been perfectly cured to date. Six very severe cases of glaucoma were operated on by resection of the cervical ganglion. Three were remarkably benefited; previous double iridectomy had been ineffectual. Combemale also reports another case of exophthalmic goiter relieved by sympathicotomy. The exorbitism subsided immediately and the cardiac beat fell from 200 to 100 by the end of the week, with disappearance of the pain. The goiter was not affected as the operation probably only influences the toxic secretion of the thyroid, not the normal colloid secretion.—*Presse Méd.*, April 20.

Dressing for Fractured Clavicle.—Henson recently presented before the Richmond Academy of Medicine an improved method of treating fracture of the clavicle. He says that the strip, in the Sayre method, which passes from the sound shoulder underneath the opposite elbow and back again, does its work well when first applied, but is almost certain to slip and in warm weather very quickly; is apt to roll up on the shoulder and become cord-like, and is altogether very uncomfortable. In place of this strip he has, out of denim, unbleached jeans or other very stout cloth, a shoulder-cap fashioned for the sound shoulder. On this he has two extensions or tails, one opposite the other. This must be made to fit the whole shoulder and the upper part of the chest just below the axilla snugly, and so an armhole is necessary, which also serves to prevent slipping. There should be almost twice as much of the cap upon the shoulder as below the axilla. The posterior extension is directed across the back along a line drawn from the shoulder supporting the cap obliquely toward the opposite elbow, should reach a little beyond the median line and may be pointed. The anterior tail has the same course across the front of the chest, reaching as far as the opposite nipple; its end should be from one and one-half to two and one-half inches in width, according to the size of the patient, and upon its under surface a pocket is made, reaching from near its tip upward and outward quite to the top of the shoulder and just wide enough to accommodate the patient's hand. With tension made upon both extensions at the same time, in the line of their direction, the cap should bear equal pressure upon the shoulder and chest. To each extension he attaches a buckle. Another strip of the same kind of cloth is taken, narrow, oblong, sufficiently wide to accommodate the elbow, and long enough to reach from the middle of the arm to the middle of the forearm, when extended, and to each end of this a tape is attached. As to application, first the horizontal adhesive strip is applied, just as in the Sayre method, then the shoulder-cap is fitted upon the sound shoulder. Then into the pocket of the front extension, intro-

duce the hand of the injured limb, after carrying the forearm up across the front of the chest. Buttons may be used in place of the buckles.—*Richmond Journal of Practice*, April.

Spanish Army Losses in Cuba.—Between March 1, 1895, and March 1, 1897, Spain sent to Cuba 10 generals, 615 field and 6222 subaltern officers and 180,435 soldiers. To these must be added the 12,000 officers and men forming the regular Cuban establishment at the outbreak of the insurrection, making a total of nearly 200,000. Of these, 1 general, 7 field and 53 subaltern officers and 1314 men were killed in battle, 1 general, 6 field officers and 55 subaltern officers and 704 men died of wounds, while 463 officers and 8164 men were wounded and presumably recovered. The losses caused by the enemy are then small, being but little more than 5 per cent. of the total present for duty. The case is altered, however, in the matter of disease; 318 officers and 13,000 men died of yellow fever, while 127 officers and about 40,000 men succumbed to other maladies. A writer in the *Revue Scientifique* of October 16, 1897, gives the following rates of loss per thousand: Killed or died of wounds, 10.7; died of yellow fever, 66.0; died of other diseases, 201.3; sent home (sick and wounded), 143.0; as all the sick and wounded, however, have not been sent back to Spain, the number of these left behind must be taken into account in estimating the total losses of the Spaniards. While this number can not be accurately determined, yet there is reason for believing that it can not fall short of 20,000. Accepting this estimate, we have a total rate of loss of 521 per thousand for the two years considered; or, of the 200,000 constituting the regular Spanish forces in Cuba, but 96,000 in round numbers were left to bear arms on March 1, 1897. These numbers have more than academic interest for us just at present, for if we may assume the foregoing ratio of loss to hold good from March 1, 1897, to March 1, 1898, then after adding the reinforcements sent out during the year ended March 25, 1898, there can not be in Cuba today more than 100,000 regular Spanish troops able to bear arms. It is probable the number is somewhat less than this, but the assumption of 100,000 gives us a small factor of safety in estimating the number of men we shall need in order to overcome Spanish resistance on land in the island. It must be recollected that the foregoing figures are only approximately correct, as there is ground for the belief that the Spanish medical returns have purposely misstated the losses of the Spanish army in Cuba. But for that very reason we may feel tolerably sure that the results here given are not in excess of the truth. The above statistics are given in *Harper's Weekly*, May 7, as having been obtained in part from confidential sources.

Removal of Entire Stomach.—In the *Boston Medical and Surgical Journal*, May 5, Brigham of San Francisco, reports in detail, a "Case of Removal of the Entire Stomach for Carcinoma: Successful Esophago-duodenostomy; Recovery." The operation was performed on a woman, aged 66 years, who had complained for the past year. She had, however, been able to digest her food until Christmas time, when she vomited any solid food taken. The operation was done February 28, lasted two hours and a quarter and with a loss of blood of but two ounces. He says: "In the treatment of this case no attempt has been made to predigest the nourishment which was given to the patient. The precaution was taken, however, to supply easily digested food; and when meat was allowed it was cut in very small pieces. The food was taken slowly, whether liquid or solid. It is no hardship for the patient to live on simple food, for she has done so all her life; and especially, as age has advanced, she has been obliged to eat food that required the least chewing. The food was given of medium temperature; water was taken as it came from the pipe, and wine as it stood in the room; iced cream, of which the patient was particularly fond, was taken slowly so that it dissolved in

the mouth before it was swallowed. At first everything was too salt; as the patient got well, she wished salt on both eggs and oysters. The amount of flatus in the bowels was enough to cause pain only a few times in the early part of her illness. The urine has been normal throughout. Never since the operation has any undigested food been seen in the movements from the bowels, and for the most part these have been wholly or partly formed. The patient has vomited but a few times since the operation: twice after etherizations, twice after some laxative had been given, once after the button left its place, and twice after coughing; not more than six ounces at any one time, generally much less. On three or four occasions a mouthful of food would be regurgitated, an oyster, some shreds of meat or a few teaspoonfuls of coffee. As a usual thing the food was well retained and well digested. Milk, which would sustain most patients under such circumstances, was not liked and an important food was thus unavailable. The patient's skin is in a natural condition without any dryness; this may be due to the thorough washing which the entire body has had daily since the operation. The symptom which gave the most anxiety after the operation was the restlessness, which was unusually marked. This was without doubt the result of the surgical shock, which was caused by the removal of so important an organ as the stomach, and the interfering with its vessels and nerves. The season of the year in California, with mild sunny days, and the careful and constant nursing, are among the factors which made the operation a success. The age of the patient counted for something also; the effects of the change of life had long passed by, and there had been for many years an even condition of good health. . . . She has a fine color; complains of nothing so far as the functions of her body go; eats whatever she wishes; has no pain whatever; is of a very cheerful disposition. She is out of doors most of the day from 10 till 5 o'clock, taking occasional walks around the hospital grounds; her temperature and pulse are normal; she sleeps without an opiate. Although she has food every three hours, she feels hungry at times, and feels that she could eat twice as much as is given to her. She is gaining in weight; and her general condition at the present time, April 14, seven weeks after the operation, is satisfactory in every respect."

Army Recruiting Statistics.—The general recruiting service of the Army for the month of April shows the following:

CITY STATIONS.	White.		Colored.		Aggregate Accepted.	Total number rejected.

* Special Recruiting Officers enlisted for the general service.
(a) Opened April 21, 1898.

Duties of Army Medical Officers in the Field.—Surgeon-General Sternberg under date of May 18, 1898, has issued a circular of instructions concerning the duties of medical officers with the army in the field. It reads as follows: For the information of Chief Surgeons in organizing the Medical Department and Hospital Corps of their commands, the following relating to the duties of medical officers in the field, is published:

Duties of Chief Surgeons of Corps.—The Chief Surgeon of a Corps is held responsible for the proper and effective management of the medical service of the command. He should keep a register of the medical officers and hospital corps, making assignments and issuing orders and instructions with the approval of and "By order" of the Major-General Commanding. He should make himself acquainted with the sanitary conditions affecting the troops, the efficiency of the field hospitals and of the ambulance companies, and should call for weekly reports of sick and wounded and of the personnel and means of transportation of the Hospital Corps. All reports and papers not requiring special action should be checked off and receive the stamp of his office before transmittal. Such papers include personal reports of medical officers, monthly reports of sick and wounded, of the hospital corps and of the hospital fund, and sanitary reports from chief surgeons of brigades and divisions—with the lists of wounded called for after an engagement. A copy of the action taken on all papers referred to him or forwarded by him should be made in an endorsement book. Such papers include those relating to resignation, leave of absence or discharge on account of disability; requisitions for medical and hospital and hospital corps supplies, and all recommendations or complaints referring to the medical service or affecting the health and well-being of the troops. Copies of orders and letters should be made and placed on file, and all circulars or orders from the Surgeon-General or the Chief Surgeon of the Army should be published without delay to chief surgeons of divisions. Prior to a movement the Chief Surgeon should verify by personal inspection the condition of the hospitals and of the hospital corps companies and their trains, and should make all the arrangements needful for the probable exigencies of the campaign. He should see that the assignments by chief surgeons of divisions to positions on the operating staff of the field hospitals include the best surgical skill of each division. On the march he should accompany the staff, and acquaint himself with the topography of the country; and when an engagement is imminent he should indicate to chief surgeons of divisions the localities best suited for the establishment of the field hospitals. He should inspect these from time to time and exercise general supervision over the first aid and ambulance stations and the movement of the wounded to the hospitals. He should also supervise the movement of sick and wounded to the base or general hospitals, providing transportation and detailing medical officers and attendants for their care. When absent on such duties he should leave a competent medical officer with the staff to represent him and to inform him of important changes in the military conditions. The Commanding General should be kept informed of the work of the Medical Department, and should always be consulted in matters of importance.

Duties of Chief Surgeons of Divisions.—The Chief Surgeon of a Division supervises the medical and hospital corps service of the division, promulgating orders and transmitting official reports and papers with the stamp of his office if routine in character, or with his views endorsed thereon if the subject appears to call for this action. He should have frequent personal communication with the Chief Surgeon of the Corps, and should endeavor to carry out the views of the latter on behalf of the troops. His usual position is with the staff, but he should make frequent visits to the division hospital and the ambulance company to oversee their work. He should detail one medical officer in rotation as officer of the day who, on the march, should keep him informed of any noteworthy occurrence, and who in camp should visit each regiment of the division to report on its hygienic and sanitary conditions. Before an engagement he should see that the field hospital is properly established and that the operating surgeons and their assistants are at their proper stations. During and after the engagement he should supervise the movement of the wounded from the ambulance stations to the hospital.

Duties of Chief Surgeons of Brigades. The Chief Surgeon of a Brigade is the adviser of the Brigade Commander in all medical and sanitary questions concerning the command. He should call for a weekly (or daily as may be required) report of sick and wounded from regimental surgeons and of the detailed members of the hospital corps on duty with them. He should forward the formal reports of these surgeons, and promulgate orders from brigade and higher authorities. He should keep careful watch over the health of the brigade, reporting in writing from time to time as may be required, and consulting in emergencies with the Chief Surgeon of the Division. During and after an engagement he should supervise the work at the first aid stations and the removal of the wounded to the ambulance stations, unless on account of his superior ability he has been assigned to duty at the operating tables, in which case a competent officer should be detailed to represent him temporarily on the staff of the brigade.

Duties of Regimental Surgeons.—The regimental Surgeon is, in sanitary matters, the adviser of the Regimental Commander. On the march and in camp he should examine the sick with a view to their proper treatment and disposition. He is responsible for any unexpended medical and hospital property issued for the use of the regiment. His supplies of medicines, etc., should be renewed by requisition on the surgeon in charge of the hospital. Members of the hospital corps on duty with the division are detailed to duty with him. Daily, after sick call, he should send a morning report of sick and wounded and of the hospital corps to the Regimental Commander, with a duplicate to the Chief Surgeon of the Brigade. He should keep, as a register of sick and wounded, a retained copy of the monthly report forwarded through the offices of chief surgeons to the Surgeon-General—cases treated in the division field hospital should be borne on this report as so treated. He should forward monthly, or when his official station has been changed, a personal report on a memorandum slip. After every engagement a list of wounded of the command should be forwarded. If the regimental surgeon is, by order of the chief surgeon, placed on temporary special duty, the senior medical officer with the command will perform the duties of the regimental surgeon. During an engagement he should serve at the first aid stations.

Duties of Surgeons in Charge of Division Hospitals.—The Surgeon in Charge of a Division Hospital is responsible for the care of the sick and wounded on the march and in camp, and for the comfort and general welfare of the wounded when brought to the hospital by the ambulance service. He should direct the unpacking of the wagons for the establishment of so much of the hospital as may be necessary, and the subsequent repacking when the march is to be resumed. He should superintend the admission, return to duty or transfer to base hospitals, of his patients. As commanding officer of the hospital corps detachment, he should keep the accounts of the enlisted men on duty at the hospital. He should make timely requisition for medicines, medical and hospital stores, supplies and property, for the care, expenditure and use of which he is held responsible. He should supply regimental and other medical officers of the division with such articles as may be required and are available for the treatment of the sick. He should send a daily report of sick and wounded and of the hospital corps to the Chief Surgeon, and transmit to the Surgeon-General similar reports for the month, with a statement of the hospital fund. After an engagement he should forward lists of wounded, and on sending patients to base hospitals he should furnish transfer lists to the senior surgeon accompanying. Medical officers may be assigned to assist him in the management of the hospital. One of these should act as executive officer aiding the Surgeon in Charge in the work of supervision, and having special charge of the records. Another should superintend the cooking and diet of the hospital, drawing rations from the Subsistence Department, issuing for use and keeping the accounts of the hospital fund. He should also have special charge of the hospital stores, and of such articles of property as are connected with the cooking and serving of food. Others should be assigned as attending surgeons to care for the sick on the march and in camp, and during an engagement to look after the management of the wards, and to make notes of operative procedures, deaths and of the progress of cases for subsequent report to the Surgeon in Charge and entry on the records of the hospital.

Duties of Medical Officers in Command of Ambulance Companies. The Medical Officer in Command of the Ambulance Company is charged with the care of the pay, clothing and subsistence of his men, and is held responsible for the care of the ambulances and other wagons, tents, horses, mules, forage, etc. His subaltern officers assist him in the discharge of these duties. During and after an engagement he is responsible

for the safe and speedy transportation of the wounded on litters and in ambulance wagons from the field to the hospital by way of the first aid and ambulance stations, which latter he should organize.

Medical Officers of the Volunteer Army should make themselves familiar with the provisions and requirements of the Manual for the Medical Department, the paragraphs of Army Regulations relating to the Medical Department, the Drill Regulations for the Hospital Corps, and the chapters in Part 1 of the Handbook for the Hospital Corps, by Deputy Surgeon-General Charles Smart.

Neutralization Under the Geneva Treaty.—General Miles, commanding the Army, issued May 17, 1898, an order from headquarters, Adjutant-General's office, Washington, D. C., promulgating those articles of the Geneva treaty which will treat upon the service of civilian attaches of the medical department in the event of an invasion of Cuba, and prescribing regulations for the delivery of the red-cross brassard to such persons:

ARTICLE I. Ambulances and military hospitals shall be acknowledged to be neuter, and, as such, shall be protected and respected by belligerents so long as any sick or wounded may be therein.

Such neutrality shall cease if the ambulances or hospitals should be held by a military force.

ART. II. Persons employed in hospitals and ambulances, comprising the staff for superintendence, medical service administration, transport of wounded, as well as chaplains, shall participate in the benefit of neutrality, whilst so employed, and so long as there remain any wounded to bring in or to succor.

ART. III. The persons designated in the preceding article may, even after occupation by the enemy, continue to fulfill their duties in the hospital or ambulance which they serve, or may withdraw in order to rejoin the corps to which they belong.

Under such circumstances, when these persons shall cease from their functions, they shall be delivered by the occupying army to the outposts of the enemy.

ART. IV. As the equipment of military hospitals remains subject to the laws of war, persons attached to such hospitals can not, in withdrawing, carry away any articles but such as are their private property.

Under the same circumstances an ambulance shall, on the contrary, retain its equipment.

ART. VI. Wounded or sick soldiers shall be entertained and taken care of, to whatever nation they may belong.

Commanders in chief shall have the power to deliver immediately to the outposts of the enemy soldiers who have been wounded in an engagement, when circumstances permit this to be done, and with the consent of both parties.

Those who are recognized, after their wounds are healed, as incapable of serving, shall be sent back to their country.

The others may also be sent back, on condition of not again bearing arms during the continuance of the war.

Evacuations, together with the persons under whose directions they take place, shall be protected by an absolute neutrality.

ART. VII. A distinctive and uniform flag shall be adopted for hospitals, ambulances and evacuations. It must, on every occasion, be accompanied by the national flag. An arm-badge (brassard) shall also be allowed for individuals neutralized, but the delivery thereof shall be left to military authority.

The flag and the arm-badge shall bear a red cross on a white ground.

Additional Articles.

ARTICLE I. The persons designated in Article II of the Convention shall, after the occupation by the enemy, continue to fulfill their duties, according to their wants, to the sick and wounded in the ambulance or the hospital which they serve. When they request to withdraw, the commander of the occupying troops shall fix the time of departure, which he shall only be allowed to delay for a short time in case of military necessity.

ART. III. Under the conditions provided for in Articles I and IV of the Convention, the name "ambulance" applies to field hospitals and other temporary establishments, which follow the troops on the field of battle to receive the sick and wounded.

ART. V. In addition to Article VI of the Convention, it is stipulated that, with the reservation of officers whose detention might be important to the fate of arms and within the limits

fixed by the second paragraph of that article, the wounded fallen into the hands of the enemy shall be sent back to their country, after they are cured, or sooner, if possible, on condition, nevertheless, of not again bearing arms during the continuance of war.

REGULATIONS.

1. All persons connected with the Medical Department of the Army in the field, or referred to in Article II of the Treaty, shall wear habitually during the war, on the left sleeve of the coat, midway between the shoulder and elbow, a brassard or arm-badge, consisting of a red cross on a white ground.

2. All hospitals, ambulances, and field stations of the Medical Department will habitually display the Red Cross flag accompanied by the National flag.

3. Permits, in duplicate, for civilians to be present with the Army, in the service of the Medical Department, may be given by authority of a Division Commander; one copy of the permit will be retained by the person neutralized, and its duplicate should be forwarded promptly to the Chief Surgeon of the Army.

4. Persons neutralized under this authority will report themselves at once to the Chief Surgeon of Division for instructions.

5. The wearing of the arm brassard by any person not officially neutralized, is prohibited.

Hospitals.

THE WILL of the late William Whitewright, New York, contains a bequest of \$50,000 for the Presbyterian Hospital, for the maintenance of free beds, to be known as the "Whitewright beds," in memory of the father of the testator.—By the will of the late Mrs. Annie S. Patton of New York, the Manhattan Eye and Ear Hospital will receive \$50,000.—Mercy Hospital, Pittsburg, Pa., celebrated her golden jubilee May 11.—The formal opening of St. Margaret's Memorial Hospital, Pittsburg, Pa., erected through the munificence of the late John H. Shoenberger, who left \$850,000 for this project, took place May 10.—The following bequest was recently made known by the death of Theodore Wernway of Philadelphia, "I give and bequeath to Medico-Chirurgical College of the city of Philadelphia the sum of \$5000, free from the collateral inheritance tax, for the endowment of a free bed to be named after my deceased sister, Sarah Elizabeth Wernway."

Colleges.

THE FOURTH ANNUAL COMMENCEMENT of the New York Medical College and Hospital for Women was held May 3 with four graduates.—The Medical Department of Niagara University, Buffalo, N. Y., graduated a class of ten May 11.—Thirty degrees of Doctor of Medicine were conferred by the Detroit College of Medicine, May 12.—The Jefferson Medical College, Philadelphia, at the seventy-third annual commencement, May 13, graduated a class of fifty.—The graduating class of the Medical Department of the University of Denver numbered twelve.—The Medical Department of the University of Texas, Galveston, held its seventh annual commencement May 15.—By the will of the late Dr. Elizabeth H. Bates of Port Chester, N. Y., the University of Michigan comes into possession of an estate valued at \$125,000. The bequest goes to establish a chair of the diseases of women and children to be known as the Bates professorship in the Medical Department.

Societies.

The following recent meetings are noted:

Illinois.—Galva Medical Society, Galva, May 5.

Indiana.—Adams County Medical Society, Decatur, May 6; Kokomo Academy of Medicine, May 16; Whitley County Medical Association, South Whitley, May 12.

Massachusetts.—Barnstable District Medical Society, Hyannis, May 12; Franklin District Medical Society, Greenfield, May 10; Hampshire Medical Society, Northampton, May 12; Worcester District of Massachusetts Medical Society, Worcester, May 11.

Missouri.—Medical Society of City Hospital Alumni, St. Louis, May 19.

New York.—Binghamton Academy of Medicine, May 17; American Laryngological Association, Brooklyn, May 16-18; Cattaraugus County Medical Society, Salamanca, May 10; Medical Society of the County of St. Lawrence, De Kalb Junction, May 17; Oswego County Medical Society, Mexico, May 10; Rensselaer County Medical Society, Troy, May 10; Winchester County Medical Society, White Plains, May 17.

Ohio.—Clark County Medical Society, Springfield, May 12.

Pennsylvania.—County Medical Society, Scranton, May 10; Lebanon County Medical Society, Lebanon, May 10; Venango County Medical Society, Franklin, May 17.

Virginia.—Richmond Academy of Medicine, May 11.

West Virginia.—State Medical Association, Martinsburg, May 18-20.

Philadelphia.

PRECAUTIONS TO BE TAKEN AGAINST SMALLPOX.—Recently, warning notices were sent out by the State Board of Health of Pennsylvania to all the local boards, cautioning them against the possible introduction of smallpox into the State on account of its prevalence in the South. The origin was doubtless in Cuba, thence conveyed to Florida in January of last year, there being thirteen cases reported at that time and twelve cases in January, 1898, in one county alone. In March of the present year there was quite an epidemic in Mobile and also in Hoynesville, where 400 cases occurred, and in the entire State 1161 cases. Tennessee also suffered and in January there were 152 cases in that State. Georgia had 374 cases, South Carolina 33 during January and February, and for the same time North Carolina had 9 cases. In February and March at Middleborough, Ky., there were 176 cases. Two cases occurred in Virginia and 5 in West Virginia during February, while in Ohio there were 7 cases. Taking into consideration the importance of Philadelphia from a commercial point of view, where the disease might be propagated, the Board of Health therefore, as a preventive measure, advocates vaccination on the wholesale plan.

NEW BUILDING FOR JEFFERSON MEDICAL COLLEGE.—The historic building which has stood for many years at the corner of Tenth and Walnut Streets is to be pulled down, and a more substantial and adequate building erected. The building is to be five stories high, with a frontage on Tenth Street of 118 and on Walnut Street 107 feet. The first floor is devoted to rooms for trustees, dean, clerks, library, laboratory and a large amphitheater. The second floor will be occupied by a museum, room for experimental therapeutics and a pharmaceutical laboratory. On the third floor there will be a laboratory and rooms for chemicals, and the fourth floor will be devoted to obstetrics, bandaging and demonstration of pathology. The fifth floor will be taken up by an amphitheater accommodating 520 students, a dissecting room and an incinerating room. The college will be equipped with all the recent appliances, heated by steam and lighted by electricity.

KLEBS LÖFFLER BACILLUS IN MILK.—A few weeks ago it was reported in the JOURNAL that an epidemic of diphtheria in Philadelphia was supposed to have been conveyed through the medium of milk. In the report of Medical Inspector Taylor, recently made to the Board of Health, it was stated that for the week just passed there had been 86 cases with 22 deaths. The majority of the cases had come from the region supplied by a certain dairyman. For the same period there were: Typhoid fever, 60 cases and 9 deaths; scarlet fever, 61 cases and 7 deaths. This report shows that typhoid fever has slightly increased since the report of last week.

PHILADELPHIA MUST HAVE PURE MILK.—Some cities in Pennsylvania, including Philadelphia, recently had a thorough examination made of the milk distributed to customers. Some of the samples were obtained from the depot on the arrival of the train, others at the milk wagons and some from residences after distribution. On the whole, however, it proved to come up to the required standard. Several arrests have, however, followed, and from fines imposed there has been collected \$1094. This work has been accomplished by the dairy and food department of the State service.

FIRST AID TO THE INJURED.—Dr. Gerhard of Philadelphia is giving a series of lectures to certain members of the Red Cross Society who contemplate going into the army. The lectures so far have been devoted to fractures, which he is teaching them to treat "while the doctor is coming." Splints must be applied quickly, and under awkward circumstances anything should be converted into a splint, shingles, canes, swords, scabbards, guns, all answering this purpose. Again, they must be padded, and if no other means is at hand old clothing, grass or moss would do, being bound to the limb with green vines, suspenders or strips of clothing.

COMMENCEMENT AT JEFFERSON MEDICAL COLLEGE, PHILADELPHIA.—The seventy-fourth annual commencement of the Jefferson Medical College occurred on May 14 and fifty students received their degree. This is a smaller class than for

many years on account of the fact that the curriculum of four years has been adopted, in conformity with the standard of the best colleges of today. William Potter, president of the board of trustees, made a talk in which he praised the patriotism in offering the services of the entire class to the Government.

DR. SCHWENK OF PHILADELPHIA HONORED.—The Board of City Trusts recently appointed the above named gentleman on the staff of the Will's Eye Hospital, a vacancy occurring on the resignation of Dr. Edward Jackson. Dr. Schwenk is well liked by his professional brethren and is a member of many medical societies of the State.

MUST NOT POLLUTE THE WATER.—At a recent meeting of the city council an ordinance was proposed relative to the protection of the water-supply against Spanish trickery. It would be almost impossible for harm to come from this source on account of the number of reservoirs in the city and the large body of water, Schuylkill River, which supplies the city.

CHANGE OF ADDRESS.

Atkinson, W. H., from 707 12th N. W. to 805 12th N. W., Washington, D. C.
Allaben, J. E., from 330 W. State St. to 202 Masonic Temple, Rockford, Ill.
Billig, A., from Chicago to Pullman, Ill.
Crook, L. F., from Cresson to Hico, Texas.
Chamberlin, L. H., from Detroit to Grand Rapids, Mich.
Canright, O. S., from Palmyra to East Troy, Wis.
Cone, D. E., from Fall River, Mass., to 103 Murray St., Binghamton, N. Y.
Cattrell, D., from 279 E. Indiana to 264 E. Ohio St., Chicago, Ill.
Dyson, E. B., from Cleveland to Burton, Ohio.
Davenport, N. S., from 446 W. Congress St. to 207 Warren Ave., Chicago, Ill.
Edwards, F. H., from 330 W. State St. to 202 Masonic Temple, Rockford, Ill.
Evans, O. H., from Thurman to Limestone and Clifton Sts., Springfield, Ohio.
Faber, C. A., from 41-42 Murrell Bldg to 24-25 Burchard Block, Milwaukee, Wis.
Gasson, I. H., from Omaha, Neb., to Missouri Valley, Iowa.
Graeser, H. B., from Des Moines to Lone Tree, Iowa.
Green, E. M., from Norman, O. T., to Danville, Ky.
Hubbell, W. B., from Cleveland to Elyria, Ohio.
Holman, C. J. Johnson, from Chicago, Ill., to Renville, Minn.
Hollenbeck, F. D., from 205 N. State St. to 321 E. Chicago Ave., Chicago, Ill.
Hayden, C., from 1828 California to 2827 High St., Denver, Colo.
Hofman, Karl., from 1236 W. 15th St. to 910 Schiller Bldg, Chicago, Ill.
Jones, W. D., from Rising City to Devil's Lake, N. Dak.
Kirkbride, M. F., from Philadelphia, Pa., to Spring Lake Beach, N. J.
Kudlowski, S. L., from 312 Forest Ave. to 343 26th St., Detroit, Mich.
Luster, J. C., from Rolla to St. James, Mo.
Larned, E. R., from 320 Fifth to 202 First Ave., Joliet, Ill.
Marsee, J. W., from 106 to 206 1/2 E. New York St., Indianapolis, Ind.
Mattison, J. B., from 188 Prospect Pl. to 174 St. Mark's Ave., Brooklyn, N. Y.
McArdle, from 821 to 1120 16th St., Washington, D. C.
Noble, C. P., from 2134 Hancock to 1637 W. Broad St., Philadelphia, Pa.
Niles, J. W., from 390 N. Clark St. to 420 La Salle Ave., Chicago, Ill.
Pantzer, H. O., from 194 to 316 E. Michigan St., Indianapolis, Ind.

THE PUBLIC SERVICE.

Army Changes. Official List of Changes in the Stations and duties of officers serving in the Medical Department, U. S. Army, from May 14 to 20, 1898.

Acting Asst. Surgeon H. P. Jackson, U. S. A., will proceed from Charleston, S. C., to Key West, Fla., and report in person to Major William R. Hall, Surgeon, in charge of general hospital at that place, for duty.
Acting Asst. Surgeon Charles K. Cutter, U. S. A., now on duty at Boston, Mass., is assigned to duty as assistant to the attending surgeon and examiner of recruits in that city.
Acting Asst. Surgeon Maynard G. Burgess, U. S. A., will proceed from Washington, D. C., to Mobile, Ala., and report in person to the commanding General of the troops at that place for duty.
Acting Asst. Surgeon David Baker, U. S. A., will proceed from Waltonville, Ill., to Ft. Thomas, Ky., and report for duty in the general hospital at that place.
Acting Asst. Surgeon George H. Richardson, U. S. A., will proceed from Washington, D. C., to San Francisco, Cal., and report in person to the commanding General of the expedition to the Philippine Islands for duty.
Acting Asst. Surgeon Arthur Jordan, U. S. A., will proceed from Richmond, Va., to Mobile, Ala., and report for duty with troops in the field at that place.
Acting Asst. Surgeon Frederick J. Combe, U. S. A., will proceed from Brownsville, Texas, to Tampa, Fla., and report for duty with troops in the field at that place.
Acting Asst. Surgeon Clarence J. Manly, U. S. A., will proceed from Washington, D. C., to Ft. Thomas, Ky., and report for duty in the general hospital at that place.
Acting Asst. Surgeon Ira A. Shimer, U. S. A., will proceed from Washington, D. C., to Et. Myer, Va., and report for duty in the general hospital at that place.
Acting Asst. Surgeon George H. Penrose, U. S. A., will proceed from Salt Lake City, Utah, to Ft. Douglas, Utah, and report to the commanding officer for duty at that post.
Acting Asst. Surgeon Amos W. Barber, U. S. A., will proceed from Cheyenne, Wyo., to Ft. D. A. Russell, Wyo., and report to the commanding officer for duty at that post.
Acting Asst. Surgeon Douglas F. Duval, U. S. A., will proceed from Washington, D. C., to West Point, N. Y., and report for duty at the U. S. Military Academy.
Acting Asst. Surgeon S. Melville Waterhouse, U. S. A., will proceed from Washington, D. C., to Ft. Hamilton, N. Y., and report for duty at that station.
Major William B. Davis, Surgeon, is assigned to duty in charge of the general hospital at Ft. Myer, Va., in addition to his duties as surgeon at that post.
Major Robert H. White, Surgeon, is relieved from duty at the Presidio of San Francisco, Cal., and will report in person to the commanding General of the expedition to the Philippine Islands for duty as chief surgeon.
Major Edward B. Moseley, Surgeon, is relieved from duty at Benicla Bks., Cal., and ordered to Presidio of San Francisco, Cal., relieving Major Robert H. White, Surgeon.
Capt. George E. Bushnell, Asst. Surgeon, is relieved from duty as attending surgeon and examiner of recruits at Boston, Mass., and will report in person to the Surgeon-General of the Army, for duty in his office.
The following named medical officers, in addition to their present duties, are assigned to duty in charge of the general hospitals at the places opposite their respective names: Lieut. Col. William H. Gardner, Deputy Surgeon-General, Ft. Thomas, Ky.; Major Blair D. Taylor, Surgeon, Ft. McPherson, Ga.
Major William H. Corbuser, Surgeon, is relieved from duty at Angel Island, Cal., and assigned to duty as acting medical purveyor of the expedition to the Philippine Islands.
Capt. Charles B. Ewing, Asst. Surgeon, will proceed at once to New Orleans, La., and report to the commanding officer Fifth Cavalry for duty.
The following named medical officers are detailed to represent the Medical Department of the Army at the annual meeting of the American Medical Association to be held in the city of Denver, Colo., June 7 to 10, 1898: Lieut. Col. Alfred A. Woodhull, Deputy Surgeon-General; Major Curtis E. Munn, Surgeon.
Acting Asst. Surgeon José M. Pelgado, U. S. A., will proceed from Washington, D. C., to Tampa, Fla., and report for duty with the U. S. troops at that place.
A contract having been made with Dr. A. D. McArthur of Littleton, Colo., for duty as Acting Asst. Surgeon at Ft. Logan, Colo., he will proceed to that post and report to the commanding officer for duty, to relieve Acting Asst. Surgeon Carroll E. Edson, whose contract is about to terminate.

The Journal of the American Medical Association

VOL. XXX.

CHICAGO, ILLINOIS, JUNE 4, 1898.

No. 23.

ADDRESS.

THE ETIOLOGY, PATHOLOGY AND DIAGNOSIS OF INTESTINAL TUBERCULOSIS.

Address in Surgery, delivered at the Meeting of the Ohio State Medical Society, May 5, 1898.

BY N. SENN, M.D., Ph.D., LL.D.

PROFESSOR OF SURGERY, RUSH MEDICAL COLLEGE; ATTENDING SURGEON PRESBYTERIAN HOSPITAL; SURGEON IN-CHIEF ST. JOSEPH'S HOSPITAL CHICAGO, ILL.

Renewed interest has been awakened in the subject of intestinal tuberculosis since recent experience in modern aggressive surgery has taught the profession that some of the cases in which the disease occurs as a primary affection are amenable to successful surgical intervention. Intestinal tuberculosis appears under many different pathologic forms and presents such various clinical aspects, that it becomes necessary to acquire carefully into its etiology and pathology, in order to enable the surgeon to exercise the necessary care in the selection of cases for operative treatment. The field of abdominal surgery is rapidly increasing in extent and usefulness, and one of its most recent acquisitions is the successful treatment of certain forms of intestinal tuberculosis.

It is my intention on this occasion to discuss as briefly as possible the etiology, pathology, symptoms and diagnosis of this affection of the intestinal canal, with special reference to the indications which dictate and warrant surgical interference.

Frequency of intestinal tuberculosis.—Intestinal tuberculosis is a very common complication of pulmonary and miliary tuberculosis. It is not often met with as a primary affection. In one thousand tubercular subjects examined postmortem in the Pathological Institute at Munich between the years 1886 and 1890, only one case of primary intestinal tuberculosis was noted, while in 566 cases secondary intestinal tuberculosis was seen.

That the disease occasionally occurs as a primary affection can no longer be doubted; the results of an enormous clinical experience and thousands of necropses furnish a substantial verification of this fact. There can, however, be but little doubt that in many cases of tuberculosis of the intestine in which the clinical features point only to this organ as the sole seat of disease, careful search would reveal old, perhaps latent tubercular foci in some other part of the body. The prudent surgeon selects for his operative work only the cases in which he has reason to believe, from the clinical history and the signs and symptoms presented, that the disease is limited and confined largely if not entirely to the intestinal canal.

Tuberculosis of the stomach.—As primary intestinal tuberculosis is for the most part a feeding disease, it is interesting to know whether or not the stomach is ever the seat of tubercular infection. For good reasons it has for a long time assigned to the gastric juice a

destructive, or at least an inhibitory effect on pathogenic bacteria, but the results of experimentation and clinical observations seem to combine in proving that the virulence of the bacillus of tuberculosis is little if any impaired on its way through the stomach. It is natural to assume that in cases in which the physiologic activity of the glandular appendages of the stomach is lessened, the antiseptic properties of the gastric secretions would be correspondingly diminished. The correctness of this statement is borne out by the experience of many reliable clinicians and by the results of experimentation on the lower animals. Blumer (*Albany Medical Annals*, March, 1898) reports a case of tuberculosis of the stomach in which he found postmortem an old caseous area at the apex of the right lung which had softened at the lower part, general miliary tuberculosis, tuberculous ulcers of the stomach and ileum, tuberculosis of the kidneys and of the aorta. The stomach lesion consisted of three or four small, shallow, circular ulcerations, and near them, numerous miliary tubercles. Blumer has studied the literature of the subject and finds but thirty cases on record, in all of which the gastric lesion was secondary to tuberculosis elsewhere. He divides the reported cases into miliary tuberculosis, and single and multiple ulcerations. Four were cases of pure miliary tuberculosis of the stomach wall; about eight were single and the remainder multiple ulcers.

Tuberculosis of the stomach usually occurs only in connection with similar affections of other organs, especially the intestinal and lymphatic glands. The ulcers are pale and have thickened edematous edges. The inflammatory product presents the usual evidences of the nature of the disease—giant cells, bacilli and perhaps cheesy material. The disease in this locality presents no characteristic symptoms. Perforation and hemorrhage may occur under the same circumstances as in intestinal tuberculosis. The ulcer presents a sharp contrast to its dark-colored surroundings. In a few cases the serous coat over the floor of the ulcer is studded with miliary tubercles. In Litten's case the tuberculosis of the digestive tract was limited to the stomach. Similar cases have been described by Talamon-Balzer, Gilles and Eppinger. Musser (*"Tubercular Ulcer of the Stomach," Philadelphia Hospital Reports*, Vol. i, p. 117) found a tubercular ulcer of the stomach one and one-half by three and one-half inches on postmortem examination of a patient who had died of pulmonary tuberculosis. Tubercle bacilli were found in the cheesy material. Most of the cases of tubercular ulcer of the stomach have been observed in children. The disease presents no characteristic symptoms. Musser claims that death in these cases often results from hemorrhage.

Tuberculosis of the stomach is a very rare affection, as is shown by the researches of Letorey (Thèse de Paris, 1895), who was able to find an account of only

twenty-one cases. This rarity is explained, to a certain extent, by the well known action of the gastric juice on the bacillus tuberculosis, which either dies or loses its virulence in an acid medium. Absence or diminution of hydrochloric acid would therefore favor the development of tubercular lesions, as would also other affections which impaired the digestive functions of the stomach. Letorey believes that the bacillus reaches the stomach more frequently by the way of the circulation than by entrance with infected food. The disease is more frequently demonstrated in the autopsy room than at the bedside. The usual site of the ulceration is near the pylorus and on the larger curvature. In only six cases out of the twenty-one was more than one tubercular ulcer noted, so that the lesion may be said to be generally single, the ulcer round or oval, with ragged and bleeding edges and a grayish-yellow floor. The ulcer occasionally reaches a diameter of from three to five centimeters. The prognosis in these cases is grave, since the patient usually dies from the effects of the primary pulmonary affection or tuberculosis of other organs, the gastric complication perhaps hastening the fatal termination. The occasional occurrence of tubercular gastritis is the best possible proof that the bacillus of tuberculosis may pass through the stomach, subjected to the action of the gastric juice, and still retain sufficient virulence on its entrance into the intestinal canal to exercise its specific pathogenic action upon the tissues prepared for its reception and multiplication by hereditary or acquired predisposing causes.

Etiology.—Primary tuberculosis of the intestinal canal is the result of infection from without by the ingestion of food contaminated with the essential cause of the disease, the bacillus of tuberculosis, usually in the form of tubercular milk and meat. The secondary form is caused by auto-infection by the entrance of tubercular sputa into the intestinal canal. The lymph follicles and Peyer's patches furnish the most favorable anatomic conditions for the localization and growth of the tubercle bacillus. Klebs believes that the introduction into the intestinal canal by the swallowing of sputa in phthisical patients is a frequent cause of intestinal tuberculosis. He discovered two tubercular ulcers in the stomach of a patient who had died of pulmonary tuberculosis. The supposition that intestinal tuberculosis is often caused by the ingestion of tubercular food or sputa is supported by the experiments of Malin, Parrot and Bonley, who found that animals fed with the expectorations of consumptives died of tuberculosis; while Chauveau, Bollinger and others succeeded in producing intestinal tuberculosis by feeding animals susceptible to the disease with fragments of tubercular lungs or with raw tubercular meat. The experiments of Gerlach, Zürn and Klebs demonstrated the dangers attending the use of milk from tubercular cows. In these experiments it was noted that the disease commenced in the form of an intestinal catarrh, and that the extension of the tubercular infection began through the mesenteric glands before the development of diffuse miliary tuberculosis. W. Zinn ("Ein Fall von Fütterungstuberculose bei einem erwachsenen Menschen, mit Ausgang in Miliartuberculose," *Münch. Med. Wochenschrift*, 1895, No. 37) observed a man 29 years of age who in the course of nine weeks died of acute miliary tuberculosis. The autopsy showed that the miliary tuberculosis had its origin in a mass of caseous tubercular mesenteric glands. No other old tubercular deposit could be

found. In the intestine, at a point corresponding to the diseased glands, was found the scar which followed the healing of a tubercular ulcer. The ulcer was evidently the primary lesion which led to tubercular lymphadenitis, and finally death followed from reinfection of the body from the tubercular glands, long after the intestinal ulcer had healed. General infection in this case took place through the thoracic duct. Wyss ("Zur Kasuistik der primären Darmtuberculose im Kindesalter," *Correspondenzblatt f. Schweiz. ärzte*, 1893, No. 22) found in seventy-one postmortems on children three instances of undoubted primary intestinal tuberculosis. In one case, a girl $5\frac{3}{4}$ years old who had died of diphtheria, a solitary tubercular ulcer was found in the ileum with extensive tuberculosis of the mesenteric glands. No trace of tuberculosis could be detected in any other organ. Upon inquiry it was ascertained that the child had been fed on milk almost exclusively for some time before she contracted diphtheria. In the other two cases the disease could be traced to the same cause.

Intestinal tuberculosis is found most frequently in children and young adults, although no age is entirely exempt. In the language of Virchow: "the predisposition to tuberculosis, the hereditary vulnerability resides in the tissues, and that the younger and more incompletely developed these are, the more readily will the vulnerability manifest itself in the presence of exciting causes." This may explain the special frequency of intestinal tuberculosis in children and in subjects affected by antecedent inflammatory affections of the intestinal mucous membrane.

Baumers ("Recherches sur la maladie propre aux enfants") first called attention to intestinal tuberculosis in children, which has been known as *tabes S.*, *phthisis mesaraica*, *febris mesaraica*, *febris xanthus infantum* and *intestinal scrofula*. Intestinal tuberculosis in children results in early and extensive infection of the mesenteric glands, from which reinfection usually terminates life by miliary tuberculosis. Secondary tuberculosis appears to be more frequent in adults than in children. In children intestinal tuberculosis is not within 30 to 40 per cent., in the adult in 60 to 70 per cent. The local predisposing lesion, although important in determining localization, is not essential, as the tubercle bacilli can penetrate the intact mucous membrane.

In six of Czerny's cases subjected to operative interference the patients were between 25 and 50 years of age, the average age being 39. In four of the cases tuberculosis was hereditary, in two cases the disease followed typhoid fever, and in one it was preceded by an acute attack of parametritis. In three of the cases the intestinal disease was complicated by pulmonary tuberculosis, and in one by diffuse miliary tuberculosis. In one case the infection occurred by the rupture of a tubercular adnexal abscess into the intestine, and in another the intestinal tuberculosis was complicated by actinomycosis.

Clinical experience has shown that intestinal tuberculosis pursues a more benign and chronic course in the adult than in children, and consequently the primary form of intestinal tuberculosis amenable to successful surgical treatment is met with most frequently in young adults and persons of advanced age, seldom in the case of infants and young children.

Infection from the blood is undoubtedly of quite common occurrence in primary and secondary intestinal tuberculosis. The most favorable cases for suc-

successful surgical intervention are those in which a localized predisposing lesion furnishes an infection at the entrance of tubercle bacilli into the tissues. These are the cases in which characteristic solitary or multiple tubercular ulcers develop which manifest an intrinsic tendency to heal, and in which an operation finally becomes a necessity after symptoms of obstruction indicate the existence of a cicatricial stenosis.

Pathology.—Intestinal tuberculosis presents itself clinically and pathologically in the form of a chronic catarrhal or ulcerative enteritis. The inflammation which follows the tubercular infection is characterized by a series of pathologic processes common to all tubercular affections, influenced and modified, however, by the structure and function of the tissues involved. The primary seats of infection are the glandular appendages of the mucous membrane, the lymph follicles and Peyer's agminated glands. The mode of infection resembles typhoid fever in many respects. The lower portion of the ileum and the ileo-cecal region are the most frequently infected, although any portion of the intestinal canal may be involved primarily or by extension. Of six cases of intestinal tuberculosis reported by Schiller ("Ueber die Darm Operationen an der Heidelberger Chirurgischen Klinik aus den letzten vier Jahren." Dissertation, 1896), which were operated upon by Czerny during a period of four years, the disease involved the ileo-cecal region four times, and the descending colon twice. In all cases of cecal tuberculosis operated upon by Czerny, the ulceration was limited on one side by the ileo-cecal valve; the mucous membrane of the cecum was extensively ulcerated, presenting elevations and depressions and polypoid excrescences between the ulcers; the cecal wall was much thickened and indurated. The lumen of the cecum was usually found contracted, the stenosis being the direct cause of the intestinal obstruction. In one case the mechanical impediment was found to be a sharp flexion at the insertion of the ileum into the cecum. In one case the contracted lumen of the cecum was divided by a band of cicatricial tissue. The bowel below the obstruction was, as is always the case, nearly empty, reduced in size and anemic, while on the proximal side reverse conditions existed, which facilitated circular suturing after excision. In acute cases, such as are observed in children, and which seldom come to the notice of the surgeon, the disease is usually diffuse and often implicates a large section of the intestinal canal above the ileo-cecal valve. Tuberculosis is apt to attack a portion of the intestinal canal subjected to mechanical irritation, as is the case in hernia.

A number of cases of tuberculosis of hernia have been reported. Bruns ("Beiträge zur Klin. Chirurgie," B. ix, p. 206) adds one new case to those previously published. In these thirteen cases the hernial sac was attacked ten times, and in seven it was alone the seat of disease. This, together with other conclusions, substantiate the belief, that "tuberculosis of hernia" may occur as a primary disease; generally, however, it is associated with peritoneal tuberculosis.

It appears from the present literature on the subject that tuberculosis in the ileo-cecal region and the colon is usually a disease of adults, although there are a few cases on record in which the intestinal canal at and below the ileo-cecal region was affected in children not more than 10 years of age.

Reclus (*Le Bulletin Médicale*, June 25, 1893) has

called attention to the rapidly increasing number of cecal tuberculosis cases which have been operated upon. The cases of Bouilly, Terrier, Hartmann, Reynier, Broca, Roux, Salzer, Billroth and Hochenegg, the anatomical researches of Duguet, Spillmann, Hérard, Cornil and Hanot, and the more recent descriptions of Pilliet and of Le Bayou have thrown some light upon this hitherto but little recognized affection. This affection may manifest itself as a localized tuberculosis without infiltration and as a purely local disease. This suffices to place this intestinal lesion among the surgical tuberculosis. From the moment it is a limited focus and this focus is accessible, in such favorable circumstances intervention is legitimate. The greatest number of cases of cecal tuberculosis so far reported have been over 25 years of age.

It seems that two distinct anatomico-pathologic forms may be described, associated with different symptoms; the one a fibrous and the other an ulcerating variety; moreover, these may be combined, or there may be noticed many intermediate stages between the varieties. The majority of cases thus far reported have been characterized by an abundant tissue proliferation, which imparted to the swelling much of the aspects of carcinoma. The inflammatory mass is almost always found freely imbedded in plastic adhesions, and it is difficult if not impossible to outline the anatomic landmarks of the parts involved. Ordinarily the lesions are most marked around the ileo-cecal valve. The appendix is generally affected and constitutes a portion of the inflammatory mass.

The second or ulcerated form may present thickening of the peritoneum and adhesions around the intestinal loops, but these have not the remarkable hypertrophy of the other form; on the contrary the ulcerative process predominates, the mucosa has often completely disappeared, especially at the site of the ileo-cecal valve. Ulceration often leads to abscess and fistula formations. The fistulous openings are often multiple.

Cornil believes that in such cases the primary infection takes place in the appendix vermiformis, more especially when it is the seat of a fecal concretion or foreign body.

The tubercular infection may take place in the upper portion of the intestinal canal. Claude ("Ulcerations tuberculeuses du duodénum," *Bulletin de la Société anatomique de Paris*, No. 8, 1896) made a postmortem on a man 33 years of age who had died of pulmonary tuberculosis. He found tubercular ulcers in the upper portion of the duodenum; four other ulcers were found in the ileum. He attributed the intestinal disease to infection from the blood. During life this patient never showed any symptoms referable to the intestinal canal. The tubercular nature of the intestinal affection was established by histologic and bacteriologic examinations.

The entire length of the intestinal canal is seldom affected by tuberculosis, and in the exceptional instances when this is the case the disease pursues a rapidly fatal course. It has already been stated that intestinal tuberculosis always begins in the lymph follicles or Peyer's patches. The tubercular process is at first submucous, and reaches the surface only after degeneration and ulceration have taken place. The glands become swollen, can be felt under the epithelial lining as small hard nodules, which present a grayish color before caseation sets in. With the onset of caseation the swelling increases in size and

assumes a yellowish color. As soon as the overlying epithelial lining is destroyed softening of the inflammatory product and ulceration set in. The primary ulcer is small and round with yellowish margins. At the time the crater-like defect takes place the mass is not larger than a hemp-seed. Such small ulcers may heal, but more frequently progressive extension takes place in the direction of the blood vessels. In Peyer's patches the appearance of sieve-like defects can be seen during the early stages of the disease, which Rokitansky described as primitive tubercular ulcerations. They constitute the preparing stage or secondary tubercular ulcers. Even in superficial ulcers tubercles can constantly be found between the muscular fibers. By confluence and progressive infection the surface defects increase in size. Not infrequently remnants of intact mucous membrane remain between the different points of ulceration. The shape of the ulcer is variously modified by the confluence of several ulcers. The most extensive ulcers are found in the cecum, colon and terminal portion of the ileum.

The intrinsic tendency of intestinal tubercular ulcers is to increase in size in the direction of the blood vessels; that is, transversely to the long axis of the bowel, a pathologic feature which was first pointed out by Rokitansky (*Lehrbuch der path. Gewebelehre*, 1871, p. 327). The tubercular infection follows the lymph sheath of the blood vessels. Through the lymphatics the infection extends to the serosa, upon the surface of which miliary tubercles are often found over an area corresponding in extent to the base of the ulcer. The mesenteric glands are infected through the same channels. In children the mesenteric glands are often affected without an antecedent intestinal lesion. In such cases the tubercle bacilli penetrate through the mucous membrane and enter the lymphatic system without producing a demonstrable surface lesion, or infection takes place by the way of the general circulation. Infection through the mucous membrane undoubtedly is often determined by catarrhal enteritis, which damages the epithelial lining and prepares the way for invasion from the intestinal canal.

Extension of the ulcer in the muscular coat takes place by progressive extension of the ulcerating process and by diffusion of the infection through the lymph channels (Figs. 1 and 2). As soon as the serous coat is reached secondary plastic peritonitis is almost the constant result. Usually the peritonitis is limited to the affected portion of the bowel, between which and the adjacent viscera firm adhesions are formed. In exceptional cases the peritonitis becomes profuse without perforation. More frequently, however, the diffuse tubercular peritonitis is caused by the rupture of a peri-intestinal tubercular abscess. Perforation of a tubercular ulcer is often prevented by early and firm adhesions. In one of the cases reported by Rindfleisch the intestine was found perforated at five different points without causing diffuse peritonitis, owing to the existence of firm adhesions. Perforative peritonitis is so rare in intestinal tuberculosis that Leube saw only two cases during his service in the clinic at Erlangen. Leudet reports six cases that occurred in his practice, which were due to tubercular affection of the appendix. Eisenhardt (*"Ueber die Häufigkeit und Vorkommen der Darmtuberculose," Dissertation, Munich, 1891*) found perforation in 28 out of 566 cases of intestinal

tuberculosis examined postmortem. Extension of the disease to other parts and organs frequently takes place through the lymphatic system.

Tubercular lymphadenitis is a frequent and, in

long-standing cases, a constant concomitant pathologic condition, as was first pointed out by Schüppel and Rindfleisch. The observations occurring during operations made for intestinal tuberculosis and the

Figure 2.—Diffuse annular tubercular ulcer of ileum. [Pathological Museum Rush Medical College.]

results of postmortem examinations combine to show that retrograde metamorphosis of the inflammatory product of the tubercular glands takes place very slowly. The writer has seen repeatedly tubercular

mesenteric glands as large as a hazel-nut which had not undergone any decided cheesy degeneration. Coagulation and caseous degeneration, however, occur in the course of time, but liquefaction and abscess formation in and around tubercular mesenteric glands are of rare occurrence. Infiltration and thickening of the intestinal wall occur most frequently and reach the maximum height in cases in which the tuberculosis is located in the ileo-cecal region or colon. In these localities the disease is most frequently primary, a fact which would explain its chronicity and comparatively benign nature. When the tubercular process affects this part of the intestinal canal the resultant swelling is often of larger size and has frequently been mistaken for malignant disease. In such instances the intestinal wall has been found several centimeters in thickness.

In acute cases of intestinal tuberculosis the ulcers manifest little or no tendency to repair. In chronic cases attempts at healing or complete healing is the rule. Eisenhardt (*op. cit.*) in examining the post-mortem records of 566 cases of intestinal tuberculosis, found that healing was completed in only 10, while in 25 instances the ulcers were only partly healed.

Attempts at cicatrization are frequently seen, but very often while healing is going on in one part of the ulcer progressive infection and destruction are witnessed in another portion. The healing of a tubercular ulcer of large size requires an enormous quantity of new material, which is composed largely of new connective tissue. The scar tissue always evinces a tendency to contraction, which leads to stenosis and flexion. If the ulcer is circular, healing is attended by contraction of the lumen of the bowel, which finally leads to intestinal obstruction. If only one side of the circumference of the bowel is ulcerated, healing will result in contraction and flexion. The healing of several tubercular ulcers gives rise to the development of multiple strictures, which have been found by several surgeons in operations for intestinal obstructions. Progressive cicatricial contraction may eventually result in almost complete obliteration of the lumen of the bowel. In one of Scheuer's cases the stricture at the time the intestinal resection was performed for obstruction was so narrow that it admitted only a probe three millimeters in size. The healing of intestinal tubercular ulcers is seldom followed by complete recovery, as all such patients are liable later to intestinal obstructions and reinfection from the tubercular mesenteric and retroperitoneal glands.

Symptoms.—Intestinal tuberculosis may run its entire course from beginning to end without any symptoms which would point to the intestinal canal as the principal seat of the disease. Tubercular ulcers of the intestines are often found at autopsies without the slightest evidence of their existence during life. That an isolated tubercular ulcer of the intestine may exist without causing symptoms before perforation occurs, is shown by a case reported by Baumgarten ("Ueber latente Tuberculose," Volkmann's *Klinische Vorträge*, No. 218). A young soldier, in almost perfect health, died suddenly of perforative peritonitis. The postmortem revealed, as the cause of the peritonitis, a solitary perforated ulcer, the size of a penny, in the lower portion of the ileum. Microscopic examination of the tissues demonstrated the tubercular nature of the ulcer. No evidence of tuberculosis was found in any other organ of the body.

In other cases the symptoms are misleading. Thus Leonhardi-Aster (Ueber einen unter dem Bilde pernicioser Anämie verlaufenden Fall von Darmtuberculose," *Deutsche Zeitsch. f. prakt. Med.*, 1878, Nos. 8 and 9) recorded a case of intestinal tuberculosis which presented all the clinical features of pernicious anemia, the intestinal symptoms being masked by the progressive anemia for which no cause could be assigned until the necropsy revealed the characteristic pathologic lesions of intestinal tuberculosis. In cases of diffuse acute intestinal tuberculosis the most important and prominent symptoms point to the existence of an intestinal catarrh. Profuse diarrhea is seldom absent, the stools being copious and liquid. Colicky pains referred to the umbilicus, slight tenderness on deep pressure, progressive emaciation and more or less rise in temperature, especially toward evening and during the night are symptoms well calculated to arouse suspicion in regard to the probable tubercular nature of the intestinal disease. Enlarged mesenteric glands can often be palpated through the thin and relaxed abdominal wall. In some cases enlarged mesenteric and retroperitoneal glands can be detected by vaginal or rectal examination. The severity of the diarrhea is attributable more to the existence of the complicating intestinal catarrh and increased peristalsis than to the ulcers themselves. Pulmonary tuberculosis, as well as tuberculosis of any other important organ, often overshadows and masks the intestinal complication. In all cases of pulmonary tuberculosis attended by diarrhea, which does not yield to the ordinary treatment, we have reason to assume the existence of intestinal tuberculosis. In primary intestinal tuberculosis the early symptoms set in insidiously, the disease is usually mistaken for an ordinary intestinal catarrh and is regarded as such until the negative results obtained from the treatment induces the physician to make a more thorough investigation of the case. The suspicions of the tubercular nature of the intestinal disease are materially strengthened if it can be ascertained that the patient has made unsterilized milk a staple article of diet.

The frequent presence of traces of blood in the stools is decidedly suspicious. If the ulcers are located in the small intestine the blood is intimately mixed with the stools; if in the large intestine the extravasated blood often forms a coating for the otherwise well formed fecal masses. Pus in the stools is found, as a rule, only when the tubercular process involves the lower portion of the large intestine. In the small intestine the pus that forms on the surface of the ulcers is speedily washed away with the intestinal discharges and, on the other hand, pus formation is checked by the peptic action of the intestinal juice, which acts as an efficient antiseptic. Bamberger has called attention to the character of the stools in intestinal tuberculosis, which according to this authority frequently contain transparent particles of mucus resembling frog spawn or boiled sago grains. These masses of mucus are probably formed in and are discharged from the lymph follicles of the intestinal mucous membrane, the structures primarily affected by the tubercular process.

Virchow places less diagnostic importance on the presence of this pathologic product, which he believes has often been mistaken for partially digested starch.

The partial or complete healing of a tubercular ulcer of considerable size is usually announced clinically by the appearance of a complexus of symptoms which

indicates the existence of chronic intestinal obstruction, caused by the cicatricial stenosis which so constantly attends and follows the healing of a tubercular ulcer. Intermittent colicky pains in the umbilical region, diarrhea alternated with constipation, and perhaps occasional attacks of vomiting, are the most prominent clinical manifestations in such cases. Chronic intestinal obstruction from this, as well as other causes, often terminates in an acute attack. In rare cases, the chronic obstruction presents few or no symptoms until symptoms of acute obstruction set in, when operation or autopsy reveal the presence of an old cicatricial stenosis, which was never suspected before the abdomen was opened.

The formation of a chronic abscess in the ileo-cecal region, or any part of the abdominal wall, in connection with intestinal symptoms of long standing, always suggests the probable existence of a tubercular intestinal ulcer. The writer has always observed these in the ileo-cecal region, over the ascending colon, and in one case in the umbilical region. These are the cases in which, prior to the perforation of the ulcer, adhesion takes place, excluding the peritoneal cavity, followed by the formation of a mural tubercular abscess. In more than one case the tubercular nature of the abscess and its intestinal origin were predicted before the abscess was opened. A fecal fistula is sure to follow the opening of such an abscess. The granulations

Peritoneal tubercle showing bacilli. A, visceral peritoneum. Eye piece 4, obj. 1. 12.

lining the abscess cavity may for a time prevent the escape of intestinal contents, but in the course of a few days or weeks the granulations give way and the fecal fistula appears. If the disease is attended by plastic peritonitis to any considerable extent the inflammatory exudate may often be distinctly outlined by palpation.

Voelhs calls attention to a condition of diagnostic value, often met with in such cases, in the form of indurated plates in the peritoneum of almost cartilaginous hardness.

Such areas of induration are not only found in the ileo-cecal region, along the course of the colon according to the seat of the disease, but also in Douglas' fossa. In the pelvis these indurations may grow to actual exudates of considerable size, which in women might be mistaken for diseased adherent ovaries or tubercular Fallopian tubes.

In four out of six cases operated upon by Czerny a diagnosis of probable intestinal tuberculosis was made before the operation was performed. The diagnosis was based largely upon the clinical history which indicated the existence of a cicatricial stenosis in the

ileo-cecal region and the presence of a swelling, which on percussion yielded a dull tympanitic resonance, and which was movable and only slightly tender on pressure, and the periodic abdominal pains caused by exaggerated intestinal peristalsis, as described by Czerny, König and Benoit.

The anatomic location of the stricture is indicated by clinical phenomena which deserve a careful study and analysis. Stenosis of the duodenum above the entrance of the bile duct, gives rise to the same symptoms as stenosis of the pylorus, but below this point it is attended by symptoms which not only simulate the latter affection, but also obstruct the entrance of bile into the intestinal canal.

The most important condition which characterizes duodenal stenosis below the bile duct, is the constant presence of bile in the chyme and repeated ejections of the fluid by vomiting. On the other hand, of three clinical observations Boas ("Ueber die Stenose des Duodenum," *Deutsche med. Wochenschrift*, 1891, No. 28), shows that fluid taken from the stomach

Tubercular intestine. A, necrotic mucosa; B, tubercle in submucosa; C vessels. High power.

contains not only bile but also pancreatic juice. The contents of the stomach possessed all of the chemical properties of duodenal chyme.

Duodenal differs from pyloric obstruction also by the absence of a corresponding dilatation of the stomach, by the absence of the products of fermentation of the stomach contents and by the absence of sarcinae and yeast cells. No distinction can be made between obstruction in the lower portion of the duodenum and the upper part of the jejunum. Vomiting of large quantities of bile indicate duodenal obstruction, while the ejected material assumes more and more the character of feces, the lower the location of the obstruction. In eight out of twelve cases of duodenal obstruction, collected by Gerhardt and Hagenbach, the disease was due to carcinoma, cysts or hemorrhage of the pancreas. The search for the pancreatic juice in the stomach contents is important. The number of well authenticated cases of tuberculosis of the duodenum have been placed on record, and there is no reason to doubt that in isolated cases the ulceration might heal with the usual remote conditions following cicatricial stenosis and intestinal

obstruction. If the cicatricial stenosis involves the ileo-cecal region, or any part of the colon, the usual symptoms indicative of intestinal obstruction in these portions of the intestinal tract, will develop. Diarrhea is the most constant symptom in such cases. In far advanced cases extensive tympanites, fecal vomiting and complete interruption of the fecal circulation at the point of obstruction complete the clinical picture of intestinal obstruction.

Diagnosis.—The diagnosis of secondary tuberculosis of the intestines presents few difficulties if the primary disease is well marked, and affects an organ readily accessible to examination. Pulmonary phthisis generally precedes and attends secondary intestinal tuberculosis. In women, tuberculosis of the internal genital organs occasionally constitutes the primary affection, and extension takes place to the intestinal canal, either through the lymphatic channels or, as in one of Czerny's cases, by rupture of a tubercular abscess into the intestinal canal. In cases of primary intestinal tuberculosis, an early correct diagnosis is seldom made. There are other ulcerative affections of the intestines which in many respects resemble

produced the chronic intestinal catarrh. Examination of the lungs and other important organs failed to locate a tubercular focus. The mesenteric glands could not be felt on palpation and rectal examination. The stools were frequent and liquid. The pain slight and referred to the umbilical and hypogastric regions.

Intestinal tuberculosis was suspected. Carbonate of guaiacol and salicylate of bismuth were administered internally and the colon was washed out daily with a copious enema of warm salt solution. On many different occasions the stools were examined for tubercle bacilli, but none could be found. Myriads of colon bacilli and micrococci were invariably found. The absence of tubercle bacilli in the stools and the marked improvement which followed the treatment, leave but little doubt that this was a case of intestinal ulceration, caused by infection with the colon bacillus.

Bacteriologic examination of the feces in suspected cases of intestinal tuberculosis should never be neglected, as it often furnishes positive proof of the tubercular nature of the disease. Tubercle bacilli, when present in the feces, in which they may be demonstrated by the same methods as in sputum, are indica-

Tubercular intestine. Low power. Cross section of ulcer. A, necrotic mucosa; B, tubercles in submucosa; C, invasion of muscular layers; D, peritoneal tubercle with giant cells.

intestinal tuberculosis. Councilman ("Johns Hopkins Hospital Reports," March, 1892) reports a case of extensive and deep ulceration of the lower portion of the ileum complicated by stricture of the rectum, which terminated in death from perforation and gangrenous periproctitis, and in which typhoid fever and tuberculosis could be safely excluded as causes. At the postmortem, ulceration of the ileum was found, with invasion of the tissues by colon bacilli. Some of the ulcers presented the appearance of an acute process, others were of a chronic nature. Numerous bacteria, both short rods and micrococci, were found in the superficial necrosed tissue, in some places extending into the cellular infiltration in the submucosa. These microbes did not seem to stand in any direct etiologic connection with the pathologic changes. The writer recently had under his observation for several months a case of chronic diarrhea, which had resisted all remedial measures. The patient was a man about 30 years of age, very anemic and greatly emaciated. No hereditary tendency to tuberculosis, and no cause could be ascertained, which might have

tive of intestinal tuberculosis, providing that they are observed upon repeated examination, and that clinical symptoms are present which point to the intestines as the seat of disease, as otherwise they may be referable to swallowed sputa.

The best way to find the bacillus is to dilute the feces with distilled water and to prepare and strain the deposit after centrifugation. Sawyer (*Medical News*, May 23, 1896) urges the importance, in cases of suspected intestinal tuberculosis, of examining the mucus collected from the rectum, just above the sphincter ani, for bacilli. When found, particularly on the surface of fissured stools, these clusters of bacilli are of diagnostic value, and may be relied on to indicate tubercular processes in the intestinal tract. He has thus found them in several cases when they could not be found in the sputum, or when sputum could not be obtained.

If the tubercular enteritis has progressed to the formation of cicatricial strictures, the differential diagnosis between intestinal obstruction from this cause and other inflammatory affections which result

in ulceration and cicatricial stenosis, is always difficult and sometimes impossible. In such cases a probable diagnosis must rest on a careful study of the clinical history and search for tubercular foci in other organs.

Congenital stricture.—Congenital stenosis of the intestinal canal may appear as a single or multiple congenital defect, may affect any portion of the intestinal canal and may cause no symptoms until long after birth. Intestinal stricture occurring in infants, children and young adults, without any history of the existence of an antecedent ulcerative lesion, is quite frequently of a congenital origin.

Traumatic stricture.—If in cases of intestinal obstruction from a stricture the clinical history shows that the patient has been for some time in the past, the subject of an injury to the abdomen it should be borne in mind that the stricture may be the direct result of the trauma. Such strictures are occasionally caused by a blow on the abdomen. Mygiud reports such a case. Intestinal resection was performed six months after the accident for symptoms of obstruction, and the patient recovered.

Traumatic strictures may result from laceration of the mucosa or from plastic peritonitis. In the former variety the lesion of the mucous membrane would be likely to simulate more closely tubercular enteritis than the peritonitis form. In both instances, however, the catarrhal enteritis complicating the chronic obstruction would present some clinical features in common with tubercular enteritis.

Stricture following strangulated hernia.—It has been known for a number of years that intestinal stricture occasionally develops after the reduction of a hernia by taxis or operation. The stricture in such cases is caused by a circular necrosis of the mucous membrane, resulting from the pressure by the strangulation. The elimination of the necrosed tissue is followed by ulceration, and the healing of the circular ulcer finally leads to cicatricial contraction and intestinal stenosis. Garré first described intestinal stricture as one of the remote results of a strangulated hernia. ("Ueber eine eigenartige Form von Darmstenose nach Brucheingklemmung." *Beiträge zur klin. Chirurgie*, B. ix.) He made the observation that in some cases of strangulated hernia the mucous membrane of the bowel at the point of constriction becomes necrotic and is cast off as a slough. The circular defect heals by granulation, and the resulting scar leads to circular constriction.

In his first case the symptoms of obstruction necessitated a laparotomy, which was performed nine weeks after the herniotomy. The patient was 27 years old, and the subject of a preperitoneal inguinal hernia. Intestinal resection to the extent of forty-one centimeters was made, and the continuity of the bowel restored by circular enterorrhaphy. The patient recovered. Examination of the specimen removed showed that the ulcerated surface had not entirely healed. At one point the ulceration extended as far as the peritoneum.

Ravault ("Rétrécissement cicatriciel de l'intestin au niveau des 2 points de l'étranglement d'une ancienne hernie," *Bull. de la Soc. anat. de Paris*, 5, Série iv) reports a case of double cicatricial stricture of the small intestine which caused death from acute intestinal obstruction. Several years before the last illness the patient was operated upon successfully for strangulated hernia. The acute attack of intestinal obstruction resulted

fatally in a few days. The necropsy revealed two strictures eight centimeters apart; the segment of bowel between them was distended by gas. Above the stricture on the proximal side the bowel was greatly distended and vascular, while the intestine below the second stricture was contracted, empty and pale. The strictures were undoubtedly the result of sloughing, ulceration and scar formation, consecutive pathologic conditions caused by harmful circular constriction by the neck of the hernial sac.

The time of the appearance of symptoms of obstruction in this form of intestinal stenosis varies from a few days to a year or more. Pitt records a case of femoral hernia in which symptoms of obstruction appeared five days after the reduction of the strangulated hernia, while in Garré's case the symptoms of obstruction did not set in until nine weeks after the relief of the strangulation by taxis.

The possibility of the existence of a cicatricial stricture due to such a cause must be remembered in cases of intestinal obstruction in which the clinical history refers to strangulated hernia relieved either by taxis or operation.

Stricture following healing of typhoid ulcer.—The healing of typhoid ulcers is very rarely followed by cicatricial stenosis. Treves made a very careful search for stricture of the intestine caused by typhoid ulcer and was able to find only one well authenticated case. Typhoid ulcers, as a rule, heal rapidly and much of the tissue destroyed is reproduced by the reparative process, leaving only a minimum quantity of connective tissue, while the healing of a tubercular ulcer is attended by the formation of an abundance of connective tissue, which subsequently undergoes progressive cicatricial contraction. The locations for the stricture are the same in typhoid and tubercular ulcers.

Syphilitic stricture.—Among the multiform visceral lesions caused by tertiary syphilis are to be noted intestinal strictures. According to Rieder ("Annual of Universal Medical Sciences," Vol. I, D. 31) the lesions causing the obstruction are most frequently met with in the upper part of the small intestine. Syphilitic stricture is not caused by ulceration but by the production of new connective tissue in the submucosa and later in the other coats. The symptoms attending syphilitic intestinal stricture indicate the existence of a mechanical obstruction without the existence of a previous ulceration, as is the case in tubercular stricture.

Ovarian tumor.—The differential diagnosis between a tubercular stricture and intestinal obstruction caused by certain anatomico-pathologic forms of ovarian tumor is attended by many difficulties. In one of Czerny's cases of ileo-cecal tuberculosis, the swelling was mistaken for an ovarian tumor by the attending physician. Veit has shown that in women the differential diagnosis between tuberculosis of the ileo-cecal portion of the intestinal tract and ovarian tumor which has extended to the meso-cecum and mesocolon is always extremely difficult and often impossible.

Malignant stricture.—The two causes which give rise to intestinal obstructions most likely to be mistaken for each other, are cicatricial stenosis following tubercular ulcer and malignant stricture. The ileo-cecal region is the favorite locality for both of these affections. In intestinal obstruction due to either of these causes the clinical history is characterized by a

complexus of symptoms pointing to chronic obstruction, and in either case involvement of the mesenteric and retroperitoneal lymphatic glands is sure to occur sooner or later. Tubercular strictures are found most frequently in persons below middle age, while carcinoma is more likely to occur in persons of advanced age. The reverse may, however, be the case, as intestinal tuberculosis may attack the aged and intestinal carcinoma may occur in young adults. The detection of a tubercular focus in another organ, and the discovery of tubercle bacilli in the stools will furnish evidences of the tubercular nature of the obstructive lesion and will exclude the probability of the existence of malignant disease.

PATHOLOGY OF TUBERCULOUS GLANDS OF THE NECK; THEIR EARLY AND COMPLETE REMOVAL.

BY ERNEST LAPLACE, M.D., LL.D.

PROFESSOR OF SURGERY AND CLINICAL SURGERY IN THE MEDICO-CHIRURGICAL COLLEGE; SURGEON TO THE PHILADELPHIA AND ST. AGNES HOSPITALS.
PHILADELPHIA, PA.

That form of adenitis so frequent during adolescence and middle age, wherein tubercle bacilli invade the lymphatic glands of the neck, is one of the most important pathologic conditions which come to the observation of the surgeon. The infection of tuberculosis, and its local development in the lymphatic glands of the neck, naturally presents the strongest grounds for fearing the dissemination of the infection to other and more important structures in the body. These enlarged glands may retain their hyperplasia a varying length of time, but during this time the toxins generated on the spot are absorbed to the detriment and weakening of various structures in the body. The subsequent acute infection, due to streptococci, invades the tuberculous gland, transforming it into an acute abscess, which sometimes brings a spontaneous termination of the tuberculous development. This lymph-adenitis may be limited to some of the superficial or may exist in the deeper lymphatic glands of the neck. The glands grow to the size of a walnut, a group of which would produce a tumor of varying dimensions, but sufficient, by size and compression of surrounding structures, to give through mechanical, aside from its pathologic effects, excessive trouble to the patient.

The superficial as well as the deep lymphatic glands are affected; of the superficial set the most frequently affected are the sub-maxillary lymphatic glands that are situated in the digastric triangle, beneath the body of the lower jaw, also the vertical set of superficial glands of the neck, four to six in number, known as a superficial cervical chain, which are situated chiefly in the posterior triangle of the neck, along the course of the external jugular vein, between the platysma and the deep fascia. The small superficial glands in front of the neck between the hyoid bone and the sternum, and posteriorly from the trapezius muscle are also affected. Among the deeper lymphatic glands of the neck invaded by tuberculosis, we find both the upper and lower set involved. The upper set extends along the course of the internal jugular vein from the base of the skull to the level of the thyroid cartilage. When

these are involved adhesions join these glands to the surrounding structures, and considerable risk is involved in their separation from the deep jugular vein. The lower deep cervical glands follow the course of the internal jugular vein, from the thyroid cartilage to near the clavicle. These receive the lymphatics from the lower portion of the neck, and also from the esophagus and superficial cervical glands. Both the upper and lower set receive the efferent vessels from the lingual, internal maxillary and post pharyngeal glands, being deep lymphatic glands of the head; these receive their lymphatics from the tongue, mouth and nose. We here have direct anatomic reason for tracing these infections of the lymphatic glands of the neck, to the invasion of the lymphatic system by tubercle bacilli through the nose and mouth.

Granted the initial infection, it is easy to understand the resulting hyperplasia. The bacilli are found in the lymph channels between the acini of the glands and, developing there, they generate a toxin, which by its irritation causes a proliferation of the endothelial cells. There is likewise a proliferation of fibrous tissue in the stroma, but not commensurate with the growth of epithelial cells. This process generally starts about the center of the gland, and during the first stage presents a hyaline appearance; subsequently as the infected cells die away, these undergo caseation, or fatty degeneration. It is at this stage that the secondary infection of the streptococci may take place and result in the suppuration of the glands. If we analyze this process, we find a great analogy with the tuberculous process in the lungs, where a cheesy tubercle may occupy one or many trabeculae and subsequently suppurate under the infection of the germs of the atmosphere, producing an abscess cavity. Such an abscess about the neck often leads to further infection, and certainly lowers the vitality of the patient, predisposing him to other infections of deeper structures. Our modern views of infection of any kind points to the necessity of destroying foci of infection, and leads us to the conclusion that the tuberculous glands should be removed at as early a date as possible, provided they have not shown a tendency to subside under the ordinary treatment.

That a tuberculous process should be removed we have no doubt, and the manner of its destruction or removal is what we now propose to discuss.

Two great methods are in vogue to-day; one consists in exciting violent inflammation within the gland whereby the tuberculous process may be checked. This consists in the injection of an emulsion of iodoform in glycerin, or a solution of iodoform and ether. There is no doubt that in certain cases of inflammation of the superficial glands of the neck this treatment will conquer the disease, but cases are rare, and cure at best can never be gauged from the first. The inflammatory reaction may be very severe, and on subsiding may leave a further tuberculous condition. Again, the application of this treatment to the deeper lymphatic glands is fraught with danger from the possibility of injuring the deep jugular vein, the carotid artery, and other structures. At best, even if the process of tuberculosis stopped, a fibrous mass would be the result, retaining in a measure the appearance of a fibrous growth, and not constituting at any time a perfect cure. We do not mean to condemn the treatment, but do believe that it is not a direct means of fulfilling the indications in the case.

We have always advocated the complete dissection and removal of these tuberculous glands, believing that the sooner such foci of disease are removed the better. The patient can convalesce and regain health under the influence of general tonic and hygienic treatment.

In every case which presents itself we try to locate the anatomic relation of the glands to the surrounding tissue, and direct our efforts accordingly toward dissecting out all of the infected glands. It would be useless to describe the care with which dissection should be made in view of the liability to wound the jugular vein; suffice it to say that throughout this delicate work great care should always be taken to see the work as it progresses. Adhesions are such, at times, that it is impossible to distinguish the outlines of the gland from the surrounding tissue, which might have gathered within itself some important deep structure. Of material help for the safe dissection of these growths is the use of curved scissors, which, by keeping their concavity upon the growth, gives us the greatest safeguard against cutting outside of the growth. Should, unfortunately, the jugular vein be wounded, it is our practice to clamp it, and to allow the clamp to remain *in situ* twenty-four hours. In every instance we packed the wound with iodoform gauze until granulations covered the wound. Patients always stand the operation well and seem to improve in general health rapidly.

The main contra-indication to the operation is the presence of tubercular disease in the lungs. I believe it not good practice to remove tuberculous glands of the neck under these circumstances, for it seems that after the operation the lung trouble takes on redoubled activity in its development. It would seem that the removal of one would concentrate the whole development of the trouble in the remaining focus. With this exception we advise the complete eradication of tuberculous glands. Having followed this practice for many years and having observed in various hospitals, and in private work, over 200 cases, submitted to operation, we believe that this treatment is most in accord with the modern development of bacteriology and surgery.

It is not easy to make a differential diagnosis of tuberculous adenitis from the various growths that invade this locality. For a long time tuberculous lymph-adenitis was known as scrofula. To Koch belongs the credit of establishing these growths as a mere form of tuberculosis.

The conditions likely to be mistaken for tuberculous adenitis would be, malignant lymphoma, known as Hodgkin's disease. In this condition there is a general enlargement of the glands around the neck, and possibly in other portions of the body also, for it is a local manifestation of a pseudo-leukemia. The patient is extremely pale and other structures may be involved. Tuberculous adenitis should be differentiated from a lympho-sarcoma, and secondary metastatic lymphoma, both of which are malignant and can be recognized as such from the rapidity of their development and invasion of surrounding tissues. Syphilis also manifests itself in the glands of the neck, but the process is slow and would involve a greater number of glands of both sides at the same time. Tuberculous glands on the contrary are likely to be limited in number, although they sometimes appear on both sides of the neck simultaneously. The growth is rather slow. At first the gland seems movable, but

as it develops it appears more and more fixed. It is not necessarily accompanied by great pallor, nor does it cause much pain. In fact, in the history of many cases, these tumors retain a certain size for months, without showing any change, and without appearing to give the patient much trouble, except in the gradual weakening effect which they bring on to the general system.

The prognosis in uncomplicated cases of tuberculous adenitis is favorable. Patients improve rapidly in general health and maintain this improvement. In but a small proportion of cases do we see a new development of tuberculosis in the glands of the neck after the operation.

As far as deformity incident to the operation is concerned, should the surgeon exercise an ordinary amount of care the result will not be ungainly. We can often apply a subcutaneous suture which will bring the surface epithelium in absolute apposition, and leave but a very small trace of the operation. When this is compared with the ugly and distorted scars which result from only having allowed these glands to suppurate, there is no doubt that, considering the cosmetic result, the advantage lies altogether in the clean excision of the gland, with an accurate approximation of the lips of the wound. As a rule the wound can be maintained in an aseptic condition, and no pain is experienced at any time after the operation—an element which should commend itself to all those afflicted with this condition. I have no hesitation in advising the operation under all circumstances to young or old, believing it to be the safest way to remove this tendency to further tubercular infection, supplementing this procedure by the ordinary hygienic and tonic measures.

DISPOSAL OF THE STUMP IN APPENDICITIS OPERATIONS.

Read at the Tenth Annual Meeting of the Southern Surgical and Gynecological Association held in St. Louis, Nov. 10-13, 1897.

BY WILLIAM D. HAGGARD, JR., M.D.

Associate Professor of Gynecology, University of Tennessee; Adjunct Professor of Gynecologic and Abdominal Surgery, University of the South; Fellow of the Southern Surgical and Gynecological Association; Member of Alumni Association of the Woman's Hospital of New York, etc.

NASHVILLE, TENN.

No achievement so fittingly typifies the triumphs of the last decade as does the mastery of the most important surgical lesion in the abdomen—inflammation of the vermiform appendix. In 1886-7 Fitz, Sands and Weir made the epoch-making contributions to the diseases of the right iliac fossa that lifted them from the doubt of misconceived pathology and placed them in the pale of surgical resource. In 1889, McBurney completed the last link in the chain of its natural history by recognizing the necessity for prompt surgical interference and advocating its more general practice. Since then every shade of opinion in the spectrum of logic has been entertained. No subject has ever so engrossed the energy of surgeons whose individual experiences have been so keenly scrutinized, and yet whose results have been so positive and convincing. This subject can not be trite on account of its great seriousness. The contributions to its literature make a niche in surgical history replete with continuous endeavor and adorned with unprecedented success. I preface the consideration of one practical phase of the subject by the recapitulation of some facts which

constitute our beliefs. Appendicitis is pre-eminently a surgical lesion. The moment the diagnosis is made, it should become the object of the closest surveillance. In its diagnosis, surgical opinion as to its accuracy, by one who is familiar with its manifestations, is paramount. It was said of the lamented Agnew that in his intimate knowledge of anatomy, the integument to him was transparent. In diseases of the appendix its possibilities are so erratic that the most expert may not be able to accurately estimate its extent, but diagnosticians trained in its observation may recognize its presence with precision and certify its dangers. I believe in the teaching of Morris, that an infected appendix should be isolated surgically as an infectious disease is isolated hygienically. An infected appendix will extend to other tissues—infectious diseases will extend to other individuals. That many cases of appendicitis will recover without operation will not be controverted, but it is a task of the utmost discrimination and the gravest responsibility to attempt to designate such cases. One can never say with assurance which case may get well and which case may rapidly get worse and demand operation so imperatively that they would die without it. This is the type of cases that if delayed die with it.

Mayo Robson says: "Immediate operation as soon as the diagnosis is made, as originally advocated by McBurney, is better than individualizing or operating when it seems necessary." When it seems necessary, is synonymous with wide-spread infection. Willy Meyer asserts that "in 100 cases treated by immediate operation as soon as a probable diagnosis is made, more cases will be saved than out of an equal number of cases operated when it seems necessary."

An attempt at refinement in the operative indications may be thus summarized: Acute onset, with rapid pulse and considerable localized tenderness requires immediate operation; where a more gradual commencement, pulse under 100, and the early appearance of tumor, may more safely wait for the formation of competent adhesions and subsequent simple evacuation of abscess. Progressive increase of pulse rate, temperature and tenderness, makes early operative intervention imperative, while a gradual subsidence of these signs postpones such measures.

Distended abdomen, vomiting and rapid pulse signalizes extension or general peritonitis. While these cases require the most desperate surgery, Robson has saved five out of six cases of general peritonitis, and many American surgeons have rescued cases where pus ran out on both sides of the table. In chronic relapsing or recurring appendicitis the indications are most positive. It is almost the universal consensus that after one attack (Meyer) or more than one well-marked attack (McBurney) operation should be done, to anticipate another. While an individual may have one, two or four mild attacks, any of these or the next may be so serious as to jeopardize life and make an operation so imperative and under such critical conditions that it will do little else than accentuate the danger of delay and the necessity for operation in the interval after one frank attack.

In the pioneer days of appendicitis work, when the operation was only undertaken in the presence of supuration, the appendix was entirely gone or was not sought for. Indeed the question of prolonged search and removal of the appendix in abscess cases is one of the few remaining moot questions in its treatment and has to be answered by the individual convictions of the operator.

Since surgeons have assumed the responsibility of doing operations for appendicitis that are surgically safe and less dangerous than an ordinary attack left to itself or treated medically, it behooves them to perfect every detail in the operative technique to the end that they do not mix danger with beneficence. The principal step in this operation that makes it distinctive is the disposal of the stump after amputation of the appendix.

In the early deliberate operations for the removal of the appendix surgeons were content to ligate it as they would an artery. The protruding mucous membrane of the stump was cauterized with carbolic acid, the Paquelin cautery or a bichlorid tablet. Unlike the ligation of an artery, instead of the sterile fluid that organizes behind the constriction, the fluids or contents of the appendix are constantly saturated with numerous species of virulent micro-organisms that find an admirable pabulum in the compressed area under the ligature. This method was supposed to have its analogy in the ligation of the pedicle of an ovarian tumor, but we know now that it is wholly different from tying an aseptic stump for hemostasis. It likewise finds no analogy in the ligation, for ablation of the appendages, which have no connection with the intestines, can not be inverted and are usually sterile or are capable of being made so. Moreover, Morris has compared ligation of the appendix to ligation of the end of the colon after lateral anastomosis. They are structurally similar, and what would be unsafe in one would be unsound in the other. Approximation of the serous coats in both is the logical procedure. Subsequent perforation after simple ligation occurred sufficiently often to cause abandonment of that method. The custom of inverting the stump into the caput coli superseded the original crude device of dropping the pedicle. This has also many modifications and is the accepted way of disposing of the stump. It was characterized by Price, early in the history of its adoption, as "the good way." It is practiced in varying completeness from simple invagination into the cecum, to the elaborate technique of Van Hook, which consists in amputating the appendix between a temporary ligature around the base of the appendix and artery forceps, distally. The stump is cauterized with carbolic acid and a row of Lembert sutures is passed from side to side, the temporary ligature of appendix being removed before the sutures which invaginate the appendix are tied.

Dawbarn introduced the neat and efficient purse-string suture. It encircles the base of the appendix within a radius of a quarter of an inch, passing through the serous and muscular coat of the cecum. The appendix is cut away about a half an inch from its junction, stretched with small forceps, which push it into the intestine and are withdrawn as the suture is tightened around the vanishing stump. The acme of refinement in appendix surgery was reached when the method of section through the peritoneal coat, excision of mucous membrane, and suture of opposing serous and muscular coats came into vogue. This method may or may not be combined with invagination. Personal modifications of this plan have given the brilliant results of Murphy and Morris, and in the hands of the expert, leaves nothing to be desired.

The cautery method minimizes the danger of infection from the stump, and is the one which McBurney commonly employs. The appendix, after its detach-

ment from its mesentery, is amputated a quarter of an inch from its base. The edge is held up with forceps, a probe passed through the opening of the stump of the colon, to test its permeability, and a fine Paquelin cautery point inserted into the lumen of the stump. The ligature is then applied around this cauterized area, the ragged edge trimmed and freshly cauterized.

The proverbial untrustworthiness of a thermo-cautery has ever been the *bête noire* of the practical surgeon, and any method which includes its employment is not congenial.

Some of the failures from inversion of the stump, which caused consecutive perforation, fecal fistula, and sometimes death, in operations of otherwise favorable import, were due to a stricture-dam between the ligature and proximal opening of the appendix. This condition manifestly duplicates the essential condition for a continuance of all the possibilities for evil of the original attack. The operation was imperfect—a mere resection of the disease, leaving the actual and active causal factor uncanceled. These facts have led McBurney to test the patency of the lumen of the stump with a fine probe after amputation and before ligature and closure. When leaving a stump this should invariably be done.

The ideal of all surgery is completeness and applied to the surgery of the appendix would suggest total excision of the entire organ. This ideal method has been approached by McBurney in his recommendation to "cut away the appendix very close to the colon, and that portion of the wall of the colon which includes the orifice should be depressed with a probe and the edges of the furrow thus made sutured with a double row of fine catgut or silk."

In spontaneous amputation of the appendix by necrosis near its base, I have seen this method practised with success. The efficiency of peritoneal suture of gunshot or stab wounds of the intestines no doubt suggested to many surgeons a similar closure of the orifice in the cecum left after complete excision of the appendix. It has remained for Deaver to practice this method, as a routine, in suitable cases, and in its more general adoption I believe will consist the last step in the evolution of the treatment of the stump. The technique, as employed by Deaver is as follows: After freeing the appendix from adhesions and meso-appendix, the cecum is stripped of its contents and grasped between the fingers and thumb of the left hand; the appendix being held up with forceps by an assistant, is cut off flush with colon. The rent at the site of its former junction is united by continuous Lembert sutures, just as in a gunshot or stab wound of intestines, while the cecum is still held securely with the left hand. They may be disposed in two layers, the first uniting the edges of the wound, the second approximating the peritoneal covering of the cecum over it.

This method aside from its completeness, is particularly useful when the appendix is densely adherent throughout its length. A temporary ligature to the distal side allows of division at its base, and disposal of the proximal end at once. Subsequent detachment of the organ itself from base to apex can be accomplished with great facility. This method is not applicable to all cases. When the cecum is tied down by adhesions, it is impossible to bring it into the incision, which is the essential requisite in preventing the escape of any of its contents, and necessary to the careful suturing of the cut end. Where the

appendix has its origin behind the cecum, the carrying out of this technique would expose the patient to the danger of infection. Total excision of the appendix and closure of the hole in the head of the colon, does away with the following dangers: 1, subsequent perforation of the stump under the ligature from infection in its own cavity; 2, abscess of the wall of the cecum from invagination of an infected stump; 3, continuance of the infectious process from a stricture dam in the stump between distal ligature and proximal opening of appendix into cecum; 4, imperfect invagination with incomplete drainage of the stump, on account of cecal wall being thickened and stiffened with inflammatory exudate; 5, infection in base of appendix, not apparent macroscopically.

I have employed this method in five cases in the last few months, with entire satisfaction.

Case 1.—Mr. A. S., salesman, was stricken with acute pain Saturday morning, Feb. 15, 1897. Sunday noon pulse was 120, temperature 100, with rigidity of right abdominal wall and great tenderness. Operation within the hour disclosed partial sloughing of the appendix at the base. It was encased in a layer of lymph that could be stripped off like an umbrella case. The remaining attachment to colon was severed, and the edge trimmed and united by two rows of Lembert sutures, gauze drainage, recovery.

Case 2.—Joe L., aged 9, woke with pain in right iliac fossa, vomiting, diarrhea. Household remedies for colic were given. Next afternoon he was seen by Dr. T. P. Crutcher. Temperature and slight tenderness continued. Third day noticed pain in right iliac region, on attempting to run out to see a passing fire engine. Fifth day he was brought to my office, pulse 120, temperature 102, pain at McBurney's point marked, limped and inclined to right side on walking. Morning of operation on sixth day, temperature was 99, pulse 88; pressure in opposite flank occasioned pain in appendical region. McBurney's cross incision was made. Appendix was ulcerated through in center and enclosed in small pocket of sero-pus. Gauze protective pads were applied. Appendix was amputated between ligatures below perforation, meso-appendix ligated with silk, stump excised; cecum was closed with Lembert sutures; Morris gauze in gutta-percha drainage wick was placed at lower angle. Incision was closed in layers with chromicized catgut. Recovery was unnoteworthy, save for tardy closing of drainage sinus. Silk ligature was discharged through small persisting sinus seven weeks after operation; rapid healing ensued.

Case 3.—J. D., physician, age 42, had first attack twelve years ago, four attacks since: the last one two months before operation. Three or four days before the operation he had another attack, which reached its acme just prior to operation. Temperature ranged between 102 and 103, pulse 115 to 120. He has had noticeable tenderness since the first attack, greatly aggravated in the last attack. I assisted Prof. Paul F. Eve in the operation.

Through long incision, a large mass was found in the iliac fossa, which enclosed an abscess cavity ruptured during manipulation. Adhesions were separated, and appendix as large as a little finger was isolated. It was amputated at junction with colon, and resulting rent closed, gauze drainage, through and through suture, uneventful recovery.

Case 4.—Mrs. R., age 22, had tenderness in appendix region discovered in pelvic examination, during treatment for movable retroversion. I advised rest and composure. She was seized with nausea on the way home, and sat down on the pavement and vomited. Two hours afterward tenderness was more marked, nausea continuing; pulse 68, temperature 99.3. Mercurials were given, followed by salines next morning, at which time pulse was 66 and temperature 100. In consultation Dr. McCampbell related a mild attack in February, 1897. Operation was performed twenty six hours after onset of symptoms, July, 1897, McBurney incision. Appendix was thickened, stiffened, inflamed and adherent at tip. It was amputated at base; Lembert closure of cecal opening; layer approximation of incision. Highest pulse was 76, never required purgative; union without redness. She sat up on eleventh day; discharged within two weeks.

Case 5.—J. R. P., age 28, traveling man, had a mild attack, February, 1897; was not confined to bed; could not ride in a buggy without painful jarring of "sore spot" in right iliac region; has had numerous slight attacks since. Oct. 23, 1897,

after a hunt, he had a chill, followed by fever, and attended with old pain in right side; third night prevented sleep. The fourth night temperature reached 102, following the chill in the afternoon, pulse 90, history of daily chills and fever. The appendix could be easily palpated, and was not very tender.

Malaria, with chronic appendicitis was diagnosed: 0.97 gram of quinin six hours before expected chill had no effect. On the fifth night, after chill in the afternoon, temperature rose to 103, pulse 102. Appendix was well marked, slightly more tender. Operation delayed twelve hours for the arrival of his physician, Dr. Curtis of McKenzie, Tenn. Operation Oct. 30, 1897. Two inch criss cross incision was made. Appendix was found thickened, and apex much enlarged. Amputation-exsection, method used with Lembert suture, layer closure and no drainage. He had a chill the first day, followed by a temperature of 103; quinin has prevented chills since, but the afternoon temperature ranges between 100 and 101, pulse from 80 to 90. Skin sutures were removed on seventh day, perfect union, no tenderness.

The following case, occurring since the paper was read, is reported as an illustration of posterior implantation of appendix, and the impracticability of carrying out the technique devised by Deaver in such cases.

Case 6.—E. G. A., student, age 18 years; in perfect health. Was attacked with pain in right iliac fossa, preceded by slight chill on the evening of Dec. 1, 1897. He was in bed next day and up the next, but had a chill and some uneasiness the third day that confined him to bed. Same night he had a very severe attack of pain, with high temperature, tenderness of the appendix region and increased pulse. Mercurials and salines were administered and hot compresses applied until the morning of December 8. After a night of considerable and continuous pain, his temperature rose to 102, pulse 126. I saw him at noon when there was very great tenderness, which was more acute near the iliac spine and in the lumbar region than at McBurney's point. Urinary suppurative conditions were excluded clinically. Temperature 102.6, pulse 128. Immediate operation advised, but was delayed until night, when he was moved to the Infirmary at 10 p.m. Before operation, temperature was 103.2, pulse 134. Free oblique incision was made. Anticipating the presence of pus, a coffer dam of gauze was carefully and completely arranged to wall off the intestines entirely. The head of the colon was found lying over a large mass, which was deliberately opened, as the danger of peritoneal contamination had been adequately provided against. A quantity of dark, thick ill smelling fluid exuded, which was instantly mopped away as it appeared. Free irrigation was made with normal salt solution. The appendix was then found under and glued to the posterior wall of the cecum. It was dissected away with ligature and scissors. A perforation was found about an inch from the cecum. The point of attachment to the colon could not be drawn into the wound for complete excision and suture, and hence was simply ligated. Peroxid irrigation of sac was followed by normal salt solution; gauze drainage was introduced; silk worm gut closure was made. Temperature dropped three degrees, and the pulse twenty-eight beats by morning. The gauze was pulled out a trifle to facilitate drainage which was not very profuse. At the end of twenty-four hours the temperature had risen again to 102.8 and the pulse from 112 to 134. All the gauze drainage was removed and the cavity irrigated with normal salt solution through a glass catheter and gravity tube. The temperature steadily went down to 100 by the morning of the second day, and the pulse to 110. The bowels moved well on the third day, and the temperature went to normal and the pulse to 90. The drainage wick was removed, and the walled-in space irrigated daily and drainage replaced.

On the fifth day fecal matter was detected in the dressings, a chill followed, temperature rose to 101, pulse to 130. It was believed that the cavity was effectually walled off, but the small drainage opening was not deemed sufficient for safety and the entire wound was opened and irrigated and packed twice daily afterward. The temperature remained between 100 and 101 until the eighth day, when it touched normal. Pulse meanwhile ranged between 114 and 138. The temperature continued to rise irregularly with an exacerbation to 102.2 on the eleventh day and vacillated from 1 to 2 degrees until the fecal discharge ceased on the twenty-eighth day, when it subsided to normal permanently. A small sinus persists at the end of the eleventh week.

SOME UNUSUAL CASES OF APPENDICITIS.

A paper read before the Columbus Academy of Medicine, Oct. 18, 1897.

BY J. F. BALDWIN, M.D.

PROFESSOR OF OPERATIVE GYNECOLOGY, OHIO MEDICAL UNIVERSITY, ETC.
COLUMBUS, OHIO.

After a surgeon has attended several hundred cases of appendicitis; after he has found the appendix on the left side of the abdomen, running up to the gall-bladder in front and to the kidney behind the colon, and even, as in a specimen in the museum of the Ohio Medical University, nicely curled up under the left collar bone; and after he has seen it discharging the abscess, resulting from its perforation, into the bowel, the bladder, the vagina, the groin, the scrotum, the lumbar region, and even perforating the diaphragm and discharging through the lung, he begins to feel a great deal of respect for this otherwise insignificant organ, and perhaps thinks that he knows a great deal about appendicitis. Nevertheless, even with such an experience, he will be constantly meeting with cases that will surprise him, and which will continue to still further convince him that the appendix, whether functioning physiologically, if it ever does so functionate, or inflamed and forming the nidus of all imaginable pathogenic microbes, or the harmless subject of debate in a medical society, is governed by no ordinary laws.

Within the last few months the writer has seen several cases of appendicitis, out of quite a number requiring operation, that presented such peculiar features as to justify their report.

Case 1.—Feb. 12, 1897, I was consulted by Mrs. H. C. Patient was aged 25 years, though looking much older, married eleven years, mother of four children, the youngest 2 years of age. Family history was negative, except that her father and mother both had some slight stomach trouble. One maternal aunt is supposed to have died of cancer of the stomach, or ulceration, at 60 years of age. Patient has had stomach trouble for at least eight years. Pain comes on immediately after eating, and continues until time for the next meal. In fact, the distress is almost continuous. Has no vomiting, no belching. Is troubled with some accumulation of gas in the bowels. Even a glass of malted milk taken at meal time will cause pain until the next meal. The pain is about the same day and night. Diet seems to produce little or no effect. Is usually constipated. Did not try to nurse her last child, owing to her ill health. Has received no benefit from any medicine which she has taken, although she has taken large amounts and in great variety. Has suffered more during the last two years, during which time she says she has lost about fifty pounds in weight.

On careful palpation I can detect a little tenderness at McBurney's point, and close questioning elicits the fact that at the very beginning of her stomach trouble she had an attack of pain and soreness low down on the right side. She was at that time unable to straighten up or move her leg without pain. On cross-questioning she is very positive that this localized trouble preceded the disturbance in her stomach. By palpation the thickened appendix can be quite distinctly mapped out. The patient was operated on February 20. Under an anesthetic the appendix was very easily outlined. On opening the abdomen the appendix was found very long, the distal extremity clubbed and thickened, with quite numerous adhesions, but none of them particularly dense. The appendix was removed in the usual way, and convalescence was entirely uneventful. Since her return home the patient has enjoyed excellent health. I have heard from her several times and her recovery has been complete.

There is no doubt that many cases of chronic indigestion are due to chronic catarrhal appendicitis, with or without adhesions. The above is quite typical, probably, of this class of cases. It would doubtless be wise to regard no examination of a dyspeptic patient as complete until the condition of the appendix has been carefully inquired into.

Case 2.—July 7, 1897, Mrs. P. K., aged 60, was seen. She

was the mother of eleven children, the youngest aged 14 years, and had always enjoyed excellent health. From her physician I learned that he had been called to see her on the evening of the preceding day. She had been sick for about ten days. Being constipated she had taken, June 27, a dose of salts. This was followed in a couple of hours by several loose movements of the bowels, accompanied by considerable pain. This pain was referred to no particular region, but was general. Later in the evening she vomited, and during the night sent for her family physician. A diagnosis of acute indigestion was made and an anodyne administered. She rested comfortably until toward morning, when the pains grew worse, being now referred to the epigastrium. She vomited several times and thought she had fever. On Tuesday, in addition to the opiate, she was given some digestive ferment and again seemed better. She rested well during the following night, though she still had some pain, but got out of bed the following morning and was able to be around until the following Sunday, when she again had an attack of vomiting. This persisted all day Monday, with some fever and more pain. Her condition continued about the same until Tuesday evening, when Dr. Cooperrider was sent for. He found her evidently seriously sick. Her legs were drawn up, countenance pinched, expression anxious, tongue dry and coated, bowels constipated, pulse 100, temperature 102. On examination of the abdomen he discovered a large, smooth, globular mass in the right iliac region. The neighborhood of the tumor seemed markedly tender, although she was at that time complaining of no special pain in this region. The muscles were rigid. Calomel and soda were prescribed to unload the bowels, and these had been freely opened when I saw her on the following day.

I found the abdomen distended, with the smooth, rounded tumor present as above indicated. The abdominal walls were quite thick, but the tumor could be pushed up to the liver, down into the pelvis, so that its lower border could be felt by the fingers in the vagina, and could be pushed beyond the median line to the left. The tumor was about the size of the two fists. First she assured us positively that she had had this tumor for several years and had supposed it was the result of having so many children.

With this history and examination, I made a presumptive diagnosis of an ovarian cyst with a long pedicle which had become twisted, with resulting peritonitis. The patient was sent to the hospital and operated upon the next morning. When under the anesthetic the outlines of the tumor could be more distinctly determined than before, and its mobility was marked. When pushed upward a band could be quite distinctly felt, seeming to come from the pelvis. It could be pushed across beyond the median line without difficulty. The diagnosis of ovarian cyst with twisted pedicle seemed to be strengthened by this examination. On opening the abdomen, however, the tumor was found to be made up of a mass of adherent intestines enclosing an appendiceal abscess. The meso-colon and mesentery were unusually long, which had permitted the wide excursions of the tumor. There were absolutely no parietal adhesions, but a general peritonitis was present. After carefully protecting the peritoneum by gauze sponges, the abscess was opened with the finger. As soon as the finger penetrated there was a hissing escape of gas, followed by a gush of foul pus. The cavity was carefully cleansed and an enterolith, about the size and shape of a date-seed, removed; the cavity was sterilized with peroxid of hydrogen and corrosive sublimate solution. The appendix was then separated from its adhesions and removed in the usual way. The perforation was near the base of the appendix. Gauze was packed into the cavity and the abdomen thoroughly cleansed. Strips of gauze were used around the seat of operation, as well as to drain the abscess cavity. The patient stood the operation well, but the peritonitis, which had already developed, continued and death resulted in forty-eight hours.

I have stated this case to quite a number of my confrères, but not one of them has even hinted at a diagnosis of appendicitis. The possibility of appendicitis was discussed by Dr. Cooperrider and myself in arriving at a differential diagnosis, but was excluded owing to the mobility of the tumor and the history of its existence for several years. It is evident that the patient was mistaken as to the long-continuance of this tumor. It is probable that her increase in adipose had been mistaken by her for a tumor, and that she had not differentiated this from the tumor which we found.

Several surgeons have operated on cases supposed

to be of appendicitis but have found ovarian cysts with twisted pedicle. I know of no operator, however, who has operated for ovarian cyst and found, as in this case, an appendiceal abscess. Yet with the history as given by the patient, I do not see how a correct diagnosis would have been possible.

Case 3.—July 12, 1897. Mrs. M. S., Mt. Vernon, Ohio, was seen in consultation with Drs. Russell and Larimore. The following history was obtained: Patient aged 40 years; mother of four children, no history of any preceding attack similar to this. Dr. Russell had known for several months that the patient had a lump in her right groin, which she told him was sometimes larger than at others. On Friday, patient was not feeling well and therefore took a large dose of salts. She had not been constipated, but felt that she needed a physic. She had four free movements of the bowels during the night, followed by colicky pains confined mostly to the region of the umbilicus. Dr. Russell saw her the next morning and prescribed a carminative mixture, which gave relief. Saturday night the pain became worse and diffused over the entire abdomen. For this he gave her a hypodermic injection of morphin. Sunday afternoon the abdomen became very tympanitic, temperature 101.5, pulse quite frequent and wiry. This condition continued until I saw her Monday noon. At this time her abdomen was enormously distended, her pulse weak, and general condition becoming rapidly desperate. The region of the appendix was not different from any other portion of the abdomen. The lump could be felt at the external ring of the right inguinal canal. This region was somewhat tender and there seemed to be a little impulse transmitted on coughing.

It was decided to make an exploration of this tumor in the inguinal canal. If a strangulated hernia should be found, this would be treated according to the indications; but if nothing were found there, then the abdomen should be opened to see what could be learned. The diagnosis of a general peritonitis was self-evident. The question was as to its causation.

Dr. Larimore proceeded to operate on the tumor in the groin. This proved to be a hydrocele of the round ligament and did not communicate with the peritoneal cavity.

Nothing having been found at this point to account for the peritonitis, I opened the abdomen. Owing to the doubt as to the cause of the peritonitis, the incision was made in the median line. On passing my fingers down toward the appendix they at once came in contact with free pus between the folds of the intestines. An incision was, therefore, made directly over the appendix, which was found gangrenous, and no attempt had apparently been made to hedge off the general peritoneal cavity by adhesions. The appendix was removed in the usual way and the abdomen cleansed as thoroughly as was possible in face of the enormous distension and the patient's desperate condition. Drainage was freely inserted, and the patient transferred to bed. Death occurred a few hours later.

Several years ago I opened an appendiceal abscess in operating on a large strangulated inguinal hernia in a very fleshy patient, but in that case the symptoms were entirely those of a local peritonitis in connection with the hernia. In this case the difficulty of diagnosis was thoroughly appreciated, and the course which was followed was adopted only after careful consideration, and is such as would probably be adopted by prudent surgeons invariably under similar circumstances.

Case 4.—July 19, A. F., aged 30, was seen. This attack had continued for about ten days, the patient having a temperature of from 100 to 102, with corresponding pulse, from the beginning. Purgatives had been given, which had acted, and morphin hypodermically as needed for pain. Patient presents a mass in the region of the appendix, though nearer the spine than usual. Abdomen is somewhat distended and quite tender. The mass is quite movable, so much so that the probable absence of adhesions was mentioned. Patient was operated on next day, at the Protestant Hospital. On making the usual incision I found no adhesions whatever in front, but a mass, evidently containing pus, between the folds of the mesentery and meso-colon. As the danger of soiling the peritoneum if the abscess were opened *in situ* was great, I placed several folds of gauze around the most prominent portion of the tumor and applied a bandage. There was a large escape of serum through the drainage thus secured, with prompt mitigation of inflammatory symptoms. July 24 the gauze packing was removed and the abscess opened. It was found to contain a small

amount of offensive pus, a gangrenous appendix, and an enterolith about as large as the end of my little finger. The cavity was thoroughly cleansed and disinfected, the appendix, removed in the usual way, and the adhesions entirely separated. A gauze drain was passed down so as to cover the stump of the appendix, to guard against infection if there should be any leakage, and the abdomen closed. Patient made an uneventful convalescence. August 14, he was about ready to leave the Hospital when I found that he had had no movement of the bowels for two or three days, notwithstanding he had been taking purgatives. He had, indeed, had some trouble in securing a movement for the preceding ten days, but had secured an evacuation on every alternate day until the time mentioned. I prescribed vigorous cathartics, which were taken through August 15, but without securing any movement. There was a great deal of pain through the abdomen, and intestinal peristalsis was very vigorous. It becoming evident that the intestinal obstruction was complete, I reopened the abdomen in the median line, August 16. The incision showed two loops of small intestine stretched across the right half of the abdomen and quite firmly adherent to the right side. These two loops were adjacent to each other. Above them the small intestines were markedly distended, below, entirely empty. These adhesions were quite firm and were broken up only with considerable difficulty. Only these two points of adhesions could be found, and these were above the site of the original incision. The patient made a prompt recovery from this second operation, although at one time he had an attack of acute indigestion which caused some anxiety lest it should be indicative of other obstruction.

Considering the extensive adhesions which frequently exist, especially in cases in which an appendiceal abscess is simply opened and drained, it seems somewhat surprising that we do not oftener have obstruction following that operation, yet in an unusually large experience with appendicitis this is the first case in which I have had that complication. In this case the adhesions which produced the obstruction reformed after the operation. At the operation all the adhesions were carefully separated.

Case 5.—July 21, 1897, Dr. Murray had several attacks of acute appendicitis, and gave a history of four years of trouble with this organ. The pain he described as that of a "hot tack" and located it exactly at the McBurney point. Operation revealed an ordinary catarrhal appendix, with some adhesions. The operation was made as usual and convalescence was uninterrupted.

His description of the "hot tack" sensation was to me original, and I include his case on that account.

Case 6.—July 21, 1897, Wm. H., presents the usual swelling of an appendicitis. Has been sick for ten days, but called no physician until today. Patient has a temperature of 100 and pulse 120. Has been in about this condition for the past ten days. An examination reveals the presence of a general peritonitis, probably purulent in character. Patient was operated upon the next morning. The operation revealed a gangrenous appendix, with a large amount of free pus in the abdominal cavity. There were no adhesions, although large amounts of lymph were present between the loops of intestine. The pus was very offensive in character. The appendix was removed, the abdominal cavity cleaned out thoroughly, and gauze drain inserted in different directions through the abdomen. Patient was in bad condition when put on the table, the eyes being sunken and surrounded by dark rings, and everything indicating impending collapse. This collapse came on soon after the completion of the operation and he died a few hours later.

Case 7.—August 3, 1897, B. O., aged 8 years, was seen in consultation with Dr. Cooperrider. The patient had been sick for three days with the ordinary symptoms of acute suppurative appendicitis with septic peritonitis. Her general condition was bad, but she was operated upon at once. Operation revealed a gangrenous appendix with general purulent peritonitis. Thorough cleansing and drainage were resorted to, but without benefit, as the patient died a few hours later. Dr. C. had not been called into the case until the third day.

Case 8.—August 3, 1897, M. H. C., male, aged 75 years, was seen in consultation with Dr. Jenkins. He was taken with appendicitis eight weeks ago. So far as could be learned, this was a first attack. There is now present a large swelling, evidently containing pus, but not particularly painful. It has, however, within a few days given him more pain and is enlarging. At this time the presenting mass was as large as a child's

head. Operation was made by the usual incision, and a cavity found containing pus. This cavity being cleaned out, I found a deeper cavity, apparently not connected with the first one. This I opened and also washed out. No attempt was made to find the appendix, as the patient was not in a condition to bear any extended operation, which was performed at night. Both cavities were packed with gauze. The general cavity of the peritoneum had not been opened. This patient made an uninterrupted recovery.

The case is of interest chiefly from the extreme age of the patient.

Case 9.—August 14, W. J. M., aged 34, fireman, was seen in consultation with Dr. G. M. Waters. Has always enjoyed good health until yesterday morning, when he was taken with some pain through the abdomen. This was supposed to be due to a little indigestion, but about midnight the pain became so severe that he went to the doctor's office, who gave him a hypodermic injection of morphin and remained with him for a couple of hours, when he became well enough to be taken home. He has been suffering all day. His temperature now (5 P.M.) is 102, pulse 120: has an anxious expression of countenance, suggestive of impending purulent peritonitis. The abdomen is tender throughout and somewhat distended. He is nauseated. He was operated upon at 8 P.M. The intestines were found covered with a light flocculent exudate, containing some pus and having a very offensive odor. The appendix was found without difficulty, having a perforation about a half inch from its tip. This perforation probably occurred at midnight, when the pain suddenly became so intense. Old adhesions partially bound the appendix down so that its removal was not easy. It was removed, however, in the usual way, the intestines carefully cleansed, the field of operation lightly packed with gauze and the incision closed, except at the point of drainage. Convalescence was absolutely uneventful.

This case, together with Cases 6 and 7, serve to confirm the fact established by the general experience of abdominal surgeons, that a general purulent peritonitis that has existed for three days or more, uniformly results fatally. In a recent monograph on this subject, Professor Abbe of New York places the maximum limit at two and a half days. I have operated on at least fifteen cases of general purulent peritonitis following appendicitis, and in none of them in which the operation was deferred until or beyond the third day have I succeeded in saving the patient. In the last case reported, and I have had numerous similar ones, a delay of twenty-four hours would have probably caused such a distribution of the infection as would have rendered operation futile. In Case 7, while it was evident that we were dealing with an extensive peritonitis, our hope was that owing to the fact that only three days had elapsed, the disease would be so localized that an operation would result successfully.

One peculiarity of Case 6 is that the patient should have lived so long, ten days, without giving evidence of being so sick as to lead his parents to send for a physician, and yet at the time of the operation the pus was distributed everywhere throughout the abdomen. The symptoms, however, had not been particularly alarming. Some years ago I saw a case in which, at the end of a week, but with an abdomen distended with pus, the temperature was below 100, and the pulse soft and 80 per minute. The patient was on the verge of collapse, and died a few hours after an operation for the removal of the pus and appendix. In another case, with a similarly extensive amount of disease, the patient had been up and around the house more or less every day and was not regarded as dangerously sick. She collapsed, however, suddenly, after a visit from her physician, and died within an hour. The postmortem examination at which I was present, revealed the existence of a most extensive purulent peritonitis, due to perforated appendix.

Case 10.—Oct. 11, 1897, Mrs. L., aged 26, was seen in con-

sultation with Dr. Leach. Had been entirely well, as was supposed, until yesterday afternoon when she was out riding with her husband. While riding she was suddenly seized with an intense pain in the lower abdomen and pelvis. Became very much prostrated and fainted away. Was taken by her husband into a house by the wayside, and after remaining a couple of hours was able to be taken home. Had several attacks of fainting during the night. Has had constant pain through the abdomen, but several paroxysms of very severe pain. Has been given cathartics, but without effect. Has vomited several times. Enemas have also been given, but with no effect. Has a babe 9 months old. She menstruated once, a few weeks after the birth of this child. Then not until June 20. Since then she thinks she has been regular. Menstruated about a week ago, but since the cessation of the flow has noticed every day a little discharge of bloody mucus. Her temperature has been found at times normal, and at other times a little above 100. It is now 100.3. Vaginal examination shows the womb pushed forward behind the pubes. The sensation transmitted to the finger is that of fluid in Douglas's cul-de-sac. Cervix and os patulous. It is not known how long this condition has existed. Abdomen is somewhat tympanitic and excessively tender, uniformly so over the lower part. No special tenderness in the right iliac fossa. On auscultation can elicit no evidence whatever of peristalsis. On turning the patient on her side there seems to be dulness in the depending portion of the abdomen. This diminishes when the patient is turned on her back. Her appearance is that of decided collapse.

With the above history and the condition of the pelvic organs, a presumptive diagnosis of hematocele from a ruptured ectopic pregnancy was made, although from a lack of history of irregular menstruation a possibility was held of shock from a ruptured abscess or similar condition.

Operation was made as soon as possible. On making the usual incision free pus escaped as soon as the abdomen was opened. This pus welled up freely. The pelvis was found full of pus. Nothing wrong was found with tubes or ovaries. On passing the fingers to the region of the appendix, that organ was found two and a half inches long, club-shaped and very much thickened and inflamed. Could find no perforation. The intestines in this region were more decidedly inflamed than elsewhere, and some lymph was present, but no adhesions whatever. After removing the appendix in the usual way, the intestines were withdrawn from the abdomen, being carefully protected by hot towels, and the entire abdomen most thoroughly flooded with hot water, the hand and arm being introduced so that all the viscera were thoroughly cleansed. The intestines and omentum were then replaced and gauze drains carefully inserted. The patient stood the operation well and when put to bed had a better pulse than at the beginning of the operation. The infection, however, had been so extensive that she never rallied, but died the next day.

The suddenness with which the symptoms appeared and the rapid collapse without perforation, render this case unique in my experience. The operation was made less than twenty-four hours from the beginning of her symptoms.

During the last twenty years I have seen a very large number of cases of appendicitis. A considerable portion of these have been subjected to operation. While I am satisfied that at least 80 per cent. will recover without operation, I am firmly convinced that if all cases were operated upon as soon as the diagnosis was made, the operation being made by competent operators and with suitable surroundings, the mortality from the disease would be very much diminished.

RUPTURE OF THE URINARY BLADDER, WITH REPORT OF A CASE OF EXTRA- PERITONEAL RUPTURE COMPLICATED WITH FRACTURE OF THE PELVIS.

Read before the Minnesota Academy of Medicine, March 1898.

BY ARCHIBALD MACLAREN, M.D.

ST. PAUL, MINN.

Rupture of the urinary bladder always had been

and is still a very serious accident. Walter Rivington, Surgeon to the London Hospital, after a careful study of the literature up to 1885, finds the records of 322 cases, with 40 recoveries. In this list there are eight recorded recoveries after intra-peritoneal rupture, six of which Dr. Rivington rejects as unauthentic. James F. Mitchell of Baltimore, in the *Annals of Surgery*, February 1898, reports ninety cases of extra-peritoneal rupture of the bladder, complicated with fracture of the pelvis, with a mortality of 83 per cent.

There are several apparent reasons for the very great mortality following this accident; 1, because any injury, which is severe enough to produce extra-peritoneal rupture of the bladder, usually fractures the pelvis. This traumatism is often associated with extensive hemorrhage, and also with shock, which, of itself, has at times been enough to cause death in the first few hours after the accident; 2, in intra-peritoneal rupture of the bladder the abdominal cavity is immediately flooded with urine, which, if septic, at once produces an acute peritonitis, but even if the urine is sterile the patient soon becomes poisoned by urinary absorption, as is shown by Coats in the *British Medical Journal* of 1894. He speaks of the difficulty of making a diagnosis of intra-peritoneal rupture on account of the frequent absence of peritonitis. He quotes several cases, reporting one of his own, in which there was no peritonitis, nor any inflammatory changes in the bladder wound, even when studied microscopically several days after the intra-peritoneal rupture. It is not clear to my mind, why the same result is not produced experimentally, but such seems to be the fact, as shown by Weggner. He injected healthy urine, in large and repeated quantities, into the peritoneal cavity of rabbits, and reports that the urine was quickly absorbed without producing any ill effects. It is probably a matter of quantity, combined with the shock and traumatism, accompanying the accident of rupture, which makes intra-peritoneal extravasation so much more dangerous than experimental transfusion.

Ruptures of the urinary bladder are of three varieties, traumatic, pathologic and idiopathic. The majority of those in the first variety, occur in patients who have been crushed under a weight, between cars or run over by some heavy vehicle, injuring the lower abdomen while the bladder was distended with urine, these cases occurring from direct violence. Henry Morris speaks of cases of indirect rupture, where the patient was thrown upon the buttocks without fracturing the pelvis.

To the second or pathologic class, belong these cases where the rupture of the bladder wall is due to ulceration and sloughing from inflammation or from pressure. Rivington reports ten cases due to the pressure of a retro-displaced, pregnant uterus, which he had seen or found reported.

In the third or idiopathic variety, a few cases only are reported by Rivington, and in these no disease was found, only over-distention. The symptoms are: 1, the history of the accident, occurring in a patient who is usually intoxicated; the intoxication itself tending to produce an over distention of the bladder. Then there is loss of ability to pass water, perhaps passing only a few drops of blood, or at most, an ounce of bloody urine; 2, pain and abdominal distention with shock, in intra-peritoneal rupture, or extravasation of urine in extra-peritoneal rupture, with or without the symptoms of fracture of the pelvis.

The diagnosis is frequently very difficult in the early stages, but it is in these very cases that there is the greatest chance for successful treatment. The diagnosis is made from the history, combined with the passage of a catheter. The catheter usually draws a little bloody urine. If a long metal catheter be used, it may be passed through the rent in the posterior wall of the bladder, as this is the location of the tear in about 60 per cent. of cases, when it may be felt through the abdominal wall or through the rectum. When the catheter passes into the peritoneal cavity a few ounces more of bloody urine may be drawn. Abdomino-rectal, bi-manual palpation will always aid very materially in diagnosis, especially in the extra-peritoneal ruptures which sometimes occur at the base.

W. J. Walsham of London, in the *Medical Journal* of 1895, suggests the injection of air into the ruptured bladder. In the few cases in which this method has been tried it has produced such a profound collapse, that, although useful, it has been abandoned. Bridden and George Heaton propose a much safer method for diagnosis which is the injection of a known quantity of boric acid solution just before the operation. If the distended bladder can not be felt above the symphysis and the same quantity of fluid, that was injected does not return through the catheter, the diagnosis is certain. The only danger of this procedure, in early cases, is that an incomplete rupture might be made complete, and in late cases, adhesions between the intestines and the bladder might be broken open.

With regard to treatment of this condition, we find that suture was first suggested by Benjamin Bell, in 1779. This was first attempted by Mr. Millett of Bartholomew Hospital, in 1876. This attempt was not successful. Sir Henry Thompson, as late as 1883, says "success can hardly be expected in suture of intra-peritoneal rupture."

The first successful case was operated upon in 1886, by Sir William MacCormac, and George Heaton believes that before this time all cases of intra-peritoneal rupture, treated by simple catheterization, with sometimes an attempt to wash out the peritoneal cavity, or treated by median or lateral cystotomy with drainage, had all proven fatal. Bridden reported to the New York Medical Association in 1895 three fatal cases, in which he had opened the peritoneal cavity and sutured the rent. The first case was operated upon the fifth day, the second eight hours, and the third thirteen hours after the injury. George Heaton of Birmingham, in the "Annals of Surgery," of 1896, reports fifteen cases of intra-peritoneal rupture successfully treated by suture up to that time, including one of his own. Deaver, in the "Annals of Surgery," of 1896, reports one case of extra-peritoneal rupture of the bladder, with suprapubic drainage, where the patient passed urine by the urethra on the fifteenth day. J. W. White, in "Dennis' Surgery," in discussing extra-peritoneal rupture, says that he "believes that suture of the bladder wound in these cases is of doubtful value." He advises a suprapubic opening for the extravasation, with perineal drainage. When there is extravasation there should be several free incisions three or four inches long. White reports a case in which he believes that an extra-peritoneal rupture healed spontaneously with the formation of an abscess which was opened in the groin some weeks later. Mitchell favors the line of treatment laid down by White,

combined with the constant use of hot water in the form of a bath. He reports two recoveries, including the one operated upon by Bloodgood, in which the patients were constantly in the hot bath for several days.

My own case was operated upon in June, 1894. The patient, Mr. C. W. R., was referred to me by Dr. A. B. Ancker of St. Paul, on the morning of June 28. The patient had been brought to the city hospital at midnight, having been crushed at 11 P. M., June 27, by the falling of a brick wall. He was recovering from the shock which immediately followed the injury. His head and face were bruised, and there was a superficial cut in the perineum. The pelvis was fractured through the left pubic bone, the jagged edges of the break being distinctly felt through the skin, one and one-half inches to the left of the median line. After passing the catheter, three ounces of bloody urine were drawn. There was an extensive extravasation of urine over the left Poupart ligament, the penis and scrotum were both swollen and edematous. The patient was immediately etherized, and an incision four inches long was made over the most prominent point of extravasation; considerable bloody urine was found in the wound. The fracture of the pelvis was continuous with the cavity formed by the extravasation of urine. A perineal section was made and a drainage tube left in the wound.

The boy's temperature was 103 and pulse 150 very soon after the operation. A broad hip band was applied to lessen the movement of the fractured pelvis; both the suprapubic and perineal wounds were kept open for drainage three weeks, after which time they both closed and the boy passed urine through the urethra. August 1 a suppuration at the site of the suprapubic wound necessitated its being reopened and drained. The drainage, however, was imperfect, and the boy commenced to have an evening temperature of 101, which continued until September 15, when what appeared to be a large retro-peritoneal abscess, extending as high as the lower border of the left kidney, was opened in the lumbar region and thoroughly drained. It was not possible at that time to demonstrate any connection between this abscess and the bladder wound, but such a connection, no doubt, existed. The evening temperature immediately dropped to 99, and the patient soon entirely recovered. October 15 he came to my office, wearing a broad hip belt. He had gained twenty pounds in weight and was able to walk a little without crutches. The next year he was able to play base-ball very creditably, and also became a long-distance rider. I have seen him during the last year, and his recovery is apparently perfect in every way.

A REPORT OF TWO CASES OF GANGRENOUS PANCREATITIS WITH DISSEMINATED FAT NECROSIS.

Read before the Chicago Pathological Society, Feb. 14, 1898.

BY HERMAN A. BRENNECKE, M.D.

FORMERLY INTERNE IN COOK COUNTY HOSPITAL, CHICAGO, AURORA, ILL.

While on the house staff of the Cook County Hospital two cases of gangrenous pancreatitis came under my observation. Although the knowledge of pancreatitis has greatly increased during the past few years instances of this interesting disease are still so infrequent that the following cases are deserving of report:

Case 1.—Susie L., age 47, white, married, Irish; was admitted to the service of Dr. J. B. Murphy June 7, 1897. Her father and one sister died of tuberculosis, the mother is still living and well. The patient is the mother of three children and has had two miscarriages. The last labor occurred twelve years ago and in all labors the puerperium was normal. The menses were always normal. She denied all syphilitic history. Her daughter informed us later that for the past nine years she had been drinking brandy to excess. The patient informed us that she had had "Bright's disease" for the past few years and had been in the "Sisters' Hospital" for the same. Otherwise her health had always been good. Her present illness began five days before entrance to the hospital. While going to market she was seized with severe cramps in the abdomen and "fell to the ground." She had to be carried home and was given morphin hypodermically repeatedly for the pain, which was severe enough to prevent sleep. At the onset she also had a chill and vomited several times. The bowels were constipated for the first five days. The sharp, piercing pains had recurred several times; they did not radiate in any particular direction and were located in the epigastric region.

Status present.—The patient is well nourished, the face flushed, the conjunctivae subicteric; the pupils are equal and respond to light and accommodation. The nose and ears are negative; the pulse is rapid and weak (124); the chest is symmetric; the respirations are shallow and somewhat rapid (30); the lungs and heart are negative; the abdomen is distended, tympanic and very tender; in the right hypochondriac region there is an area of increased resistance. The tenderness, though general, is most marked in the epigastric region; no evidences of syphilis were found; an examination of the urine showed the following: acid, straw color, specific gravity 1012, slight amount of albumin, a few hyalin casts but no sugar. During the course of her illness several examinations for sugar were made but none was found.

The patient would not consent to an operation until three days after her admission to the hospital. After the usual preparations for laparotomy had been made the patient was anesthetized with ether. A vertical incision about three inches long was made in the right hypochondriac region directly over the indurated area. The parietal peritoneum was sutured to the skin. The intestinal coils were found matted together by a fibrinous exudate. The omentum in this region was hyperemic, thickened and studded with small grayish areas; they were situated in the substance of the omentum and not raised above its surface; they varied in size from that of a pin head to that of a pea. The peritoneal cavity contained considerable clear, straw-yellow fluid. After walling off the peritoneal cavity with iodoform gauze a large gauze and rubber tube drain was inserted. A small piece of omentum was ligated off and excised for microscopic examination, which showed that the grayish areas were typical foci of fat necrosis, such as are seen almost without exception in cases of pancreatitis. The wound was dressed daily. After the operation the patient suffered less pain for a time. The dressings were always found saturated with a clear fluid. The borders of the necrotic tissue became rough and raised, and showed other signs of sloughing. The discharge soon contained shreds of fibrin and small masses of dirty gray necrotic tissue. The pulse remained at 120 to 130, the temperature varied between 100 and 102 and the respirations between 32 and 36. On the ninth day after admission she had an attack of sharp, cutting pains running from the lower end of the sternum to the back, which attack lasted about half an hour. At this time the facial expression was anxious, the tongue had a heavy white coat, the conjunctivae were still subicteric, the heart and lungs negative. The pain in the abdomen had stopped, though the dirty-gray discharge continued. The bowel movements were liquid, greenish yellow and contained strings of mucus. Three weeks after the operation the patient was in about the same condition. The temperatures varied greatly between normal and 103. The pulse was weaker and more rapid (130 to 145); the respirations were rapid (40 to 48), but not costal in type such as are seen in acute peritonitis. After irrigating the wound for some time it would be noticed that considerable necrotic tissue still came from the upper angle. On exploration a large cavity was found below the right lobe of the liver which extended as far as the finger could reach toward the region of the head of the pancreas. Masses of loose necrotic tissue, which varied in size from a hazel to a hickory nut, could be taken from it with the forceps. The bowel movements and urination had become involuntary and the patient was very restless. She had lost about ten to fifteen pounds in weight. Death occurred twenty five days after the operation, with symptoms of a slow form of sepsis.

Autopsy, abstract.—Studding the omentum and to a lesser

extent the parietal peritoneum, were numerous areas varying in size from those just visible to larger areas, 0.5 centimeter in diameter. Most of the areas, especially the larger ones, were surrounded by a narrow hyperemic zone. They were circular, white, well defined and not raised above the level of the surrounding tissue. Those in the parietal peritoneum were most numerous above the level of the umbilicus, but scattered foci were present here and there as low down as the brim of the true pelvis, on the serous coating of the psoas magnus and above the inguinal orifice. The intestinal coils were adherent to each other and to the omentum, but easily separated. A considerable quantity of bloody fluid was present in each side of the abdominal cavity.

The pericardial cavity contained a sanguinolent exudate; both pleural cavities contained a moderate amount of clear yellow fluid; the lungs contained a few small calcareous nodules in the apices; the heart weighed 275 grams and was flabby; endocardium, myocardium, valves and orifices showed no gross changes; there were no changes in the coronaries or intima of the ascending aorta; the spleen weighed 230 grams, large, soft and adherent to the under surface of the diaphragm; on section it showed a large white infarct the size of an English walnut; the kidneys were alike in appearance, external surfaces smooth, capsules readily removable, cortical markings fairly distinct and relations of pyramid to cortex normal; together they weighed 325 grams; the uterus was small and presented the changes commonly seen in chronic endometritis; the right Fallopian tube was dilated and contained a small quantity of purulent fluid; the liver weighed 1500 grams, was soft and light red in color; on section the lobular markings were distinct; the gall bladder contained a thin pale bile, scanty as to quantity; the common duct was patent.

The pancreas was represented by a mass of gray, granular necrotic tissue, which was easily torn in removal. The necrosis had more of a liquefactive character in the region about the head and right half of the organ. The left half was studded with numerous larger and smaller grayish districts, which at various points fused together to form still larger conglomerate grayish or grayish-yellow masses. The material composing these areas was distinctly cheesy and soft and appeared at times to be formed in part at least of retained and inspissated pancreatic secretion. In and around the pancreas considerable chocolate-colored fluid, containing masses of necrotic tissue, were found. The stomach was adherent to the spleen. Behind it was found a cavity, well walled off, which contained a hemorrhagic, semi fluid material with masses of necrotic tissue in it. The intestines showed no important changes except those incident to the peritonitis. Examination of the cranial contents was not allowed.

Anatomic Diagnosis.—Gangrenous pancreatitis, with disseminated fat necrosis; localized suppurative peritonitis, with laparotomy fistula; diffuse fibrinous peritonitis; infarction of the spleen; hydrothorax; chronic apical tuberculosis; cloudy swelling of myocardium and kidneys. Microscopic examination of the areas of necrosis in the omentum and pancreas showed the usual changes found in such areas, viz., a central district of granular non staining tissue debris, surrounded by a more or less marked zone of densely accumulated leucocytes. There were no signs of tissue proliferation about any of the areas examined.

Case 2.—William F., age 43, white, widower, Irish; was admitted to the service of Dr. J. B. Herrick, Sept. 28, 1897. The family history is negative. The patient was a railroad man and drank daily fifteen to twenty glasses of whisky as well as considerable beer. His health has always been good with the exception of an occasional "bilious attack." He denied all venereal history. His present illness began one month ago after eating a few small apples and drinking several glasses of cold beer. A few hours later, while still in the saloon, he was seized with severe pains in the abdomen. He was given several doses of morphin hypodermically as well as hot drinks containing whisky. Following this he had no bowel movements for five days and vomited everything, even water, when taken by mouth. The vomitus was never fecal. The urine, he said, was scanty and of high color. At times he referred the pain to the epigastrium, but usually to the right and left iliac regions.

Status present.—The patient is a large muscular man, weighing about 250 pounds; the skin is moist and warm; the tongue is covered with a heavy, dirty, white coat; his mental condition is good; the chest is symmetric in form, the respirations rapid and shallow (28 to 36); no adventitious signs are revealed on examination of lungs; the respiratory excursion is somewhat thoracic in type; the area of cardiac dullness is slightly increased in all directions, no adventitious sounds heard; the pulse is rapid and feeble; the abdomen is much distended and the walls thick; there was dullness in the flanks and an area of dullness in the right iliac region.

Though he did not usually complain of pain, his abdomen was diffusely tender, most marked in the iliac fossæ; numerous pigmented scars were found over the tibial region. While under observation in the medical ward his pulse varied between 116 and 120 and was very weak; the temperature was usually normal, but at times would rise to 100 and 101 degrees F.; respirations varied between 28 and 36. On several occasions he had attacks of severe prostration, characterized by the extremities becoming cold and cyanotic and his radial pulse growing almost imperceptible; at other times he would be restless and sleep but little. The vomiting was persistent; the only thing retained was whisky given in half ounce quantities. Purgatives and repeated colonic flushings failed to bring away any fecal matter. Six days after admission to the medical ward, though in a precarious condition, an operation was considered advisable and the patient was transferred to the surgical service of Dr. T. A. Davis.
